Note 1.—Volume IV (pages 1813–3628) consists of extracts from testimony and historical data in the case of United States vs. Economy Light and Power Company, and historical data from Brown's Drainage Canal; the Report of the Illinois and Michigan Canal Commissioners for the year 1900; Andreas' History of Chicago and extracts from reports of United States Engineers and certain other public documents introduced by The Sanitary District of Chicago.

Note 2.—Pages 3661 to 3765, inclusive, of Volume VI, contain the following: Extracts from a public hearing on February 23, 1912, in connection with the application of the Sanitary District of Chicago, dated February 5, 1912, for permission to divert 10,000 cu. ft. per second of water through the Chicago and Calumet Rivers; extracts from a public hearing in connection with the same application on March 27, 1912, at which representatives of the Canadian Government and various Canadian cities and interests were heard; extracts from briefs and memoranda submitted; and also certain letters, telegrams, resolutions of protest from various states, cities, chambers of commerce, associations, and individuals located on the Great Lakes and in the Illinois River valley.

UNITED STATES OF AMERICA,
NORTHERN DISTRICT OF ILLINOIS, } ss.
EASTERN DIVISION.

IN THE

District Court of the United States

UNITED STATES OF AMERICA, *Complainant,* vs. THE SANITARY DISTRICT OF CHICAGO, *Defendant,*	C. C. No. 29,019.

RECORD OF TESTIMONY AND PROOF TAKEN BEFORE COMMISSIONERS APPOINTED TO TAKE TESTIMONY IN SAID CAUSE.

New York, February 15, 1909.

Deposition of Alfred Noble of New York City, taken before John A. Shields, Esq., United States Commissioner, pursuant to stipulation hereto attached.

Appearances:

James H. Wilkerson, Esq., Frank R. Reid, Esq., for the United States of America.

John C. Williams, Esq., for Sanitary District of Chicago.

ALFRED NOBLE, being duly sworn, testified as follows:

Examined by Mr. Wilkerson.

Q. What is your full name?
A. Alfred Noble.
Q. Where do you live?
A. New York.

Q. What is your address, residence address?
A. Residence, 501 West 120th.
Q. And your office address?
A. 315 Fifth avenue.
Q. What is your business?
A. Civil engineer.
Q. What position do you now hold, if any?
A. Chief engineer of the East River Division of the Pennsylvania Tunnel & Terminal R. R. Co.
Q. How long have you held that position?
A. About seven years.
Q. What has been the scope of your work in that position?
A. Well, it comprises in the first place the excavation of the Pennsylvania station between 9th and 7th avenues, and the construction of a retaining wall around the site and the building of tunnels from a short distance east of 7th avenue to Long Island City and the approaches and the terminal yard connected therewith.
Q. That has occupied the principal part of your time during the period mentioned?
A. Yes.
Q. Have you been engaged in any other work?
A. I was a member of the consulting board for the Panama Canal.
Q. What was the scope of your duties in that position?
A. To make a recommendation as to whether the sea level or summit level canal should be adopted.
Q. During what period were you occupied with that work?
A. For four or five months into the fall and early winter—fall of 1905 and early winter following.
Q. Prior to your taking your present position in what work as engineer were you engaged—what position did you fill in a general way?
A. I was in charge, local charge of the St. Mary's Falls Canal and River.
Q. During what year?
A. 1870 to '82. I was then on various bridge works as resident and assistant chief engineer for about 10 years—for about 12 years. I was a member of the Nicaragua Canal Board in 1905 and of the United States board of engineers and deep waterways from '97 to 1901, and with the Isthmian Canal Commission from '89 to 1902 or '03.
Q. With reference to the positions in which your duties brought you in contact with the Great Lakes, I wish you would

state a little more in detail just *what* the scope of your work was and what—in a general way what line of work you did?

A. The St. Mary's Falls Canal had been built by the State of Michigan and paid for by land-grant made by the United States and opened for navigation in '55, and the general government took in hand in 1870 the enlargement of the canal and the building of a new lock and sundry improvements in the river channels to obtain a greater depth for navigation.

Q. Well, you had some other positions, had you not, which brought you in contact with work in connection with the lakes?

A. I was a member of the board of engineers on deep waterways, charged with the duty of surveying a ship canal route from the lakes to tidewater.

Q. During what period?

A. That was from '97 to about '01.

Q. I would like to have you state a little in detail the general nature of your work in that connection.

A. The principal part of the work was in surveying routes from Lake Erie, one from Lake Erie to Lake Ontario and from Lake Ontario there were two routes, one ascending to the Oswego River and crossing over the summit to the Mohawk at Rome and on the Mohawk to Schenectady, and thence across country to a point on the Hudson River a little below Albany, together with an alternative route from the Mohawk all the way down to the Hudson River and continuing far enough down the river to obtain a depth of 30 feet to the sea.

Q. (By Mr. Williams.) What was that depth?

A. To obtain a depth of 30 feet. The other route followed the St. Lawrence to Lake St. Francis, and then across country to the lower end of Lake Champlain, thence via Whitehall and Ft. Edward; thence down the Hudson to the junction of the route first described.

Q. (By Mr. Wilkerson.) I direct your attention particularly to the subject of hydraulic measurements on the Great Lakes and on the inter-lake outflow of rivers, and I ask you what connection, if any, you have had with that matter?

A. The board of engineers had measurements taken of the outflow of Lake Erie and Lake Ontario, and through the United States engineer's office in Detroit the outflow from Lake Huron. This constitutes about all the work of that kind that I have been connected with.

Q. Now, over how long a period has your study and your

work in connection with the matters about which you have been testifying extended?

A. Well, I first became interested, particularly interested in lake and navigation matters in 1870 and my work at St. Mary's Falls Canal was directly connected with that until 1882.

Q. Would you say your study and work in connection with those matters has been fairly continuous since that time—that is, kept you in touch with the subject since the time that your connection first commenced?

A. Yes, sir; that is the case.

Q. You say that is the case?

A. Yes, sir.

Q. In connection with your profession are you a member of any association or society?

A. I am a member of the American Society of Civil Engineers.

Q. And have you held any position?

A. I have been president.

Q. During what period?

A. During the year 1903.

Q. Did you have any occasion in connection with that association to make any study of any question connected with the Great Lakes?

A. The president of that society has to present an address to the society about the middle of his term of office, and my subject was the Commercial Development of the Great Lakes—in the main historical.

Q. Of what college are you a graduate?

A. University of Michigan.

Q. And you hold your degrees from the institution, I suppose?

A. Yes, I obtained the degree of Civil Engineer when I was graduated and had the honorary degree of LL. D. since that time.

Q. Basing your answer on your experience and on your knowledge of matters connected with the Great Lakes and navigation, and assuming that a certain definite quantity of water as, for example, 4,000 cubic feet per second is diverted from Lake Michigan at Chicago, I ask you to state what, in your opinion, would be the effect of that as to the lowering of Lake Michigan?

A. I think it would lower Lake Michigan.

Q. Assuming that there was a definite lowering at a point

in Lake Michigan as, for example, 10 miles from Chicago, I ask you to state what, in your opinion, would be the relation of that lowering to the lowering which would take place in other bays and harbors of Lake Michigan and Huron for the whole area of each lake and at the head of St. Clair River?

A. I think there would be the same amount of lowering that occurred at the point 10 miles distant from Chicago.

Q. I ask you to state why you make that answer?

A. The stage of the lake—other things being equal, the stage of the lake is determined by its outflow and by the area of its outlet channels, and if a certain amount of water is diverted in a new channel the lake would fall until a normal discharge through the former channel is reduced by the amount diverted.

Q. What do you mean by the word lower used in that connection?

A. Lower than it would have been without the new diversion.

Q. Do I understand you to mean that as you use the term lowering would take place even though the lake may be actually higher than it was before the diversion of the water took place?

A. Yes.

Q. That is to say, you speak of lowering not with reference to a fixed mark, but with respect to the level that the lake would have in the absence of the diversion?

A. Yes, sir, precisely.

Q. I ask you to state whether or not, in your opinion, it is possible to divert a given amount of water from Lake Michigan at Chicago as, for example, 4,000 cubic feet per second, if the outflow of the St. Clair River goes on permanently undiminished precisely the same as before the diversion was begun?

A. The surface would be lower until the outflow from Lake Huron was less by 4,000 feet than the outflow would have been if the diversion had not been made.

Q. That is to say, I understand you mean that when the lowering effect of the diversion is accomplished the outflow in the St. Clair River would be 4,000 cubic feet per second less for exactly the same conditions of net supply than it was before?

A. Yes.

Q. What do you mean by the term net supply as used in this connection?

A. The amount of water to be disposed of by outflow; the inflow, less the evaporation and absorption—that would be the same.

Q. Can you make that explanation of the term net supply any fuller by the use of an example or illustration?

A. Well, the gross supply is the amount of water coming into the lake, that is the amount flowing in from the surrounding country plus the amount falling on its surface. Those are the main features at least, and a portion of that escapes from the lake by evaporation, and the remainder would pass through the lake by discharging at its outlet, and the remaining portion which is ultimately discharged from its outlet would be equivalent, I should say, to its net supply.

Q. What effect, if any, would the diversion of the water—

A. May I extend that answer, I don't know that this—that the amount discharged is equivalent to the net supply during any given period, though it ultimately becomes that.

Q. What effect, if any, would the diversion of the water from Lake Michigan at Chicago have upon the rainfall, evaporation, absorption, running off from the drainage basin of the lakes or inflow of St. Mary's River?

A. They are all independent of that. Temporarily with the outlet so formed the outflow would be more than under normal conditions.

Q. Treating the diversion of water at Chicago as another outlet like the St. Clair River, and assuming that the net supply is unchanged by the diversion of the water at Chicago, what do you say as to the effect of the diversion at Chicago upon the outflow of the St. Clair River?

A. The outflow of the St. Clair River would be reduced by the amount of the diversion.

Q. What is the effect of the reduction of that outflow upon the level of the lake?

A. I think the situation is reversed. The lowering of the lake reduces the outflow. A diversion of water through an additional outlet would cause a lowering of the lake until the total amount discharged through both outlets becomes the same as would have been discharged from a higher or normal level through the original outlet, and the amount of discharge through the St. Clair River, other things remaining unchanged, dependent upon the stage of the lake, the outflow to the St. Clair would be reduced in the case supposed.

Q. And how long will the lowering go on?

A. Until—it will go on until that condition is reached in

which the discharge of the St. Clair River is less than normal discharge—less than the discharge would have been without the diversion by the amount diverted.

Q. I show you, Mr. Noble, a chart or plat of the river, which I ask now to have the commissioner mark Exhibit 1 of this date, for identification, and I ask you to assume for the purpose of your answer that the observations which are there platted are correct. The discharge measurements therein referred to being platted with Lake height as ordinates and the volume as discharged as Abscissa. This chart shows a diagonal line threading the circles representing these observations drawn to represent or express the law of relation between lake height and volume of discharge. I ask you to examine the plate and state whether or not, in your opinion, that diagonal line drawn to express that law is accurately drawn or correctly drawn (showing)?

A. It seems to me to be accurately drawn.

Mr. Williams: Do I understand now that the answer is for the purpose of indicating the correctness of the plate as an abstract proposition to show the law?

Mr. Wilkerson: I think my question is plain. We are assuming—I am asking the witness to assume the correctness of the observations.

Mr. Reid: That is, lake measurements.

Mr. Wilkerson: On the plate are platted the lake height and the volume of discharge. The line which is drawn through these observations is a line to represent the law of relation between lake height and volume of discharge, and I am asking him for his best opinion as to whether or not that line is correctly drawn.

Witness: It appears to me to be correctly drawn.

Q. Now, assuming, always for the purpose of your answer, the correctness of these observations, I ask you to state whether or not, in your opinion, the line as there drawn expresses correctly the law of relation between lake height and the volume of discharge?

A. I think it does.

Q. I direct your attention to the fact that some of those observations are represented as squares while others are represented as circles. Would you say substantially the same if you were to exclude the observations put down as squares, those being the observations for 1908?

A. That would make very little difference in the position of the true line.

Q. I put to you the same question, the difference being that in the answer the observations which are platted as triangles as included would that make any substantial difference?

A. It would make no substantial difference.

Q. It appears, I think, from the plate that the parts platted as triangles are for 1901?

A. Yes.

Q. I will ask you to take the line embracing the law of relation between lake level and outflow, and assuming the correctness of the observations upon which that law was based, I ask you whether you can give to us a formula or equation which expresses the relation between outflow through the St. Clair River and lake level; that is to say, I want you to explain how you would determine the change in the lake height for a given change in outflow?

A. I would determine from the diagram the change in outflow to the change of height in the lake of one foot, which could be done intimately on the chart, divide by it the suggested change in the outflow and it would give the corresponding change in elevation of lake surface.

Q. Can you state a formula which could be used as the basis for that determination? If so, how would you express it, explaining the terms which you use in the formula?

A. If by Q we designate the outflow of the lake with the surface of the lake at elevation H, and by Δ Q the increase or decrease of outflow, for an increase or decrease in height of lake surface of Δ H, and by I the increase or decrease of outflow for an increase or decrease of one foot in lake elevation, then Δ H equals Δ Q divided by I.

Q. Can you make a statement of that formula or law, Mr. Noble, in less technical language assuming that you were explaining the ultimate effect on the lake level in terms of volume of diversion and the increment: by increment I mean the change corresponding to the foot's change in lake level?

A. The diagram or chart shows or states that the change of outflow corresponding to a change of elevation of lake of one foot as 23,820 cubic feet per second, and by measuring this on the chart—I assume that that is substantially correct—the change of height of lake corresponding to any assumed change in discharge is given by dividing the amount of the assumed change by 23,820.

Q. Will the result be expressed in fractions of an inch?

A. That would be expressed in fractions of a foot. It would be expressed in feet rather than in inches.

Q. Directing your attention again to the plate, Exhibit No. 1 of this date for identification, calling your attention particularly to the portion thereof headed "Scale showing loss of level in Lake Huron corresponding to the loss of outflow on St. Clair River by reason of the diversion at Chicago," assuming for the purpose of your answer, the correctness substantially of these observations and basing your answer upon this law expressed by the diagonal lines as they are drawn, what do you say as to the correctness of that scale; the scale that I refer to is the one at the left hand of the plate?

A. That scale shows the resulting changes in height correctly.

Q. Still having in mind this law or formula of expressing the ultimate effect on lake level of the diversion, what is the lowering of Lakes Michigan and Huron in inches for 10,000 cubic feet diversion?

A. About five inches.

Q. Now, you have given the answer with reference to the diversion of 10,000 cubic feet per second in Chicago, is that true proportionately for the diversion of smaller quantities than 10,000 cubic feet?

A. It is.

Q. That is to say, what would be the lowering for the diversion of 5,000 cubic feet?

A. Five thousand would be one-half of five inches or two and one-half inches.

Q. And 4,000?

A. Two inches.

Q. Can you explain that a little further, Mr. Noble?

A. The lowering of lake level due to the diversion of 10,000 cubic feet per second would be about 10/25 of a foot.

Q. (By Mr. Williams.) That is assuming that a diversion of 23,000 and some odd figures there causes a fall of a foot?

A. Yes.

Q. That is, you always assume that to start with?

A. Yes. Assuming the correctness of this chart the fall for the diversion of 4,000 cubic feet per second would be about 4/24 of a foot.

Q. Between 4/23 and 4/24?

A. Yes.

Q. (By Mr. Wilkerson.) If a certain quantity of water is

diverted at Chicago through the drainage canal what will be the effect ultimately upon the outflow of the Niagara and St. Lawrence Rivers?

A. It would be the same reduction in outflow.

Q. What would be the effect on the Erie?

A. Lake Erie would fall until its discharge was less by the Chicago diversion than the discharge that would have occurred without that diversion.

Q. What would the effect be on Lake Ontario?

A. The same.

Q. What, in your opinion, would be the effect upon the St. Clair River, Lake St. Clair, Detroit River, Niagara River, St. Lawrence River and St. Mary's River?

A. They would all be lowered; the St. Mary's River below the falls.

Q. I show you, Mr. Noble, plates which I ask to have marked Exhibits Nos. 2, 3 and 4, respectively, for identification of this date—assuming for the purpose of your answer the substantial correctness of the observations platted, I ask you to explain to us as an engineer what those plates represent and to give us a statement as to the correctness of the law or formula as represented by the diagonal lines on each one of the plates, and, if you will in explanation of the plates, I will ask you to make your answer rather complete so that we will have translated in a less technical way the meaning of those plates?

A. I have examined the three charts referred to and in my judgment the lines representing the relation between the height of the water surface and discharge is substantially correct.

Q. Directing your attention to the scales at the left hand side of each of those plates, I will ask you to make the same examination that you made with reference to the scale on Government Exhibit No. 1 for identification and to state what is the fact with reference to their correctness?

A. They are substantially correct.

Q. That answer applies to each one of the plates, does it, Mr. Noble?

A. Yes.

Q. Giving to the letter Q and H and Δ Q and Δ H, the same significance that was given to them in the plate Government Exhibit No. 1 for identification, I ask you to examine the formulæ which appear on each one of those plates and state the fact as to the correctness or incorrectness of that formu-

læ as expressed in the changed relations represented by each of the plates.

A. The formulæ express the relation between the change of height and the change of discharge correctly, assuming the correctness of the lines—the diagonal lines—on the several charts.

A. And I understand you to say that assuming in each case the correctness of the law representing these changed relations as indicated by this diagonal line you find the scales on the left hand side of each of the plates correct as representing those changes in inches?

A. They are.

Q. I also understand you to give it as your view that the lines are substantially correct, assuming the correctness of the observations?

A. Yes; the correctness of the observations and the platting thereof.

Q. So that if the observations were correctly made and are correctly platted on each one of these Exhibits Nos. 1 to 4, respectively, the scales at the left hand side of each of those plates are correct?

A. Substantially correct.

Hearing adjourned until Tuesday, February 16, 1909, at 10 o'clock a. m., at 315 Fifth avenue.

New York, February 16, 1909.

Present:

The Commissioner and counsel as before.

Hearing resumed at No. 315 Fifth avenue, New York, pursuant to adjournment.

ALFRED NOBLE, recalled:

Direct Examination Continued by Mr. Wilkerson.

Q. Directing your attention again, Mr. Noble, to the relation between discharge and height of lake, I want to ask you this question: Assuming that running over a number of years you have a series of measurements representing the discharge and height of lake, could you give a method of reaching a formula which would express the relation between those two?

A. The first part of the method would be to plat the observations on paper ruled at right angles so that horizontal lines,

for example, would represent stages of the lake, and the vertical lines represent discharges; and a line can be drawn by the eye, which is probably the way in which I would do it with my limited knowledge of the art, which would represent as fairly as I could make it an average of these observations. That is sometimes done by more accurate methods, with which I am not thoroughly familiar.

Q. Having drawn that line, then what would be the next step?

A. Then you could read from that diagonal line the relation between the stage of the lake and the discharge.

Q. Just what would that line represent?

A. Represents the relation between those two factors.

Q. Directing your attention again to Government Exhibits Nos. 1, 2, 3 and 4, I ask you what you have to say of those with reference to the method of determining this relation between lake height and discharge; in other words, what have you to say as to those charts as representing a method of reaching a conclusion on that subject?

A. The diagonal lines on those charts seem to me to represent fairly that relation between height of lake and discharge.

Q. And are those lines drawn in accordance with the methods which you have indicated as you would do if you had the series of observations?

A. I don't know that. They are substantially the lines I would draw if I were to draw lines representing that relation. They would not differ substantially.

Q. I am, of course, assuming the correctness of the observations and assuming that they are correctly platted as we did yesterday.

A. Yes; I am also assuming that.

Q. Assuming that the observations are substantially correct and that they are correctly platted, in order to get an expression of that relation the method you would follow is the one that has been followed in the preparation of those charts?

A. I don't know as to that.

Q. I mean drawing the lines.

A. Drawing a diagonal line on some basis or other is what I should do. But I should probably draw the line by eye and I should draw it with the limited range of observations and the limited range of lake levels represented by these observations and draw it as a straight line, and its position would not differ materially from the position shown on the charts or chart.

Q. What experience have you had in connection with the measurements of Lake Erie on this matter of height of the lake and discharge?

A. Gaugings were made of the outflow of Lake Erie and the upper end of the Niagara River under the general direction of the United States Board of Engineers on deep waterways, of which I was a member. The work was carried out by Mr. E. E. Haskell, who was engineer in charge, with Mr. Shenehon and Mr. Stewart as assistants in the various parts of the work.

Q. What was the result of that work? Tell us all about it as far as you know.

A. Measurements were made under the direction of that board—were taken from the International Bridge at Buffalo, and measurements were made by the Haskell current meter.

Q. What was the increment as the result of that work?

A. The curve drawn to represent the result of those gaugings—the line drawn to represent the relation between stage of lake and discharge was drawn as a curve, having a slight curvature, and from different portions of the curve the relation between height of lake and discharge varies slightly—increment I should say varies slightly; the varyings in the two portions of the curve which I measured were from 22,000 cubic feet per second for a change of elevation of one foot to 24,800 feet a second.

Q. What period did the observations on which that computation is based cover?

A. I could not answer that without referring to the records. It might have continued some months as I recall it.

Q. Do you know anything about lake observations having been made there and if so what would be the effect of those lake observations on the precision of drawing the degree of accuracy which you could make a statement as to?

A. In the reports of the chief engineers are given statements in regard to the subsequent gaugings, the important ones being taken 2,000 and 3,000 feet below the International Bridge, and the relation between height of lake and discharge is substantially the same as in the first series of observations.

Q. Referring again to the diversion of water from Lake Michigan at Chicago, what would be the effect of that diversion upon the available power of the Niagara River?

Mr. Williams: We have reserved in the stipulation objections as to that.

Mr. Wilkerson: As to the competency, materiality and relevancy of the testimony.

A. The effect would be to reduce the amount of water power available.

Q. And with reference to the St. Lawrence River?

A. The same result in kind.

Q. Have you given consideration, Mr. Noble, to the matter of data regarding the evaporation and the use of data of that kind in any attempt to detect presence or absence of the effect produced at the lakes by the diversion of the water made at Chicago?

A. It doesn't seem to me useful and it seems to me to be entirely unnecessary.

Q. Will you state the grounds upon which you base that answer?

A. The withdrawal of water through a new channel is the only new condition introduced in the case. Suppose we have only to deal with the results of the new condition, the evaporation, the inflow are not in any wise changed.

Q. What is your general information on the subject of the accuracy of data with reference to rainfall and evaporation—the degree of accuracy?

A. I do not understand that rainfall observations have been made, or evaporation observations in detail over the whole Great Lakes territory, and I should think a large percentage of doubt would exist in any figures that might be used in that connection.

Q. In your opinion are the figures relating to rainfall and evaporation sufficiently accurate so that they may be used as an element in reaching any correct conclusion on the subject whatever?

A. I should think they are not definite enough or accurate enough for use, and if they were definite and accurate they would be absolutely unnecessary I think for the purpose of determining the changes of elevation of the lake due to the diversion of water through new channels.

Q. You are familiar, I think you said yesterday, with the hydraulic measurements which have been made in the St. Clair River. I wish you would give us your judgment as to the scale on which these measurements were made and as to the competency of the persons who directed the making of those measurements.

A. I think those measurements were very carefully done by people who are exceedingly competent to make them.

Q. Do you know who made them?

A. I think the first St. Clair measurements, if I remember rightly, were made by Mr. Sabin, either by Mr. Sabin or Mr. Shenehon. My recollection is that they were made by Mr. Sabin.

Q. What do you say with reference to the skill with which the measurements of the Niagara River were made and the competency of the person under whose direction those measurements were made?

A. I think they were made with skill and by competent persons.

Q. By men qualified to do the work and giving as accurate results as could be obtained under the circumstances?

A. I believe so.

Q. What do you say about the measurements of the St. Lawrence River?

A. The same.

Q. And the St. Mary's River?

A. The same.

Q. Have you any opinion as to the degree of precision with which this line representing relation between stage of the lake and discharge has been drawn—I refer to the percentage of accuracy?

A. I should think that the lines drawn would represent the results of the observations as platted within about 1 or 2 per cent. and within the range of the observations themselves.

Q. What is your judgment as to whether or not the lowering of the lake level, as you have used that term, about from two to three inches is a material or substantial modification of the navigable condition of the lake?

A. I should expect the reduction of that amount to really effect the loads that ships could carry.

Q. In a substantial way?

A. I think in a substantial way, yes.

Q. Explain that if you will?

A. Well, in a rough way and as an approximation, the loads one of the largest class of lake freighters would carry would be reduced about 60 tons by the inch reduction in draught.

Q. You determine tons by what pounds?

A. Twenty-two hundred and forty pounds to the ton.

Q. Have you any knowledge on the subject of the expense of operating vessels of different draughts, whether if you in-

crease the draught of the vessels two or three inches it would cost very much more to operate it or not?

A. I don't see how it could effect the cost of moving a ship a mile, for example, but I have never figured it out with any degree of precision.

Recess until 2 o'clock p. m.

After recess:

ALFRED NOBLE, recalled:

Cross-Examination by Mr. Williams.

Q. Mr. Noble, assume a diversion of water at Chicago sufficient to lower the level of Lake Michigan one foot, what in your opinion would be the effect, if any, on the depth of water in the Gulf of St. Lawrence?

A. I couldn't say; it would be a very small allowance.

Q. In your opinion would there be any proportionate effect.

A. No; I should think not. Not appreciable by any ordinary methods.

Q. Assuming the same state of facts in a diversion sufficient to lower the level of Lake Michigan one foot at Chicago, what would be the effect, if any, on the depth of water in Lake Superior?

A. I don't think that it would be appreciable. I don't see how that could affect Lake Superior.

Q. What would be the effect on the depth of water in Lake Huron?

A. I think it would be a foot.

Q. Practically the same effect as on Lake Michigan itself?

A. The same effect as on Lake Michigan itself.

Q. What would be the effect in your opinion on the depth of water in Lake St. Clair?

A. I don't know. I haven't studied that matter and I don't know.

Q. Would it be more or less in your opinion?

A. I have no opinion on that point.

Q. You have no opinion then as to whether or not the effect on Lake St. Clair would be greater or less than on Lake Huron?

A. No; I couldn't say from my own studies and reading.

Q. Have you an opinion, and if so what is it, as to the effect on the depth of water in Lake Erie under such conditions as I have mentioned as compared with the effect on Lake Michigan?

Mr. Reid: You are now talking about a foot diversion?

Mr. Williams: Yes.

A. I should have to think that over; I couldn't answer it offhand.

Q. Would you be able to state without very much figuring whether the effect would be more or less in Lake Erie, for instance, than it would be in Lake St. Clair—the effect of the diversion at Chicago I am speaking of?

A. I think that question ought to be readily answered if one had time to look over the data and do the necessary figuring, but I couldn't tell it now.

Q. Would you be able to state whether or not the effect of such a diversion at Chicago would be more noticeable, more or less noticeable in Lake Ontario than in Lake Erie—by the word noticeable I mean would it affect the depth of Lake Ontario more or less than it would Lake Erie?

A. I think I shall have to make the same answer as before. That answer does not seem to be a difficult one to give if one could look over the figures with a view of ascertaining that, but I have not.

Q. I am not asking for figures.

A. I know, but still it involves the same sort of consideration.

Q. In your opinion would a diversion of water from Lake Michigan at Chicago sufficient in extent to cause the lowering of the levels of Lakes Michigan and Huron to the extent of one foot be likely to lower the level of any of the Great Lakes, or the rivers connecting the lakes to an extent greater than one foot?

A. I would not want to answer that offhand.

Q. I will ask you whether or not you have an opinion, and if so, what it is, as to the effect of the diversion of water at Chicago sufficient to lower the level of Lake Michigan one foot on the depth of water in the St. Clair River?

A. That involves the same sort of consideration as the other questions.

Q. And you would give the same answer?

A. The same answer, yes.

Q. And would you answer in a similar manner the same

question with reference to the Detroit, Niagara and St. Lawrence Rivers?

A. Yes.

Q. Suppose there were a diversion of water from Lake Superior sufficient to lower that lake one foot, what in your opinion would be the relative effect on the level of Lake Huron?

A. If applied instantaneously, the effect would be the raising of Lakes Huron and Michigan, which I assume to take place simultaneously, being proportioned to the sum of the areas of those two lakes to Lake Superior.

Q. The diversion assumed is not a diversion of Lake Superior into Lake Huron, but a diversion of water from Lake Superior; suppose it were of a nature similar to the diversion which has been spoken of here at Chicago?

A. I should think the effect of reducing the inflow into Lakes Huron and Michigan would be, so far as I see, equivalent to like a withdrawal through another channel from Lakes Michigan and Huron.

Q. If the diversion was sufficient to lower the level of Lake Superior one foot, can you give us an opinion as to how much that would lower the level of Huron?

A. That involves so much more data than I have that I couldn't answer that.

Q. Would that effect be contingent upon the discharge of the two lakes in any way; that is, if you knew the distance of Lake Superior and the discharge of Lake Huron, would that assist any in forming an opinion as to the relative effect of the diversion of this water from Lake Superior?

A. That would be pertinent to a study of the subject certainly, but I hesitate to say; I don't want to give an answer offhand. The effect of those changes takes a little time.

Q. I assume that this is a permanent diversion and I am speaking of the effect after the equilibrium has been established.

A. That would have a variable effect upon the Lake Huron. It would reduce the amount of water flowing into the lake by an amount of the diversion, and it would not be a constant and invariable reduction of the level of Lake Huron in amount; there would always be something and the variations would be constantly equalized by the lake storage feature.

Q. In your opinion would the level of Lake Huron be lowered more or less than a foot?

A. I think that matter is pretty closely determinable with a little study. While I have an impression on the subject I can hardly say it is an opinion. It is an impression which might be absolutely changed by an examination of the matter, that the effect on Lake Huron would be less than on Lake Superior. I am not very sure of that.

Q. And would the discharge of Lake Superior in proportion to the discharge through the St. Clair River bear any relation to the proportion between the lowering of the level of the two lakes—whether there is any relation at all between them?

A. A change in elevation of a foot in Lake Superior would correspond to some condition variable, depending upon the stage of the lake and still some positive difference in discharge from Lake Superior, no matter how that lowering of the surface was obtained. If that were a permanent one, or practically a permanent one, its effect on Lake Huron would be determined by the corresponding increment and discharge from Lake Huron, that is the effect such an increment or change in inflow would have upon the outflow, the increment of outflow being the same, I should say, as the increment of inflow, the amount of the change in the outflow being the same with the change in inflow that the effect upon the stage of Lake Huron would be quite determinable from the discharge curve.

Q. Suppose, Mr. Noble, that there were a permanent diversion of 20,000 cubic feet per second from Lake Superior, what would be the relative effect upon the levels of Lake Superior and Lake Huron in the case of such a diversion?

A. I don't know. I couldn't tell without referring to the data what the effect on the level of Lake Superior would be. It would fall until its outflow was 20,000 feet less than the normal outflow.

Q. Without reference to how much it would affect the level of the lake—

A. That is not a necessary feature—

Q. Can you indicate what the effect would be as compared with the effect on Lake Huron?

A. What effect the reduction of 20,000 feet in the inflow would have on the outflow?

Q. On the elevation?

A. I think that could be read so far as I see from the discharge curve. I think that would be the only disturbing element brought into the situation.

Q. Now, assume, Mr. Noble, that the discharge from St. Mary's River is 77,000 cubic feet per second and that the discharge from the St. Clair River is 197,000 cubic feet per second, would the withdrawal and diversion of 20,000 cubic feet per second have a greater or less effect upon the level of Lake Superior than it would have upon the level of Lake Huron?

A. That question ought to be easily answered with the data, but I haven't them before me.

Q. Have you given some attention, Mr. Noble, to the effect of the regulation of Lake Erie in connection with the developments of navigation?

A. That matter was taken up by the United States Board of Engineers on Deep Waterways.

Q. Of which you were a member?

A. Of which I was a member, yes.

Q. Do you recall from the investigation that you made at that time what the effect of such regulating works would be on Lake St. Clair as compared with Lake Erie?

A. My recollection—although I did not make those figures in detail—my recollection of the conclusions of the board are that about—that a change of three feet in Lake Erie would produce a change of two feet in Lake St. Clair and about one foot in Lake Huron. That is a matter of recollection.

Q. I think your recollection is very good. That was your opinion and is still your opinion as to the effect of those works?

A. Well, that is, I haven't gone into the matter since. I haven't used any of the new data which I believe exists in that connection. That was rather a rough approximation that we considered at the time.

Q. You have not, however—

A. I haven't gone into the matter since and have used none of the data collected since.

Q. So that you have not changed your opinion?

A. I should think there were better data existing.

Q. Yes; but you have not availed yourself of that data so as to change your opinion yet?

A. So far as the opinion went I think that is right.

Q. The contemplated plan suggested by your board at that time involved the raising of the level of Lake Erie 2.14 feet, did it not?

A. I don't remember that.

Q. Do you recall what the cost of the regulation was as estimated by your board, approximately?

A. I would like to have that understood that it is merely a rough estimate; I think it was eight or nine hundred thousand dollars.

Q. I will ask you in this way—

A. I can verify that very readily.

Q. I can ask you whether it was not $796,923?

A. I think that is it. It is not very far from that amount according to my recollections and I assume that it is correct.

Q. Suppose, Mr. Noble, that the outlet of any lake were restricted by an obstruction, that would result in the surface of the lake rising, would it not?

A. I think so.

Q. And then after the equilibrium had been established, the obstruction having remained there a sufficient length of time for that purpose, if the obstruction were removed the surface of the lake would then return to its original elevation, or level, would it not?

A. In time, yes; return to the elevation it would have had if the obstruction had never been introduced.

Q. Now, you testified this morning with reference to the effect of the lowering of Lake Michigan by a diversion of 4,000 cubic feet per second at Chicago.

A. Yes.

Q. Is that the basis of your testimony this morning, or was it an assumed condition of the lowering of two inches, do you recall?

A. That was yesterday. The question was in relation to the effect on Lakes Michigan and Huron of withdrawing 4,000 feet from Lake Michigan.

Q. And you testified that the effect would be about two inches?

A. About two inches.

Q. And then following that up you testified as to the effect on navigation in Lake Michigan?

A. I think some question was asked me about that subject this morning.

Q. Now, then, on what parts of Lake Michigan would navigation be affected by a diversion of 4,000 cubic feet per second?

A. It would be only in those harbors where the depth of water was near—it would apply only to those harbors where

the limit in depth corresponded closely with those on the route traversed by any given ship.

Q. Are you able to testify as to what harbors come within the purview of your last answer?

A. No, I couldn't. I don't know what the conditions are.

Q. Do you know of any harbor on Lake Michigan where navigation would be interfered with by the diversion of 4,000 cubic feet per second?

A. I am not informed as to the depth of water in any harbor on Lake Michigan.

Q. I will ask you the same question with reference to Lake Huron. Do you know of any harbor on Lake Huron that would be so affected by the diversion of 4,000 cubic feet per second at Chicago as to substantially interfere with navigation?

A. I don't recall any. I don't know the depth of harbors in Lake Huron.

Q. Without repeating the question I will ask you whether or not you can enumerate what portion, if any, of the St. Clair River would be affected and to what extent, and to a sufficient extent to substantially interfere with navigation?

A. I don't know that. I don't know of any critical point in the St. Clair River.

Q. How about the Detroit River?

A. I should suppose that at some points in the neighborhood of the Lime Kiln Crossing and Ballard's Reef might be the case in point as affecting the large commerce.

Q. Now assuming this withdrawal of 4,000 cubic feet per second in Chicago from Lake Michigan, have you an opinion as to the extent of the lowering of the level of the Detroit River by such a diversion?

A. I don't know the exact amount. That involves the same consideration as the series of questions you asked a short time ago. It is determinable, but I haven't the data before me now.

Q. Is it necessary to determine that in determining whether or not navigation will be substantially interfered with in the Detroit River?

A. That would be easily determinable relation, I should say, between the depth of water in Lake Michigan, or between the elevation of the surface of Lake Michigan and the reduction of depth at the critical point. There would always be, so far as I can see, the reduction in elevation due to the 4,000 feet less supply to the river.

Q. But until you have had the data submitted to you and you have calculated the extent of the lowering of the Detroit River you would not be able to express an opinion on the extent of the interference with navigation by that division?

A. I think it would go a little farther than I had in mind when I answered your question before. The effect on the only portion of the Detroit River that would be important in this case would follow very closely the effect upon Lake Erie, which is determinable and readily so.

Q. You have spoken of a point on the Detroit River in the vicinity of the Lime Kiln Crossing?

A. Yes.

Q. Can you state the extent of the river in miles that would be so affected?

A. I haven't that in mind.

Q. Approximately; I don't mean accurately?

A. No, I don't know that. I don't know what length of river would be affected; that would involve the question as in what part of the present channel the water is least I should say; but the effect on lowering the level, I think, could be readily determinable throughout this entire stretch mentioned within a small margin, and within that small margin I think it would be the same as that in Lake Erie.

Q. Now the, coming to Lake Erie, you may, if you will, state what harbors in Lake Erie will be so affected by a withdrawal of 4,000 cubic feet per second of water from Lake Michigan at Chicago so as to substantially interfere with navigation?

A. If that question is as to the entrance of vessels into the harbors in question I would say at once I don't know; but I think that the withdrawal or lowering of water in Lake Erie will affect all of the important navigation on Lake Erie by reason of affecting the water in connecting channels; the Detroit River, possibly the St. Clair River and pretty certainly the St. Mary's River.

Q. I understood you to say that you were not able to give any opinion with reference to any portion of the St. Clair River.

A. I am not certain about the St. Clair River. I do not recall any place there that limits the draught of vessels.

Q. The navigation on the Niagara River; would that in your opinion be substantially interfered with by the diversion of the 4,000 cubic feet per second at Chicago?

A. I can't say as to that, because I am not familiar with the depths of water in the Niagara River, but if my recollection is correct, that there is shoal water that limits them there, I should say the surface of the river would certainly be depressed by such a withdrawal from Chicago. It would be at the head of the river substantially that given by the discharge curve in question in Lake Erie, and as to whether it would be more or less coming down the river I wouldn't undertake to say.

Q. Are you familiar with the kind and size of the craft that navigate the Niagara River?

A. Not particularly.

Q. Is it not true as a general statement that it is only navigated by small craft at present, that is, that large lake vessels do not use the Niagara River for navigation purposes?

A. I am not positive as to the facts in this case.

Q. Now I assume that with reference to Lakes Michigan, Huron, Erie and Ontario, your answer would be the same, that the only portions of those lakes in which navigation would be substantially interfered with by a diversion of 4,000 cubic feet per second in Chicago would be the harbors?

A. And the connecting channels.

Q. We took this up separately. We have mentioned each one of the connecting channels.

A. Address that question again.

Q. Is there any portion of Lake Michigan, Lake Huron, Lake Erie or Lake Ontario, except the harbors and the connecting channels where navigation would be seriously or substantially interfered with by the diversion of 4,000 cubic feet per second at Chicago?

A. I think there is ample depth for navigation.

Q. Are you able from your own knowledge to state or give the name of any harbor on Lake Ontario where navigation would be substantially interfered with by the diversion mentioned at Chicago?

A. I don't know; I am not familiar with the harbors in Lake Ontario.

Q. In your opinion would navigation on the St. Lawrence River be substantially interfered with by the diversion of 4,000 cubic feet per second at Chicago?

A. The interference, by which I mean the reduction of depth for navigation over the shoal places would be affected by the withdrawal of water from Lake Michigan at Chicago.

Q. What I wish to know is if you are personally familiar

with the shoal places so that you can tell us where, if at all, on the St. Lawrence River channels would be affected?

A. I don't think I am familiar enough with the navigation of the St. Lawrence River to answer that question.

Q. This morning I understood you to say that there would be a loss by decrease of loading in vessels amounting to about 60 tons to an inch?

A. Yes.

Q. What depth or draught boat did you have in mind in making that estimate?

A. The type of boat I had in mind was one about 550 feet long and 56 foot beam, which is not the largest but one of the larger class of boats now engaged on the lakes, and the amount of the loss would not vary much; there would be quite a little change in draught.

Q. What would be the total tonnage of such a vessel?

A. The total loading, as near as I remember, would be in the neighborhood of 10,000 tons.

Q. How many feet of water would such a boat draw; what is the depth of the draught?

A. I think in the neighborhood of twenty.

Q. Twenty feet?

A. I think so.

Q. Twenty feet is 240 inches?

A. Yes.

Q. Sixty tons to the inch?

A. No; not for 240 inches.

Q. How many inches?

A. Because the boat doesn't sail along through the air when it has no load; it still draws water.

Q. How many inches?

A. I don't know that precisely. That is a very obvious consideration; I did not determine this in that way and I don't recall now what the average draught of those larger boats is like.

Q. Do you know about how many vessels there are now navigating the Great Lakes of the capacity and tonnage that you had in mind?

A. No, I don't recall; not a great many.

Q. Not a great many?

A. Not a great many, no.

Q. Suppose the water was lowered a foot instead of two inches, would that reduce the loading by the same amount?

A. Practically so. By the same relative amount, you mean?

Q. Yes.

A. Yes.

Q. You mean by relatively that it would be six times as much as two inches?

A. That is it exactly.

Q. Without reference to the loss of tonnage, 60 tons to an inch, would the loss of a foot of water, or reduction of the depth of water by one foot reduce the depth of the loading by the same amount, that is, a foot?

A. I think so. My immediate connection with those matters is, of course, pretty old, but during the time that I was directly connected with the work the skippers watched the stage very closely and took the load for every inch of water there was over the shoal places, and my information is that that is still the case.

Q. Is it or is it not true that the difference in elevation between Lakes Huron and Erie has been 9/10 of a foot less since 1886 than it was before that time?

A. It is my recollection of the situation at the time the report was written that for substantially the period mentioned the records of the stages of the lake seem to show that difference.

Q. Now then, do you know or are you able to give an opinion as to what causes contributed to that difference?

A. It is my recollection of the situation at the time speaking under the reservation of trying to recall a matter that is several years old, I believe that we—I think that we were led to believe by a comparison of the survey made before 1870 with the one made I think after the deep waterways board began its work, there is indicated an enlargement of the outlet to Lake Huron from which it was believed and I think Mr. Wisner made some calculations to show that, such enlargement would result in about the difference of level stated. I think the inference that the enlargement occurred about 1886 was based entirely upon the records of the stages of the lakes.

Q. Have we got in the record now an opinion by you as to whether or not there was such a condition to start with?

A. I don't know. My recollection is that another survey was found prior to 1886 which did not agree with the one which we used, and I have never gone into the matter since

to revise my opinion, and the effect of the new data has been to leave me in some doubt as to the old.

Q. You testified this morning, Mr. Noble, with reference to the accuracy of the discharge measurements. I will ask you to state whether or not in your opinion the discharge measurements which are taken by the government engineers and concerning which you were asked this morning are the most accurate that it is possible to procure at this time?

A. I don't know of any better way.

Q. Do you know of any other information which you would compare favorably with these in accuracy on the subject of discharge measurements?

A. That calls for a little more expert knowledge upon the subject than I have. I have read of some difference of opinion by engineers as to the precision and accuracy of meter measurements and float or rod measurements. In an ideal channel I think the rod measurement would give—I don't see why it shouldn't give at least as good results.

Q. Do you know of any other measurements being in existence on the particular channels involved here than these?

A. I think in the St. Clair River there was an old—I think the double float measurements made in the '60s.

Q. The information prior to 1898 is rather incomplete, is it not; prior to 1898 the information at hand with reference to these gaugings is rather indefinite and unsatisfactory, is it not?

A. I don't think the measurements made in the earlier days were made—of course they were not made with the whole knowledge the subject afterward acquired, but my impression is, without having the comparison before me, that the former measurements of the Niagara and St. Clair Rivers were fairly good. I don't remember now how the St. Lawrence River measurements compare, and in arriving at such an opinion my opinion would be the result of the later measurements.

Q. I just want your opinion as to the relative accuracy of the discharge measurements that are referred to in the plats exhibited to you and concerning which you have testified.

A. I would not be able to discriminate between those with the limited expert knowledge I have on the subject; they are all taken by competent engineers and during much the same period.

Q. I did not ask you to compare one sheet with another. Was that the best information so far as you know?

A. In my opinion they are the best information available without knowing exhaustively the rest of the data.

Q. Your estimates of the specific effect of the diversion of water at Chicago are based entirely upon the results of these discharge measurements, this platting produced and presented here by the government and shown as Government Exhibits 1, 2, 3 and 4?

A. Those are all that I used, I think, in estimating.

Q. And your estimates are based upon them?

A. Yes, sir.

Re-direct Examination by Mr. Reid.

Q. In regard to the last question, you have independent knowledge in regard to Lake Erie? You made measurements there independent of any charts or anything else in this case in regard to Lake Erie, did you not?

A. I don't know that I am clear as to whether you include all the discharge measurements in Lake Erie or not.

Q. The Board of Engineers of Deep Waterways made them?

A. Yes.

Q. In regard to Lake Erie?

A. In regard to Lake Erie.

Q. And you stated this morning some figures in regard to Lake Erie?

A. Yes.

Q. Now they had nothing whatever to do with these charts here?

A. I would like to examine those charts with reference to that.

Q. I say in answering the question this morning, the Board of Deep Waterways, they didn't have these charts here?

A. No.

Q. You did not have these charts Government Exhibits 2, 1, 3 and 4 in mind when you gave those figures in regard to Lake Erie?

A. No. Those figures in regard to Lake Erie —

Q. They were independent of any charts in this case?

A. Yes; they were taken from old measurements of the Board of Engineers on Deep Waterways.

Q. In regard to the effect that this diversion at Chicago would have on navigation at certain points on the Great

Lakes, you call them critical points, do you not, of navigation?

A. They can be called so.

Q. I will ask you Sturgeon Bay Canal and Green Bay Entrance and Manitou Passage as well as the mouth of the Detroit River and one end of Lake Erie as it approaches Toledo might be included as critical points and would be affected by a lessening of the height two inches or more?

Mr. Williams: I object to the question on the ground that it is leading and suggestive, and on the ground that the witness has already testified fully as to his personal knowledge of the points at which navigation would be affected.

Question withdrawn.

Q. I wish to refresh your memory in regard to some of these critical points of navigation. Can you think of any more than you stated to Mr. Williams?

A. Points in the St. Mary's River I have in mind.

Q. Any others?

A. I don't know the circumstances in regard to any others. I do not recall at this moment any other points than those in the first two streams; the depths of the harbors I am not familiar with.

Q. In your first answer to Mr. Williams you said the entrances to the harbors would be affected by this two-inch diversion and the shoals of the lake would be affected and that would affect navigation?

A. Where the depth of the water was near the critical depth.

Q. And that would be in regard to the shoals as well as in entrance to the harbors?

A. Yes.

Q. And you gave the figures to Mr. Williams as $796,923 as the amount of the cost to have the regulating works as made by your report of the Board of Engineers of Deep Waterways; now has that been revised to date?

A. Not that I know of; that is the figure given.

Q. Can you give us an estimate of how much more it would cost to complete them now than the estimate at that time?

Mr. Williams: I object to the question on the ground that it assumes that there is an increased cost since that estimate was made.

Q. Is there an increased cost now than there was at the time this estimate was made?

A. In the cost of works in general?

Q. Yes.
A. In my opinion, yes.
Q. Can you give us any amount?
A. No, I wouldn't want to do that without going over the matter in some detail.
Q. You haven't anything in mind now?
A. No, I haven't anything in mind.

Signed and sworn to before me this 8th day of March, 1909.

Hearing adjourned to February 17, 1909. at Ithaca, N. Y.

Ithaca, N. Y., February 17, 1909.

Appearances:
Frank R. Reid, Esq., Assistant United States Attorney, for plaintiff.
John C. Williams, Esq., for defendant.

Prof. EUGENE E. HASKELL, called as a witness on behalf of the plaintiff, being duly sworn, testified as follows:

Direct Examination by Mr. Reid.

Q. What is your name?
A. Eugene E. Haskell.
Q. Where do you live, Mr. Haskell?
A. Here in Ithaca, New York.
Q. What is your profession?
A. Civil engineer.
Q. How long have you been engaged in that profession?
A. Nearly 30 years.
Q. Of what schools are you a graduate?
A. I am a graduate of this college—this college of Civil Engineering—Cornell University.
Q. Do you occupy any official position in the university?
A. I am the director of the college.
Q. And what is the scope of your duties in connection with the college at this time?
A. Largely executive.
Q. How many years have you been connected with this college?
A. Since the fall of 1906.
Q. Where were you before that?
A. Engaged in practical engineering work.

Q. Where? Just generally, now.

A. I was five years on the Mississippi River; eight years with the Coast and Geodetic Survey in Washington, and thirteen years with the Lake Survey.

Q. Now, just give us an idea of what your duties consisted of with those surveys?

A. On the Mississippi River I was engaged in surveys—hydraulic surveys of the river. With the Coast and Geodetic Survey, I spent almost all my time upon the tides and currents of the coast, and the hydraulics of New York harbor, also on Long Island Sound.

Q. Have you held any position with the government—a member of any boards, rather?

A. I am at present an International Waterways Commissioner.

Q. What is that?

A. It is a commission that has to deal with matter pertaining to the Great Lakes, that is of common interest to the United States and Canada.

Q. And what in regard to the Great Lakes?

A. That is, the diversion of water and the preservation of their stages.

Q. What other experience have you had in regard to the Great Lakes?

A. I have been connected with the surveys and with the investigation of lake levels; in fact, I planned the investigation of lake levels that has been going on since 1898.

Q. Just give us, in a general way, with whom you were connected in that work?

A. With the United States Lake Survey, located at Detroit. The work really started before the Lake Survey was organized, in the United States Engineer's office at Detroit.

A. Can you name any of the individuals that assisted in this work?

A. General Leydecker was in charge of the engineer's office at the time the investigation started; he was also later in charge of the Lake Survey. In 1901, the Lake Survey was transferred to—now—Colonel Fisk of the Engineer Corps.

Q. Now, what range did your investigations cover—just a general idea?

A. A general idea?

Q. Yes. What the actual work consisted of.

A. The work consisted of—in the collection of gauge rec-

ords; that is, of the stages of water of the several lakes and of their connecting rivers, and of the measuring of the discharge of the lake outlets.

Q. Now, can you give us a general idea of where those investigations were—

A. On all the lakes and their outlets.

Q. Now, can you give us some of the outlets there?

A. The St. Mary's River is the outlet of Lake Superior; the St. Clair River is the outlet of Lake Huron; the Detroit River is the outlet of Lake St. Clair; the Niagara River is the outlet of Lake Erie and the St. Lawrence River is the outlet of Lake Ontario.

Q. What systems or devices did you use in doing this work; any particular ones?

A. Why, we designed a special self-regulating gauge for the registering of the stages of water.

Q. What is the common name of that? What is that known by; what is the name?

A. The gauge is officially known as the "United States Lake Survey self-registering gauge."

Q. That was used in all your work, was it; in this connection?

A. Well, not all of it. We had to resort in many instances to the use of staff gauges or float gauges.

Q. Now, what other instruments or devices were used in this work?

A. We had sounding machines for making soundings and current meters for measuring velocities.

Q. What were the current meters?

A. We used the meter which I designed, known as the "Haskell Current Meter."

Q. Now, these instruments and devices that you used were the best devices that could be obtained for this work, and these investigations?

A. We considered them so.

Q. Now, from your experience in dealing with the Great Lakes and the levels and the outflow and other work that you have described, have you an opinion as to whether or not the diversion of water at Chicago to the amount of four thousand, five thousand, ten thousand and fourteen thousand cubic feet per second, would in any way affect the navigable capacity of Lake Michigan, or the Great Lakes? First, have you an opinion?

A. Yes.

Q. Now, would it affect the navigable capacity of Lake Michigan or any of the Great Lakes?

Mr. Williams: I object to that.

A. Yes.

Q. Have you, or do you know of any system of measuring the amount of the decrease or effect on the lake level of a certain outflow or diversion of water through a channel, or any other means of diversion?

Mr. Williams: Objected to on the ground that it calls for a conclusion of the witness on a question which is to be determined by the court from the facts, and not from conclusions alone.

A. Yes.

Q. Now, in regard to the word "lowering" as used in connection with the Great Lakes, what do you understand that to mean?

A. A decrease in the stage of water, an actual lowering of the water surface.

Q. Just give us a further definition of what you mean. I am talking now in relation to a diversion of a body of water from a body of water, what would you mean by the lowering?

A. That is a diminishing of the stage. That is, the mean level of the lake for a certain year may be up here (indicating on blue print) and due to the diversion for the next year it might be a certain quantity lower.

Q. Now, might the lake be actually higher and still have a lowering, in the sense that you mean?

A. Yes, sir.

Q. That is what I meant.

A. Yes.

Q. If 4,000 cubic feet per second should be diverted at Chicago would that lower Lake Michigan at a point ten miles off from Chicago, and would that have an effect on all the lakes if it did affect it ten miles off?

A. Certainly.

Q. Is it possible to divert a given amount at Chicago, say 4,000 cubic feet per second, and have the outflow in the St. Clair River go on forever undiminished?

A. No, sir.

Q. And it is your opinion that it must be absolutely certain, that the lowering effect of the diversion must affect the outflow in the St. Clair River?

Mr. Williams: I object to that question as leading.

A. Certainly.

Q. Now, what do you understand by the term "net supply" used in regard to the Great Lakes and the diversion of water?

A. By the term "net supply" I should understand it to mean the supply in any particular lake that its outlet had to take care of.

Q. And even though the amount through the outlet might vary, still the net supply would always remain the same? You understand that?

A. Yes.

Q. The net supply in any way would not be altered by the diversion itself, as you understand it?

Mr. Williams: Objected to as leading.

A. It would not.

Q. Are the rainfall, evaporation and absorption of the run-off in the drainage basin of the lakes, or the inflow from St. Mary's River, increased or decreased by the diversion at Chicago?

A. Neither.

Q. Now, can you give us an example or illustration of the effect that the outflow, say, through the St. Clair River would be affected by a diversion at Chicago, in any way?

A. I don't know that I caught the first part of that question.

(Question read.)

Q. As to its less, or greater—the relative relation between the outflow and the increase?

A. The St. Clair River is the natural outlet of Lake Huron,-Michigan, and any water diverted at Chicago would mean that it must come from the discharge of the St. Clair River; must be taken from that.

Q. In your experience have you made any measurements or have you any data in which, say, was given a certain amount of outflow through the drainage canal at Chicago, that you could figure out the effect it would have on the outflow of the lake?

A. Yes.

Q. Now, just give us, in a general way, what that system is that you would use?

A. First of all, would be the determination of the discharge curve of the St. Clair River.

Q. What would that be for?

A. For the purpose of finding out the discharge of the river corresponding to any particular lake stage.

Q. You mean by that, you get a formula to use and apply it?

A. A formula or curve which would give the discharge of the river for all stage of the lake.

Q. Now, can you tell us what the lowering of Lake Michigan and Huron would be, in inches, for a 10,000 cubic feet of diversion?

A. Very close to six inches.

Q. Could you tell us what percentage of the lowering in Lake Michigan the water in St. Mary's River at the foot of the locks will be lowered?

A. The lowering of the locks would be slightly less, about 20 per cent.

Q. Would the discharge of 4,000 cubic feet per second at Chicago effect the navigability of Lake Michigan or the Great Lakes?

Mr. Williams: Objected to on the ground it is leading and calls for a conclusion. I have no objection to the witness stating, if he has an opinion, what the effect of the diversion would be in so far as the lake level is concerned, but what that effect would be on navigation—I don't understand that the witness is qualified on navigation.

A. It would lower the water on all shoal places, which, of course, would be a detriment to the interests of navigation.

Mr. Williams: I move to strike out that part of the witness' answer referring to navigation in the last sentence thereof.

Q. What places would be effected on the Great Lakes? What do you term those places where a difference of a few inches of water may make a difference

A. The lower Detroit River is one of the critical places, and all of the west end of Lake Erie. Lake St. Clair; the northern end of Lake Michigan. Certain areas in Green Bay; the head of the Niagara River, and, in fact, the Niagara River to Port Day, and the lower St. Lawrence River below the Galops Rapids.

Q. You answered a short time ago, in regard to 10,000 cubic feet per second, the diversion would be a lowering of six inches?

A. A trifle over six inches.

Q. Now, the same proportion would hold good in 5,000 cubic feet, or any amount?

Mr. Williams: I object to the question as leading.

A. Yes.

Q. If Lakes Huron-Michgan were lowered a known amount and Lake Erie a known amount, what would be the lowering in the Detroit River, Lake St. Clair and the St. Clair River?

A. It would be substantially the same.

Mr. Williams: I object to the answer on the ground that it is not responsive to the question as put, and ask to have it stricken out.

A. (Continued.) The Detroit River and Lake St. Clair would be changed by very closely the amount that Lake Erie was changed; the St. Clair River would be changed by the amount that Lake Huron was changed—or very close to it.

Q. If a certain quantity of water is diverted in the drainage canal at Chicago, how much will the outflow of the Niagara and St. Lawrence Rivers be lessened?

A. They will be lessened by the amount of the diversion.

Q. Will Lake Erie be lowered?

A. It will.

Q. And the Niagara River?

A. And the Niagara River.

Q. Lake Ontario?

A. Lake Ontario and the St. Lawrence River.

Q. Do you know anything about the hydraulic measurements that have been taken in the St. Clair River since 1897, as to how much time has been spent, and the instruments, equipment and methods used? Just in a general way.

A. That is about three years—that is previous to my departure from the Lake Survey—previous to 1906. I am not quite sure of what has been done there since that time.

Q. Now, do you know as to the equipment they had for doing that work, and as to the instruments and methods they used at that time?

A. I do. The outfit was a very complete one, and the most of the velocity measurements on the cross-section were made with two meters.

Q. What were they?

A. They were Haskell Current Meters, used in such a way as to check each other.

Q. Who was in charge of the work there?

A. Mr. L. C. Sabin for the first two seasons.

Q. And who else?

A. And Mr. Murray Blanchard for the third season.

Q. Were they competent men for that work?

A. They were.

Q. Now do you know anything about the work done in the Niagara River?

A. I do.

Q. Just give us a general description of that?

A. The discharge measurements in the Niagara River were started by myself for the Board of Engineers on Deep Waterways in 1897. These observations were made—that is, the current observations were made—by Haskell Current Meters from the International Bridge. The following season beginning about midyear of 1898, that work was taken up by the United States Lake Survey with Mr. Shenehon in charge of the work, and was continued during 1898 and 1899, and into 1900, if I remember correctly. And as a check upon the observations made from the International Bridge, a second section known as the "Open Section" was selected at a point about 1,800 feet below the bridge and the discharge measurements of the river were made on that section and the two sections compared; that is, the discharge curves as determined from the observations at the two places were compared and they agreed within about a half of one per cent., as to the volume of discharge for any particular stage of Lake Erie.

Q. You consider that as accurate as it is possible to get it?

A. It is.

Q. And the St. Lawrence River, too?

A. The discharge of the St. Lawrence River was made at what is known as the "Three-point Section," by Mr. Shenehon, covering parts of two years.

Q. The same methods and systems applied?

A. Substantially the same methods, same instruments and same outfit employed in the work.

Q. And as far as your judgment is concerned the results are as accurate and trustworthy as may be obtained, are they?

A. They are.

Q. Now, with regard to the results of the volumes of flow for the various stages of Lakes Michigan, Erie, Huron and St. Lawrence, and other things that you have testified in regard to the results, within what scale of accuracy were they—the per cent.?

A. Within 5 per cent.

Q. Five per cent., is that the result in inches, or just what do you mean by that?

A. That the results were accurate within 5 per cent. That is, that the volume of discharge, for instance, is known within 5 per cent. of the absolute truth.

Q. You testified that a diversion at Chicago would lower the St. Lawrence River a certain amount?

A. Yes.

Q. Now, what would the corresponding lowering of Lake Ontario be for one foot, suppose, between Lake Ontario and Ogdensburg—be less than one per cent.?

Mr. Wiliams: Where would the one foot be?

A. You mean for a lowering of Lake Ontario for one foot?

Q. Yes.

A. It would be about .92 of a foot at Ogdensburg.

Q. It would be less than one foot?

A. Less than one foot.

Q. I want to ask your opinion regarding the propriety of using any existing data in regard to evaporation in the attempt to detect the presence or absence of the effect already produced on the lakes by the diversion made at Chicago since 1900?

A. It is hardly permissible to use that data at the present time.

Q. Have you any knowledge as to how large the error of those figures would be?

Mr. Williams: I object to the question on the ground that it is manifestly beyond the range of human knowledge to know, if they are not reliable, how unreliable they are.

A. Do you wish me to answer it?

Q. Certainly.

A. I should think that one might easily get into an error of 20 to 25 per cent.

Q. Now, the same question in regard to the precipitation, on the drainage of the Great Lakes?

A. Precipitation is a great deal better known. I think it is safe to say that the observations of the Weather Bureau give within 12 to 15 per cent.; that is, particularly the observations made during later years.

Q. Do you know particularly the extent of the observations made by that Bureau?

A. By the Weather Bureau?

Q. Yes.

A. They now have a large number of stations in the drainage basin of the Great Lakes, of course, they began with a few when the Weather Bureau started, and these have been increased, and for the last ten years they have had a pretty good number of permanent and volunteer observing stations.

Q. It might differ—the extent on the Great Lakes themselves—there are no stations on the lakes?

A. No stations on the water surface, no.

Q. Assuming a diversion of 10,000 cubic feet per second at Chicago, how long would it take 9/10 of the ultimate lowering in Lakes Michigan-Huron, due to this diversion, to take place?

A. About four and a half years.

Q. The same question in regard to Lake Erie, and the St. Clair River and Detroit and Niagara River?

A. Take nearly six years for Lake Erie.

Q. St. Clair River?

A. You asked Ontario, did you not?

Q. Yes.

A. And about six and a half years for Lake Ontario.

Q. Have you any figures on the St. Clair River?

A. The lowering of the St. Clair River?

Q. Yes. How long will it take?

A. The time?

Q. Yes.

A. The St. Clair River is controlled by Lakes Michigan and Huron, and the time required there would be substantially the time of those lakes.

Q. Do you know the fall of the Niagara River at Niagara Falls, as to the horse-power? Can you tell us what 4,000 cubic feet would be worth in horse-power at Niagara Falls?

Mr. Williams: I object to that question.

A. That is, as to the Falls?

Q. Yes, as to its use there as horse-power?

Mr. Williams: I want to state my objections. Not on the ground of immateriality, because that can be reached later, but on the ground that nothing has appeared to show that the witness is qualified to answer the question.

A. I should have to figure that out, if you want it for the Falls. That is, if you want it for the total fall in the Niagara River.

Q. Well, could you tell us what a thousand cubic feet per second at Niagara would be in horse-power?

Mr. Williams: I object to the question on the ground it is not complete.

A. The total fall there would amount to about 3,500 horse-power.

Q. You do not know anything about the fall available at Lockport and Joliet?

A. No, I do not.

Q. What would be the lowering of Lake Erie in inches of a diversion of 4,000 cubic feet per second at Chicago?

A. Two inches.

Q. And Lake Ontario?

A. An inch and two-thirds.

Q. This is reckoned on 4,000 cubic feet?

A. Four thousand, yes.

Q. The same proportion would apply on 5,000, 6,000 or 10,000?

A. The same proportion, yes.

Q. You testified as to Lake Michigan as 10,000?

A. As 10,000, yes.

Q. The change in the elevation that you testified to in regard to the level of the lakes, that would reach into every harbor and bay connected with the Great Lakes, would it not?

A. Certainly.

Cross-Examination by Mr. Williams.

Q. Mr. Haskell, what would be the effect on the level of Lake Michigan and Lake Huron by the diversion of 4,000 cubic feet per second at Chicago?

A. Can you give me time to figure it?

Mr. Reid: I think we took it for 10,000 instead of 4,000.

A. Two and a half inches

Q. Would the same proportion prevail with a discharge of any definite amount from nothing, say, to 20,000 cubic feet per second at Chicago, from Lake Michigan? That is, what I mean is, suppose there was a diversion of any definite amount at Chicago, that amount varying anywhere from nothing to 20,000 cubic feet per second, would the same proportion of lowering of level occur in Lake Michigan as is shown by the testimony you have given based on 4,000 cubic feet per second?

A. The figures that I have stated would be for mean level, substantially the mean level of those lakes.

Q. Yes?

A. It would be slightly less for lower stages and greater for higher stages.

Q. But would the same proportion exist as between the lowering of the level of Lake Michigan and Lake Erie, no matter what the diversion was up to say 20,000 cubic feet per second?

A. I don't think I get your question clear in my mind.

Q. We have a diversion of 4,000 cubic feet at Chicago which gives a lowering of Lake Michigan as you say of 2½ inches, and a lowering of Lake Erie of 2 inches, which is practically 4/5 of the lowering which occurs in Lake Michigan. Now, suppose the diversion was in amount from nothing to 20,000, would the same diversion take place in Lake Michigan as in Lake Erie?

A. Substantially so.

Q. How far from Chicago would you say that the effect of the diversion of 4,000 cubic feet per second would be noticeable and appreciable, following the chain of the lakes and the connecting rivers toward the Atlantic?

A. It must be appreciable throughout the entire lake system, in Lakes Michigan and Huron and the entire lake system below.

Q. To the Gulf of St. Lawrence?

A. Yes.

Q. Would it be appreciable in the Gulf of St. Lawrence?

A. It would be so infinitesimal that we would say no.

Q. Would it be noticeable, the lowering of Lake Michigan caused by the diversion at Chicago of 4,000 cubic feet per second, would that have any effect upon the level of Lake Superior?

A. No.

Q. Lake Huron, you would say, was effected the same extent as Lake Michigan?

A. To the same extent; Lakes Huron and Michigan are practically one lake.

Q. Now, taking the level of the water in St. Clair River would the diversion of 4,000 cubic feet of water in Chicago have any effect upon the level or the depth of the water in the St. Clair River?

A. It would.

Q. How much as compared with Lakes Huron and Michigan?

A. Well, nearly the same amount as Huron and Michigan.

Q. Would you care to express an opinion as to the percentage?

A. I have not worked it out in that form; it would be slightly less.

Q. Then I take it from the answers that you have already given that, in your opinion, the lowering of the level of Lake Erie would be substantially four-fifths of the lowering of Lake Michigan?

A. Yes, for mean stages.
Q. Yes.
A. Yes.
Q. Now, what would you say as to the level of Lake St. Clair, as compared to the level of Lake Huron—the effect of the level with a diversion of 4,000 cubic feet per second?
A. The effect on Lake St. Clair?
Q. Yes, sir. In your opinion would it be somewhere between the effect on Lake Huron and Lake Erie?
A. Yes.
Q. It would be slightly less effect—more effect on the depth, than the effect shown in Lake Erie, and less than shown by Lake Huron?
A. Would you mind repeating that?
Q. I mean, that the effect of the depth of the water in St. Clair River would be slightly less than the depth in Lake Michigan and Lake Huron?
Q. And slightly more than the effect of the depth of Lake Erie?
A. No; slightly less.
Q. The effect would be less than the effect upon the water in Lake Erie?
A. Yes. Because Erie, to a large extent, controls the Detroit River and Lake St. Clair.
Q. Well, suppose there is a diversion of 4,000 cubic feet of water per second at Chicago, which you say effects the depth of Lake Michigan to the extent of two and a half inches, to what extent would it effect the depth of Lake St. Clair?
A. Really it would be so close to the two inches, that you wouldn't need to bother about the difference.
Q. To the two inches?
A. Yes; of Lake Erie—perhaps I misunderstand you.
Q. Well, can you give your opinion as to the precentage of the 2½ inches lowering of the lake level of Michigan appreciable in Lake St. Clair?
A. I don't know that I see—
Q. Two and a half inches is 100 per cent.?
A. Is 100 per cent.
Q. Yes, sir. Now, what percentage of that effect would be shown in Lake St. Clair?
A. Practically 80 per cent. of it.
Q. And Lake Erie substantially the same?
A. And Lake Erie substantially the same, yes.
Q. What, percentage of that variation in depth would be

found in Lake Ontario as the result of the diversion of say 4,000 cubic feet per second?

A. I don't know that I see your point clear there. That is, what percentage?

Q. Yes.

A. Of the depth at Lake Michigan?

Q. Lowering of Lake Michigan, would be noticeable in Lake Ontario?

A. Would be noticeable in Lake Ontario?

Q. By the diversion of any quantity of water at Chicago?

A. About 70 per cent.

Q. Now, take the Detroit River. Assume a lowering of Lake Michigan by reason of diversion of water to the extent of one foot, or any definite lowering, to what extent would the depth of the Detroit River be affected as compared with the effect upon Lake St. Clair, or in connection with Lake Michigan, say, in comparison with Lake Michigan? What percentage of the lowering would be noticeable in the Detroit River?

A. About 80 per cent.

Q. What percentage of the lowering noticeable in Lake Michigan by reason of the diversion of a definite quantity of water would be noticeable in the Niagara River?

A. Well, that would depend upon the point in the Niagara River.

Q. Well, what part of the Niagara River is used for navigation purposes?

A. Clear down to Port Day, which is a short distance above the Rapids that approach the Falls.

Q. And how many miles?

A. About sixteen.

Q. Well, take it at Port Day?

A. Take it at Port Day?

Q Yes, sir.

A. Are you referring to Lake Michigan?

Q. Yes, sir.

A. Forty-one per cent.

Q. After you have passed through Lake Ontario and into the St. Lawrence River, what percentage of the lowering manifested in Lake Michigan would be noticeable in the St. Lawrence River due to a diversion at Chicago of any definite quantity?

A. That is, the percentage in the St. Lawrence of that in—

Q. In Lake Michigan?

A. —in Lake Michigan. Sixty-six per cent.; that is, in the St. Lawrence River down to the Galope Rapids.

Q. And from there on?

A. From there on I don't believe I have the data that I could express an opinion on that.

Q. Would it be less than the amount above the Rapids—66 per cent.?

A. Yes. For mean stages, yes.

Q. And would that—whatever the amount you determine to be the proper percentage—would that continue without variation to the Gulf, or would the effect decrease gradually as it neared the Gulf?

A. It would decrease.

Q. Until it reached zero, practically at the entrance of the Gulf?

A. Yes.

Q. Now, Mr. Haskell, let's go back to the St. Clair River and Lake St. Clair again, and having now clearly in your mind the purport of my questions, you stated substantially that there would be no difference between the effect observable in Lake Michigan and between that in Lake St. Clair, but you showed practically 20 per cent. between Lake Michigan and Lake St. Clair; where does that occur?

A. It occurs in this way: The St. Clair River is controlled by Lake St. Clair and Lakes Michigan-Huron.

Q. Yes.

A. —while the Detroit River and Lake St. Clair are controlled substantially by the stage of the water in Lake Erie.

Q. Well, could you have a drop of any amount in the St. Clair River and not have any in Lake St. Clair?

A. No. Still it might be masked by the stage of Lake Erie.

Q. Well, assume then, that at the connection of Lake Huron and the St. Clair River the effect of a diversion at Chicago is equally noticeable in Lake Huron and in the St. Clair River, would that continue to be true through the entire length of the River St. Clair down to Lake St. Clair, where the effect is only 80 per cent. of that noticeable in Lake Michigan?

A. Yes.

Q. And the drop then from the hundred per cent. lowering to the 80 per cent. lowering is at the outlet of the St. Clair River into Lake St. Clair?

A. It is distributed along the St. Clair River.

Q. Along the entire length of the river?

A. Substantially along the entire length of the river.

Q. All right. Now, this testimony that you have given with reference to these relative lowerings in these bodies of water, applies generally without reference to any specific gauge readings or discharge measurements or anything of that kind; you give that testimony based upon your knowledge of the lay of the lakes?

A. Yes.

Q. And you do not use, in arriving at these conclusions any specific discharge data?

A. No; only what is given by the United States Lake Survey.

Q. Well, what discharge data do you take into consideration in giving this testimony that we have just been going over now?

A. The date that has been obtained by the survey and that is in their published reports.

Q. But you use the specific data that you obtain from the United States Lake Survey reports in arriving at these percentages?

A. Yes.

Q. But you would be able to testify without any specific discharge data on the general proposition of the effect of the lowering being less appreciable as you approach the Gulf of St. Lawrence, and as you left Lake Michigan?

A. Yes, sir.

Q. And without going into the question of percentages?

A. Yes.

Q. You have testified, Mr. Haskell, with reference to the substantial accuracy of these discharge measurements and gaugings of the United States Government, and as exhibited to you, and have you had your attention called to these plates shown as Comp. Exhibits 1, 2, 3 and 4 lying on the table (indicating)?

A. Yes, I think those are the same ones. (Examining plates referred to). Yes.

Q. In giving your opinion as to the effect upon the level of Lakes Michigan and Huron of the diversion of 10,000 cubic feet per second, and 4,000 at or near Chicago, you have used the data contained in these gaugings and discharge measurements of the Government?

A. Not as they are given there; that is with one exception.

Q. Now, did you prepare yourself any plates or plats from which you arrived at the conclusions that you have testified to?

A. Yes. That is, this plate here (indicating), upon which I base my testimony, is one that is used by the International Waterways Commission.

Q. By whom was it prepared?

A. By Mr. Wilson.

Q. And the data from which it was prepared was obtained where?

A. The Lake Survey.

Q. The same source of information as used for a basis for the plates that I have called your attention to, as Government Exhibits 1, 2, 3 and 4?

A. Yes. That is, we may have used less than is given there. I won't be positive as to that, but the information comes from that source.

Q. And your testimony is based upon the computations made by you from the plate which you hold in your hand?

A. Yes.

Q. And used by the International Waterways Commission?

A. Yes.

Mr. Williams: Now, I would like to have that plate marked as "Haskell's Ex. 1, for identification," and attached to the deposition, so we will have it.

Plate marked "Haskell's Ex. 1, for Identification, 2/17/09 H. J. R. on X Ex."

Q. Now, is there, Mr. Haskell, to your knowledge, any information that is complete and reliable enough so that any estimate could be made of the effects of diversion of water from one of the Great Lakes, aside from the information which you, as a member of the International Waterways Commission and the Government have used, being the gauge readings and discharge measurements of the United States Government used as a basis for these plats or plates?

A. No; I think the only information available, from which the question can be worked out, are these data.

Q. Now, are you acquainted with the fact—if it is a fact—that the difference in the elevation between Lakes Huron and Erie has been nine-tenths of a foot less since 1886 than prior to that time?

Mr. Reid: That is objected to as not being proper cross-examination.

Q. What is the difference of elevation between the two lakes?

A. I don't think it is a fact.

Q. All right; it is not a fact. Then there is no explanation necessary?

A. No.

Q. Do you know that it has been so claimed?

A. Yes.

Q. But do you not think that that is true?

A. That is, that there has been a permanent change?

Q. That since 1886 it has been—there has been 9/10 of a foot less in difference of elevation than there was preceding 1886?

A. Yes. That is, I am aware that that does exist, but it is by no manner of means permanent.

Q. Well, now then, if it does exist, how do you account for that?

A. Due to the low stages of Lakes Huron and Michigan for a considerable period of time.

Q. And do you know why—have you any opinion as to why Lakes Huron and Michigan have had that low stage?

A. Lack of precipitation.

Q. Does that condition still prevail?

A. Partially so.

Q. You testified that in your opinion the data of the United States Government obtained from the Weather Bureau and the observation points under the jurisdiction of the Weather Bureau, were inaccurate to perhaps 12 to 15 per cent.

A. 12 to 15 per cent.

Q. For how many years back would you consider that to be true?

A. I should say for the last fifteen years.

Q. In your opinion that system of observation is increasing in efficiency from year to year?

A. From year to year.

Q. And would you say that 12 to 15 per cent. applied to the whole period, or to the latter portion of the period?

A. Well, I should say for the whole period of that fifteen years.

Mr. Williams: I think that is the extent of our questions, Mr. Haskell.

Re-direct Examination by Mr. Reid.

Q. Do you know what the water movement is—that is, if Lake Erie goes down a foot, how much does the water go down at Suspension Bridge,—at Whirlpool?

A. It goes down a foot at Lake Erie, you mean?

Q. Yes. Have you figured that out? Do you know?

A. Yes, I figured it out. I could not do any more than give a guess at it, without referring to the computations. (To Mr. Wilson.) Have you got one of those diagrams here, Mr. Wilson?

Mr. Wilson: I have not; it is in the report of the Commission on the Whirlpool Rapids.

Q. Then you have not it here?

A. I have not it here.

Q. It is greater or less than one foot?

A. It is greater than one foot.

Q. Now, does the position of any one of the lakes, or a pool, prescribed its lowering—its position in the chain?

A. Prescribe its lowering?

Q. Yes.

A. Yes.

Q. Well, do the lakes lower gradually to Montreal, is that what you mean by these figures you have been giving us here?

A. Yes. The actual lowering of the level would depend upon the discharge curve, as you go east, the increment of the discharge, would be greater.

Q. What I meant is, it gradually tapers off as far as Montreal, but beyond there the volume is so large—

A. Yes, below Montreal the volume is so large, compared to the amount of diversion that the effect is less.

Q. How does the increment in the Whirlpool compare with that at the head of the Niagara River?

A. The increment?

Q. Yes.

A. That is, per foot? It would be less.

Q. You answered the question before, it went greater as it went down. Now, is that as you understand? In your answer before you said it got greater as it went down?

A. Well, this question relates particularly to the Niagara River?

Q. Yes.

A. You see it does not apply to another lake, or another outlet. The increment of discharge for any particular section—when you mention the head of the Whirlpool Rapids that is a particular section in that river.

Q. That is protected by the motion, isn't it, of the water. Would not there be some difference?

A. The section is narower; that section is very much nar-

rower; very much narrower than the river where the discharge was measured.

Q. Yes. Wouldn't the area of the section control more from the fact that it was nearer the sea?

A. No, that would not make any difference.

Q. Now, the curves upon which you base your statements as to the lowering of the lakes, does not take into consideration the measurements made in 1908?

A. No.

Mr. Williams: There is one thing I would like to have, Mr. Haskell, go into the record, the definition of the word "increment." I don't think the court will know what we are talking about when we are talking about the "increment," and somebody ought to explain it?

A. We mean by the increment of discharge the additional quantity of water that is discharged per foot rise of the particular lake with which you are dealing.

Q. You mean the per foot rise or unit rise?

A. We usually term it the "per foot," and then if we want it in small quantities, we take the tenth of it, or in inches—to satisfy the lawyers—why we take the twelfth of it.

W. EDWARD WILSON, called as a witness on behalf of the plaintiff, being duly sworn, testified as follows:

Direct Examination by Mr. Reid.

Q. What is your name?

A. W. Edward Wilson.

Q. Where do you live, Mr. Wilson?

A. Buffalo, New York.

Q. What is your business?

A. I am secretary of the International Waterways Commission.

Q. How long have you been occupied in that position?

A. About two and a half years.

Q. Have you any profession?

A. Civil engineer by profession.

Q. What school are you a graduate of?

A. Graduate of Cornell University.

Q. What other positions or experience have you had in this line?

A. Why, since 1901-02 I was in charge of hydraulic meas-

urements on the St. Marys River; in 1903 I was in charge of the hydraulic measurements on the Niagara River, and for a period of three years I was in the Rocky Mountains at that time doing hydraulic work in addition to holding a position of assistant professor of Civil Engineering in the University of Utah.

Q. Did you finish giving your experience and positions?

A. Yes.

Q. Now what connection have you had with the hydraulic measurements on the Great Lakes and on the rivers?

A. That has partially been explained in the previous answer. Do you wish it stated again?

Q. Well, just on what rivers.

A. On the St. Mary's River and some work on the Niagara River.

Q. Well, just give us a short statement of the methods and results?

A. In 1901-2 I was in charge of the work on the St. Marys River in which we took up the measurements of the discharge of this river and in 1903, I think, the work on the Niagara River consisted of slope observation. In 1908 I made an investigation at Niagara Falls as to the effect of the diversion of water as caused by the Power Companies.

Q. Do you know anything about the local conditions at Chicago?

A. Very little.

Q. Now, is it possible to divert 4,000 cubic feet per second at Chicago without lowering Lake Michigan?

A. It is my opinion that you could not divert water through the Chicago Drainage Canal without lowering Lake Michigan.

Q. What effect would that have in the bays and harbors in Lake Huron?

A. Well, eventually it would lower every bay and harbor in the lake.

Q. Now, will you give us your idea and definition of "lowering" as used in this connection?

A. "Lowering," in this case means, with me, the change in level of Lake Michigan and Huron due to diversion at Chicago compared with the level of the lake without the diversion for the same period.

Q. The level of the lake may be, in fact, higher than it was before and still there be a lowering according to this definition?

A. According to this definition, yes sir.

Q. It is possible to divert 4,000 cubic feet per second at Chicago and have the outflow in the St. Clair River go on the same, undiminished?

A. It is not.

Q. What do you understand by the term "net supply"?

A. The net supply to any lake?

Q. Yes, or as it applies to Lake Michigan or Huron. Just give us a general definition and afterwards apply it.

A. Applied to any lake, it is the total quantity of water supplied to this lake, or in other words, it is the water yield to any lake. In the case of Lake Michigan and Huron it is equal to the discharge of the St. Clair River plus or minus the storage on the lake surface, or, it is equal to the precipitation on the lake surface plus the run-off from the streams of the water-shed minus the evaporation on the lake surface.

Q. Is that a constant quantity?

A. It is not; it varies from month to month and year to year.

Q. Notwithstanding that, is it still a concrete and tangible thing?

A. Yes, sir.

Q. Are the rainfall, evaporation, absorption, run-off, in the Drainage Basin of the Great Lakes, or the inflow of the St. Marys River increased or decreased by this diversion at Chicago? It does not alter these factors.

Q. Have you any method or can you compute the effect of diversion of water from a lake as to the amount it would lower in inches?

A. Yes, sir, I can compute it.

Q. Could you tell me what the lowering of Lake Michigan and Huron would be in inches for a 10,000 cubic foot diversion?

A. At mean stage, Lake Michigan and Huron would ultimately be lowered by a diversion of 10,000 cubic feet per second, about six and one quarter inches.

Q. Now, can you give us the same for Lake Erie and Lake Ontario?

A. For 10,000?

Q. Yes.

Mr. Williams: You are speaking now of a diversion at Chicago from Lake Michigan?

Mr. Reid: Yes.

Mr. Williams: And the effect of diversion?

A. The effect of diverting 10,000 cubic feet at Chicago would eventually lower Lake Erie about five inches.

Q. And for Lake Ontario?

A. The effect on Lake Ontario would be about four and one-quarter inches.

Q. Those would hold good for the same proportions for say 4,000 cubic feet per second and 6,000?

A. Yes, sir.

Q. What percentage of the lowering in Lake Michigan will the water in St. Marys River at the foot of the locks be lowered?

A. Well, the water will be lowered at the foot of the locks an amount slightly less than that on Michigan and Huron.

Q. What percentage at the critical points, and what do you consider the critical points?

A. In the St. Marys River?

Q. Yes.

A. I should say the locks at Ste. Marie and the improved channels along the St. Marys River.

Q. You gave these figures in regard to the mean stage. Now, what would be the effect on the high stages and the low stages?

A. The effect on these lakes?

Q. Yes; as to the larger or smaller; would it be greater when they are high or low?

A. For any particular lake?

Q. Well, any of these?

A. On Lake Michigan and Huron the effect would be greater as the stage becomes less, and vice versa.

Q. If a certain quantity of water is diverted in the Drainage Canal at Chicago, how much will the outflow in the St. Lawrence and Niagara Rivers eventually be lessened?

A. The same amount.

Q. Will Lake Erie be lowered?

A. Yes, sir.

Q. And Niagara River and the St. Lawrence River, as far as Ogdensburg?

A. Yes, sir.

Q. Did you do any of the work on the measuring of the outflow of the St. Lawrence River and the Niagara River?

A. No, sir. Other than my work in 1903, which did not take into consideration the discharge measurements specifically.

Q. Where was the work at that time?

A. At that time it was carried on between Buffalo and Niagara Falls.

Q. Have you any information as to the money spent in hydraulic measurements in the St. Clair River since 1897?

A. In a general way.

Q. Did you do any specific work in that line?

A. I did not do any on the St. Clair River. I did a little on the Detroit. My work has been principally on the St. Marys River.

Q. You consider the diversion of 4,000 cubic feet per second to 10,000 cubic feet per second through the Drainage Canal of Chicago would have any effect upon the navigable capacity of the harbors or lakes or bays of that section?

A. I do.

Mr. Williams: Objected to on the ground that it calls for a conclusion of the witness, and not facts, and, on the ground also, that the witness has not shown himself qualified to testify on questions affecting navigation.

A. Continued. It would lower the water in the entire system below Superior, and naturally cause a decreased draft for vessels.

Q. Now, where in the area you speak of would this likely effect the navigable capacities of these places?

Mr. Williams: I object to that question on the ground that it assumes a conclusion which has not been shown and on the further ground that it calls for another conclusion of the witness.

A. Lake St. Clair, at the foot of the Detroit River; on the shoals of the western part of Lake Erie. It would effect the Niagara River and the St. Lawrence canals and the St. Lawrence River.

Q. I want your opinion regarding the propriety of using any existing data regarding evaporation and an attempt to detect the presence or absence of the effect already produced by the diversion made at Chicago on the lakes since 1900?

A. It is my opinion that any deduction made from observations for evaporation would not be very reliable considering the fact that evaporation varies from month to month and from year to year. ——— In some months, the evaporation on, for instance, Lake Michigan and Huron is greater than the amount of precipitation in the lake surface and run-off of the streams. That also applies to Lake Erie and Lake Ontario.

Q. Take a diversion of 10,000 cubic feet per second at Chi-

cago, how long will it take 9/10 of the ultimate lowering in Lakes Michigan and Huron, due to this diversion, to take place?

A. Michigan and Huron—a little over four years.

Q. As to Lake Erie, St. Clair River and Lake Ontario?

A. Lake Erie, 9/10 of the effect would be noticeable in five or six years.

Q. Lake St. Clair?

A. Lake St. Clair would be somewhere between the time required for the lowering of Lake Huron and Lake Erie.

Q. Lake Ontario?

A. Lake Ontario, 9/10 of the effect would occur from five and a half to six and a half years.

Cross-Examination by Mr. Williams.

Q. In making your computation Mr. Wilson, as to the effect of a discharge or a diversion of 10,000 cubic feet from Lake Michigan at Chicago, that effect being as I understand --in making the computation, whatever the result—you must compute from some basis of discharge from Lake Michigan and Huron outflow?

A. I compute that quantity from a difference in discharge per unit rise.

Q. As shown by what?

A. As shown by this plate here, (indicating).

Q. That is the plate identified as "Haskell's Ex. 1."

A. Yes, sir.

Q. And which is to be attached to the deposition?

A. Yes, sir.

Q. Well, now, you use as a basis for your computation Haskell's Exhibit 1.

A. Yes, sir.

Q. And where did you get the data that is on that chart?

A. That data came from the United States Lake Survey.

Q. And is that the same data that is used, if you know, in the preparation of the plats or plates which have been heretofore identified as Complainant's Exhibits 1, 2, 3 and 4, being the plates on the table before us?

A. The results as shown on that plate are derived from a part of these observations.

Q. Did you have any information in the preparation of Haskell's Exhibit No. 1 not used in the preparation of the

Government Exhibits 1, 2, 3 and 4; you say you have used a part of the information shown on those plates?

A. Yes.

Q. Now, did you use anything that is not shown on those plates?

A. No, sir.

Q. So that the sole source of your information from which Haskell's Exhibit No. 1 has been prepared, is from the information derived from the Lake Survey?

A. Yes, sir.

Q. And the information shown on these charts?

A. Yes, sir.

Q. Is there any other definite and accurate information upon which to base conclusions upon the subject matter which you have testified about?

A. Not to my knowledge.

By Mr. Reid: Re-direct Examination.

Q. The Complainant's Exhibits 1, 2, 3 and 4 contain some more information than you have on Haskell's Exhibit No. 1, do they not?

A. They contain more data.

Q. Yes.

A. Yes, sir.

Q. Can you give us the statement in regard to the tapering off of the lowering or the effect of a certain diversion

Q. Now Mr. Wilson, you spoke of certain gorge sections in which the general rule which you stated might be reversed?

A. Yes, sir.

that you forgot to ask it on direct, I will not object to it, but if not, I will object to it as not re-direct examination.

Mr. Reid: Yes.

A. In a series of reservoirs, such as the Great Lakes are, the effect of diversions generally decrease as they go down to the source. There are occasions, however, in which—there are sections in which—the increment, or rate of change, in discharge per unit, is greater than at some definite point located above.

Q. Now, just explain why, and any instances you think of?

A. The best example that I know of is at Suspension bridge. That section the river is very narrow so that a unit rise of the river produces as less rate of change in discharge than say, at the head of the Niagara River where the width

of the controlling section is several times greater than at the Whirlpool.

Q. In regard to Haskell's Exhibit No. 1, you told Mr. Wil-
Mr. Williams: If you are asking this question on the basis liams that you based your calculations on that. That does not take in the measurements made for 1908 does it?

A. No sir.

Re-cross-Examination by Mr. Williams.

in Chicago, and its effect as it goes toward the East?

Q. Have you in mind any other gorge section than the one mentioned by you at the Suspension Bridge in the chain of lakes?

A. There is one at the Whirlpool, that is in the Niagara River. There is another at the Rapids Plat in the St. Lawrence River.

Q. Now, take the gorge at the Suspension Bridge and the Whirlpool Rapids; is there any navigation carried on there?

A. There is a boat called the "Maid of the Mist" that navigates below the falls, but at these two sections—

Q. There is no navigation there?

A. No.

Q. And the Maid of the Mist would not be affected by the rise or fall of a foot?

A. Well, I understand that occasionally boats have gone down in that section, but not intentionally. That does not apply to the Rapids Plat; boats do navigate there.

Q. Yes, and do you know the depth of the St. Lawrence River there?

A. Well, I don't know that exactly. I know that boats draving 5 or 6 feet navigate there.

Q. Pleasure boats?

A. Almost entirely pleasure boats.

Testimony of O. H. Ernst, taken before Anson S. Taylor, Commissioner, on February 18, 1909, at Washington, D. C.

Present for the complainant: Mr. Frank R. Reid.

Present for the respondent: Mr. John C. Williams.

O. H. ERNST, being first duly sworn to testify to the truth, the whole truth and nothing but the truth, testified as follows:

Direct Examination by Mr. Frank R. Reid.

Q. What is your name?
A. O. H. Ernst.
Q. Where is your residence?
A. Washington.
Q. What is your profession?
A. I am an army officer, retired.
Q. What is your title now?
A. Brigadier General, retired.
Q. I wish you would state what experience you have had, or what investigation or study you have made in matters regarding hydraulic measurements, and the same in regard to your knowledge of the conditions of the Great Lakes, and the waters connecting, and other waters in the United States; in a general way, the scope of your experience in these lines.
Witness: As an engineer?
Mr. Reid: Yes.
A. I graduated from West Point in 1864, and served in the corps of engineers of the army until I retired under operation of law in 1906. After a short service in the Civil War, I was engaged on the Pacific Coast on fortifications, and surveys until 1868. From 1868 to 1871 I was stationed at the Engineer's School of Application at Willetts Point, where, among other things, were more or less studies of hydraulics and topography. From 1871 to 1878 I was instructor of Practical Military Engineering at West Point Military Academy, where I performed the duties of architect of the more important structures there and in charge of water works. From 1878 to 1886 I was stationed at St. Louis in charge of the River and Harbor District, with headquarters at that place, including the Mississippi River. From 1884 to 1894 I was a member of the Missouri River Commission, and from 1888 to 1894 I was a

member of the Mississippi River Commission, and later on I was President of that Commission, from 1902 to 1905, I think, or perhaps from 1903 to 1906, yes, that was it. From 1886 to 1889 I was stationed at Galveston, Texas, having charge of the rivers and harbors of the Texas Coast. From 1889 to 1893, I was here in Washington as Aide-de-Camp to President Harrison, and had charge of the public buildings and grounds here, and was a member of the Lighthouse Board. From 1893 to 1898 I was in command of the Military Academy at West Point. I served in Porto Rico and Cuba during the Spanish War of 1898. In 1899 I was a member of the Isthmian Canal Commission, appointed to investigate all routes for the Canal across the Isthmus. I served on that Commission until 1901. From 1901 to 1905 I was stationed at Chicago, having charge of the rivers and harbors in that district, of the local works there, and was also division engineer of the Northwest division, which included the Great Lakes system as far east as Erie, Pennsylvania. During that time I was Chairman of a Board of Engineers appointed to make surveys and estimates for a waterway 14 feet deep from Chicago to St. Louis. From 1905 to 1906, I was again a member of the Isthmian Canal Commission, and in 1905 I was appointed on the International Waterways Commission. I am still Chairman of the American Section of that Commission. That Commission has made a report on the Chicago Drainage Canal. I believe that covers my record.

Q. State what the scope of your duties was in regard to the Great Lakes and bodies of water connecting, or the connecting waters; what you had to do, your observations, studies and just what came under your direction and observation.

A. I had general supervision of all the districts in the region I speak of, the construction districts, and in connection therewith it was necessary for me to know more or less about the needs of navigation in order to fix on the dimensions of channels and the propriety or necessity of their construction.

Q. In that matter, it would come under part of your duties to know about the diversion of water from other bodies of water, the decrease or increase of water levels, hydraulic measurements and things of that nature?

A. Yes. I had to examine into these questions.

Q. State in a general way what you had to do or what came within your knowledge in these capacities in regard to navigation and commerce on the Great Lakes.

A. Well, I had to become familiar with the size of vessels employed, the amount of commerce that existed; in other words, the requirements of navigation, and I made some original studies in connection with the Illinois River, ascertaining what could be done in that river with the volume of water such as was being diverted down that river, what use could be made of it for navigation purposes.

Q. State what came under your observation with regard to vessels and the loads they were to carry and the different methods of handling these loads and vessels.

A. I visited the ports where the great freight carriers loaded and unloaded and had conversations with the managers of that business, and ascertained from them their needs and their prospects. I have overhauled the official list of vessels published by the United States Government to ascertain how many vessels of deep draft were navigating the Great Lakes, and what their freight tonnage was.

Q. Did you become acquainted with the drafts that the different vessels draw, and the loads, and things of that nature?

A. Yes, sir.

Q. Leaving that for a moment, I want to ask you if you know of the local conditions in the vicinity of Chicago, as in the Chicago and Calumet Rivers, and in and about where the Chicago Drainage Canal is located? Do you know what effect the diversion of say 4,000, 5,000, 10,000, or 14,000 cubic feet of water per second would have on Lake Michigan, if diverted into the Drainage Canal?

A. I think I do, yes.

Q. What would it be on Lake Michigan?

A. I have in mind—

Mr. Reid: As to whether it would lower it, or what effect it would have.

A. It would be lowered.

Q. State the effect it would have on Lake Michigan or the other Great Lakes.

Witness: For a given amount?

Mr. Reid: No, just generally.

A. It would lower the whole system of Great Lakes below the St. Marys River.

Q. That would include all the bays, inlets and harbors connected with the Great Lakes?

A. Yes, everything.

Q. Could you state what effect the diversion of 4,000 cubic

feet per second out of Lake Michigan into the Drainage Canal would have on Lake Michigan?

Mr. Williams: The question is objected to. I have no objection to your asking for his opinion, but object to your asking for absolute fact, unless the proofs or data from which he speaks are submitted.

A. The figures which I have in mind are the amount that would be lowered by 10,000 cubic feet per second. That is about 52/100 of a foot, say 6¼ inches.

Q. Would the same proportion hold good as to 4,000, 5,000, 6,000, or any other number of feet?

A. Yes.

Q. Could 4,000 cubic feet per second be diverted at Chicago without lowering Lake Michigan?

A. No.

Q. What do you understand is the meaning of the term "lowered"?

A. I mean relative lowering. Of course, the level of that lake is oscillating, due to winds, varying barometric pressure, varying rain fall and evaporation. When I say lowering, I mean that it is lower than it would be without that diversion.

Q. It is possible that the lake may really be higher in feet and inches, and still be lower in your definition?

A. Yes.

Q. Is it possible to divert 4,000 cubic feet per second, and have the outflow in the St. Clair River go on forever undiminished?

A. No, sir.

Q. What is the net supply, as you understand it, in regard to bodies of water?

Witness: What is meant by that expression?

Mr. Reid: Yes.

A. To my mind it means the quantity of rain fall diminished by the amount of evaporation.

Q. Is that a certain or tangible thing?

A. Yes.

Q. Are the rain fall, evaporation, absorption, run-off in the St. Marys River increased or decreased by the diversions at Chicago?

A. Not at all.

Q. If Lakes Huron and Michigan are lowered in a known amount and Lake Erie in a known amount, what will be the lowering in the Detroit River, Lake St. Clair, and the St. Clair River?

A. I am not prepared to answer that question.

Q. Could you give us the lowering of Lake Erie and Lake Ontario, with a diversion of 10,000 cubic feet per second in Chicago?

A. If you will allow me to refer to memorandum. I do not carry these numbers very well in mind. (No objection being interposed, witness was permitted to refer to the memorandum.) For Lake Erie about 45/100 of a foot; for Lake Ontario, about 35/100.

Q. If a certain quantity of water is diverted in the Drainage Canal, how much will the flow of the Niagara and St. Lawrence Rivers be diminished by that diversion?

A. By that exact amount.

Q. In your experience you have had occasion to reckon upon and take into consideration evaporation in regard to the effect it might have on bodies of water, have you not?

A. Yes, sir.

Q. I will ask you if in your judgment the evaporation should be considered in an attempt to detect the presence or absence of the effect already produced in the lakes by the diversions made at Chicago since 1900?

Mr. Williams: Question objected to on the ground that it is leading.

Mr. Reid (continuing): And can you give us your opinion as to how exact any data of this kind is?

Mr. Williams: The objection stands to the whole question as completed.

A. Why, of course, evaporation is an exceedingly important consideration, but you mean, I suppose, whether I think that the result of direct observation on evaporation, the amount of evaporation, is of use?

Mr. Reid: Whether that is certain or accurate enough to take into consideration.

Witness: No, nobody knows what the volume or amount of water evaporated is.

Q. Have you any information as to how much the error might be in regard to this data?

A. No; it might be very great; it might be 20 per cent., more or less. Nobody knows even approximately what that evaporation would be.

Q. In regard to precipitation and its effect in the same way, that is not well determined, is it?

A. The rain fall observations are made at isolated points over this large area. They can not be made on the areas occu-

pied by the lakes themselves. The average taken over that entire basin may be a fair average or may not.

Q. I want to ask you with regard to the boats. Can you give us the figures as to how many boats plying between Lake Superior and the lower lakes or the lakes below Superior are capable of loading to 19 feet?

A. I can give you these figures with close approximation, and I can tell you how I obtain it. I went over the official list of merchant vessels published by the government for 1906, took out all the vessels that had a depth sufficient to enable them to load to that draft. I then went to the Lake Carriers' Association and obtained from them the list of vessels that had been added during the season of 1906, and which would not appear in that list. That gives me the vessels for 1907, which is what I have here.

Mr. Williams: Before the witness answers further, in view of what he has already said as to his source of information, I object on the ground that it is not the best evidence on the subject matter upon which the witness is being interrogated, as the reports referred to by him and the persons communicating to him the information should be produced.

Witness (continuing): Four hundred and eighty-three.

Q. With regard to 20 feet?

Mr. Williams: Please note the same objection.

A. Four hundred and thirty-six.

Q. Twenty-one feet?

Mr. Williams: Same objection.

A. Three hundred and ninety-four.

Q. Can you give us the figures on how many tons of freight are carried by all boats capable of loading to 19 feet, traversing the routes as I have before indicated?

Mr. Williams: Same objection.

A. The percentage of freight in such vessels is about 70 per cent. of the total freight carried. In 1907 the total freight which passed through Detroit River was 71,226,895 tons, from which it is computed that about 50,000,000 tons were carried in boats drawing 19 feet or more in that year.

Q. What proportion of this freight is carried under conditions of maximum loads as limited by draft in the lower levels of the lakes, of the Sault or St. Marys River, and in the lower lakes and rivers to Chicago or Buffalo, or other lake or river ports?

Mr. Williams: Same objection.

A. 36,000,000 tons.

Q. Can you give us the proportion of what is known as up-bound freight and the other way?

Mr. Williams: Same objection.

A. The freight bound East is about 80 per cent. of the total. Up-bound 20 per cent.

Q. Which is up-bound?

A. The west-bound. The percentages are:

1904, 76 per cent.

1905, 83 per cent.

1906, 80 per cent.

1907, 78 per cent., about 80 per cent.

Q. You gave us some figures in regard to the tons of freight carried by boats capable of loading to 19 feet, I want to ask you the figures regarding boats capable of loading to 20 feet.

Mr. Williams: I make the same objection.

A. About 29,000,000 tons.

Q. Can you give us the way this freight is carried by boats loading to 20 feet, the proportion, through the routes indicated for the 19 foot boats?

Mr. Williams: Same objection.

A. When I say the total freight, I speak of all the freight.

Q. For all the boats?

A. Yes.

Q. When a large freighter is loaded in Lake Superior for Lake Erie ports or Lake Michigan ports, what determines the depth to which she is loaded?

A. The depth of water in the locks and the Sault and channels below. The depth of water on the mitre sill on the Poe lock is 19 feet usually. Nineteen feet is the depth at low water. They keep in telegraphic communication at the Sault and when a boat is loading at the west end of Lake Superior, they will load her down deeper than 19 feet if they find they can do so with safety.

Q. You mean by that the limiting depth?

A. You may say it does not go below 19 feet; it sometimes goes above 19.

Q. You mean that is the limiting depth?

A. That is what fixes the draft to which they can load these ships, the freight carriers.

Q. By mitre sill, do you mean the highest point?

A. The highest point of the lock, yes.

Q. What about the lower level? How do you consider that in saying that the mitre sill is the one that controls?

A. I mean by 19 feet over the mitre sill, the least depth to be found in the lock.

Q. The lock or any body of water changes and fluctuates, does it not, on account of storms and other causes?

A. Yes.

Q. Do you consider that the loss of depth of two, four or six inches affects the navigation any way?

Mr. Williams: I object to the question as leading, incompetent and also on the ground that it calls for a conclusion and not for a fact.

A. I think it does.

Q. Is the loss more serious under these conditions than it would be otherwise?

Mr. Williams: Objected to on the ground that it is leading and calling for comparison.

A. I do not think it is a very important consideration. If it affects it in any way at all, I think it would make it a little more serious.

Q. Do you know the dimensions of the present largest freight carriers of the lakes, traversing the water below Lake Superior?

A. There are three new boats.

Q. How much freight in tons is carried on these vessels on each inch of draft between 19 and 21 feet?

Mr. Williams: Objected to on the ground that it calls for information which witness does not purport to give as from his own personal knowledge.

A. There are three new boats, the William M. Mills, William B. Kerr and the Le Grande De Graff. They are all the same size, and are the largest freight carriers now on the Great Lakes. They are each 607 feet long over all, beam 60 feet; depth 32 feet. Each has a gross tonnage of 7,970 and a carrying capacity of 13,000 tons. About 85 tons is carried in one of these vessels on each inch of draft between 19 and 21 feet.

Q. For a boat of less than 19 feet, would the same proportion hold good?

A. Yes.

Cross-Examination by Mr. Williams.

Q. All the information that you have given with reference to the vessels navigating the Great Lakes, their tonnage, and their dimensions, has been based on information obtained by

you from other sources, partly from official records and partly from records of private concerns, associations, etc.?

A. Yes, sir.

Q. And no part of this evidence that you have given with reference to these matters is based on your own personal knowledge?

A. No, sir.

Q. You spoke of the fact that Lake Michigan was subject to oscillations on the surface of the lake, do you know the extent of these oscillations?

A. Yes, I can give you that by reading a couple of paragraphs in this report by the International Waterways Commission, of which I am a member, or I can refer you to them. Shall I read them?

Mr. Williams: So much as is in answer to my question. I asked to what extent is the surface of Lake Michigan subject to oscillations.

Gen. Ernst: It will oscillate two or three feet in 15 minutes sometimes.

Q. And these oscillations are caused by weather conditions largely and barometric pressure?

A. The oscillation that I just spoke of is the barometric pressure. That is what is called a seiche.

Q. You stated, General, that in case of a diversion of 10,000 cubic feet of water per second from Lake Michigan, the level of the lake would be lowered to the extent of 52/100 of a foot, and I also understood you to say that the withdrawal of any larger or smaller amount would cause a corresponding variation in the level of the lake?

A. Yes.

Q. Is that true precisely or only approximately?

A. I think you may say it is true absolutely. The curve of relation between the discharge and the level is a straight line, plotted as carefully as it can be plotted.

Q. Would you say, for instance, if 100,000 cubic feet of water was diverted from Lake Michigan, the variation in the lake level would be just ten times as great as the variation caused by a diversion of 10,000 cubic feet per second?

A. I think approximately that is true.

Mr. Williams: That is the reason I asked you before whether it is exactly true or approximately true.

Witness: It is approximately true. It is within the limits of our observations.

Q. Does it make any difference what the stage of the water

in Lake Michigan is as to what effect a diversion of 10,000 cubic feet or any definite quantity of water from the lake at Chicago would have on the lake level?

A. Yes.

Q. In your opinion, the effect testified to by you of 52/100 of a foot by the diversion of 10,000 cubic feet is assuming a certain definite stage of the water?

A. The average stage.

Q. Averaged for what periods?

A. The periods covered by the records, what is known as the mean stage of the lake.

Q. And these records include what year last?

A. From 1860 down to date.

Q. Including the year 1908?

A. We will say 1907, or perhaps 1906. They were made a couple of years ago. The mean average stage from 1860 to 1906.

Q. That is 47 years?

A. Yes.

Q. Your estimates are based on what data, General?

A. Upon the reports of the Lake Survey.

Q. Are they the same reports as those used as a basis for the preparation of the plates that have been referred to in the testimony heretofore given by Mr. Noble?

A. I think there has been some revision since those reports that have been used in the preparation of those plates, but I am not positive.

Q. In the making of the estimates and the forming of the conclusions of which you testify, did you obtain any information which was not available and used in the preparation of these plates?

A. No.

Q. Do you know of any other record of discharges and gauging that afford sufficient accuracy to enable you to make any computation that would be reliable, and to which you would want to testify as to the effect of diversions?

A. I rely entirely upon the observations on the lakes in the opinions that I have given, absolutely.

Q. And you consider them the best in existence?

A. Yes, sir.

Q. What percentage of accuracy would you ascribe to the records of precipitation in the area covered by the water shed of the Great Lakes?

A. I do not know. That may be about 20 per cent. I do not know anything about that and nobody else does.

Q. Do you consider the records of discharges which you have used as a basis for your computation as absolutely correct?

A. Well, when you say "absolutely," no. It is impossible to measure water with absolute precision. There are very close approximations.

Q. What percentage of accuracy would you ascribe to those computations?

A. I suppose within 5 per cent.

Q. Assuming that Lake Michigan and Lake Huron were lowered in a definite amount, say one foot, by reason of the diversion occurring at or near Chicago, what effect would such a lowering have upon the depth of the St. Clair River as compared with the lowering in Lakes Michigan and Huron?

A. Approximately, I think, it would lower a foot at its head, and a somewhat less amount at its foot.

Q. Have you memorandum or data or could you make a computation to indicate the difference in the effect at the foot of the St. Clair River as compared with its head, assuming a loss of a foot in the Lakes Michigan and Huron?

A. It has been worked out. I think I could find it for you. I haven't it in my mind just now.

Q. Could you give the percentage?

A. Not now.

Q. How much work would it involve?

A. I could not tell you. I would have to look that up.

Q. Have you an opinion and can you state approximately what percentage of the effect perceptible in Lakes Michigan and Huron due to diversion at or near Chicago would be observable in Lake St. Clair?

A. That is the same question. I am not prepared to give you the exact relations.

Q. Would Lake St. Clair be approximately the same level as the foot of St. Clair River?

A. Yes.

Q. The entire lake?

A. Yes.

Q. And what would you say as to the Detroit River?

A. The head of the Detroit River is the same level of Lake St. Clair.

Q. And the foot of it?

A. There would be a slight depreciation of the effect.

Q. For Lake Erie you gave us figures on the basis of 10,000 cubic feet, now for Lake Michigan would the same proportion apply there?

A. Yes.

Q. What would you say as to the effect observable in Niagara River?

A. There would be a diminution there again.

Q. As you approach Lake Ontario there would be a diminution of the effect observable?

A. Yes.

Q. And Lake Ontario would bear the same relation upon the hypothesis of 10,000 cubic foot diversion?

A. Yes.

Q. And the St. Lawrence River, I take it that at the head of the river the effect would be practically the same as Lake Ontario?

A. In the lowering of the level, yes.

Q. And that effect depreciates down to the Gulf?

A. No, that does not follow. Then comes the difficulty of cross-sections and slopes.

Q. Except as to the narrowing effect of the river in some cases, the general tendency would be to depreciate in effect until it dropped down to the Gulf, if you did not take into consideration those parts of the river that had a great variation of slope?

A. If you can omit those, but you can not do that.

Q. I take it that by the time you have reached the Gulf of St. Lawrence, the effect of the diversion is scarcely perceptible?

A. When you get down into tidal water, I do not know that it is.

Q. In order to make an accurate determination at any given time of the effect of any definite diversion from a lake, say Lake Michigan at Chicago, I mean the effect on the lake level, would it not be necessary at that particular time to take into consideration the evaporation and rain fall?

A. No.

Q. You could not take them into consideration?

A. No; not directly. Of course the whole question is dependent on them absolutely, but their relative value is what we want. We can get that by discharge measures.

Q. Suppose you wanted to know the effect today on the level of Lake Michigan of the diversion of a definite amount of water, not the ultimate effect or general effect, or the aver-

age effect, but what is the effect today on the lake level, would it not be necessary to take into consideration the rain fall and evaporation?

A. No, except as to their relative values. If you should take absolute values of these, you might get results which would be preposterous.

Q. Is it a fact or is it not that the reason you will not take them into consideration in arriving at a conclusion as to the actual effect at a given time, is that the information concerning them is so indefinite and unreliable that you could not with safety testify?

A. That is a reason which is certainly conclusive, but if you ask me whether any man can go out and ascertain the change of level in Lake Michigan today without any observations before or after, I would say he can not do it. Let me explain that subject a little more fully. I would like to read a couple of paragraphs from this report.

Mr. Williams: Would you like to read them in as a part of your testimony?

Witness: Yes.

Mr. Williams: This is not in response to a special question, but is an additional statement by witness in explanation of the difficulty of ascertaining the effect of diversions upon the level of the lake by any brief or limited observations.

General Ernst requests the privilege of reading the two paragraphs Nos. 22 and 23 of the Report of the International Waterways Commission of the Chicago Drainage Canal. Counsel for the respondent signifies his willingness to have the paragraphs read. Counsel for the petitioner requests the witness to abstain from reading the paragraphs, unless counsel for the respondent makes the special request therefore and adopts it as part of his cross-examination.

Q. I will ask you whether or not you have heretofore made any statement bearing upon the subject of this inquiry which you would like to incorporate in this record as an additional explanation of the subject matter about which you have testified?

A. I would like to explain what I mean by the oscillations of the Great Lakes.

Mr. Williams: I will ask you to make that explanation.

Witness, reading from the report of the Chicago Drainage Canal by the International Waterways Commission, paragraphs 22 and 23, as follows:—

"22. Variations in the level of the lakes' surface, due to

winds and to change of barometric pressure, are frequent and irregular and at times violent. Variations of more than six inches are very common, often occurring hourly for many hours in succession, while variations of two or 3 feet within an hour are not uncommon. Besides these irregular variations there is a regular annual variation due to difference in rain fall, evaporation, and run-off, the water level being highest in mid-summer and lowest in mid-winter. The levels are affected also by the greater or less severity of the winter and the consequent greater or less decrease in the discharging capacity of the outlets by ice. In order to study the annual oscillations it is necessary to eliminate the irregular oscillations, and that is accomplished by using the average levels for a month. Using the monthly mean levels it is found that the regular fluctuation in Lake Huron-Michigan usually does not exceed two feet in any one year, but in a long series of years there is a great difference in the height to which high water will rise. The highest high water (monthly mean) recorded for that lake was in June, 1886, and the lowest high water in June, 1896, the difference between the two being over 3½ feet. The first is what navigators of the Great Lakes call a high-water year and the second a low-water year.

23. It is evident that the average level of the lake may be lowered considerably without the change becoming immediately apparent, and that fact has been used as an argument to prove that the lowering caused by the Chicago Drainage Canal is of no consequence to those interested in navigation. Since they can not see it they will not know it and will not feel it. The argument is fallacious. It is true that they can not see it immediately, but they will soon feel it and will know it through the most costly means of acquiring knowledge—the injury to their material interests. The oscillations will remain the same as before, but low water will fall lower and high water will rise less high. The average draft of vessels must be diminished by the amount that the average level is lowered unless the depth be restored by remedial works."

Q. These paragraphs were written by you?

A. Yes.

Q. Is there an expression of opinion there contrary to the opinion expressed by you at a previous time?

A. No.

Q. Were you a member of the Board of Engineers which reported on the proposed waterway from Lockport to St. Louis?

A. Yes.
Q. You were Chairman of that Board, were you not?
A. Yes.
Q. Did not the Board, of which you were Chairman, state in its report that navigators were not likely to find out that a lowering of six inches had occurred in Lakes Michigan and Huron?
A. No; here is what I said, or the Board said. I may say that I wrote both these reports:
"A permanent average lowering of six inches in the lake's level therefore is not easily observable, and will probably not be noticed by navigators. Nevertheless, the effect is real and important." Now a great deal of weight has been put on that language "probably not be noticed by navigators." You may undermine the foundations of a man's house and he will not notice it, and in that sense the navigators do not notice that their foundations are being undermined. There is nothing inconsistent between this statement and that statement, not a bit.

CURTIS McDONALD TOWNSEND, a witness called on behalf of the complainant, having been first duly cautioned and sworn, testified as follows:

Direct Examination by Mr. Reid.

Q. What is your name?
A. Curtis McDonald Townsend.
Q. Where do you live?
A. Detroit, Michigan.
Q. What is your profession?
A. I am army engineer; Lieutenant Colonel of engineers.
Q. How long have you been employed in that capacity?
A. Since 1879.
Q. What has your experience been?
A. Well, I have been very generally employed in the improvement of rivers and harbors of the United States.
Q. State in a general way the geographical locations that you have been in.
A. At the present time?
Q. No, in your experience.
A. Oh, my experience; well, as assistant I had work on the rivers in the vicinity of Baltimore, of Petersburg, Vir-

ginia, and of Charleston, West Virginia. I then was an assistant to the engineer commissioner in the District of Columbia. Afterwards was Quarter Master at Willets Point in charge there of constructing some houses. I afterwards was assistant in charge of the construction of the tunnel for supplying the City of Washington with water. I then was in charge of the third district on the Mississippi River. Then I had charge of the Grand Rapids district, and the rivers and harbors on the east shore of Lake Michigan. Then the Rock Island District, in charge of the upper Mississippi River from St. Paul to St. Louis, or to the mouth of the Missouri. Then was in charge of the harbor of Manila in the Philippines. Then returned to this country and had charge of the rivers and harbors in the Cleveland district; the harbors on Lake Erie from Toledo to Conneaut, and from there was placed in charge of the Detroit district, which has charge of the waters connecting the Great Lakes and certain harbors in Michigan, on Lake Huron and Lake Erie.

Q. How many years have you been on the Great Lakes altogether in this line of work?

A. About five years.

Q. Now state of what your work consisted.

A. The improvement of harbors, which would consist at certain times of dredging those harbors to certain depths; at other places including building breakwaters, which would protect the entrance to certain streams.

Q. Particularize a little more.

A. Well, for instance when improving the harbor at Toledo, there the work consisted simply of dredging a channel in the Maumee River from Toledo to Lake Erie. In improving the harbor of Conneaut, the work there consisted of dredging into the river at that place and also constructing breakwaters that would protect this dredged channel. At Cleveland the work consisted of building a breakwater and of dredging a harbor behind it. The work I am now employed upon consists in deepening the channels which are connecting the Great Lakes and building a lock at the Sault Ste. Marie. That is the principal work.

Q. What do you do in accomplishing this result in regard to measuring and obtaining knowledge of the water, and things of that kind?

A. The first thing that is necessary to do is to make a survey and determine the depth of water that you have in your channel; then to determine the material of which the

bottom is composed. Then you have to make a contract for either excavating the sand or rock.

Q. Now in regard to the level of the water there, does this work which you do necessarily take into consideration the levels?

A. That is the first necessary thing in a survey is to know the level of the water, so that you can determine what your depths are.

Q. In doing this, you not only know the level of the water in the particular places, but in connecting bodies of water?

A. We have to know the levels of water at the point where we are doing our work, and its relation to the levels of the connecting lake.

Q. You actually had those things under consideration when you were doing this work?

A. Yes.

Q. And that is part of the work?

A. We have to arrange our work on a certain datum plane.

Q. I show you Complainant's Exhibit No. 5 of date April 19, 1909, and ask you to mark the limits of the district in which you are now in charge; and when you mark it state where the marks are being placed.
of the district.

A. The head of St. Mary's River marks the northern limit

Q. Mark that No. 1.

A. That is Number 1. The next limit of the division are the Straights of Mackinaw between Lake Michigan and Lake Huron.

Q. Mark that No. 2.

A. Marked No. 2. The district then includes Lake Huron and St. Clair River, Lake St. Clair, the Detroit River and the harbor of Monroe, which is the southern limit of the district.

Q. Mark that No. 3.

A. That is No. 3.

Q. Have you named all the geographical names of the bodies of water within that district?

A. No. There have been improved in this district in the upper St. Mary's River, three localities. Then there have been constructed some locks, the Whitsall and Poe locks at the Sault Ste. Marie. The channel from the Sault Ste. Marie to Mud Lake has been improved and is now under improvement. There have been certain spots between Mud Lake and Detour dredged. Then there has been improved along the shore of Lake Huron the harbor of Cheboygan, Alpena, Saginaw

River; a breakwater at Harbor Beach, Sebewaing. Then the St. Clair River has been improved in sections; the Black River, the Pine River, Bell River. Then Lake St. Clair has been dredged practically across the lake. Clinton River emptying into Lake St. Clair has been improved, and the Detroit River has been improved particularly in the vicinity of the Limekiln Crossing. Then the furtherest southern work of the district is the harbor of Monroe.

Q. Now in regard to Lake Huron, was there work done at the foot of Lake Huron?

A. Yes, a channel has been excavated at the entrance to St. Clair River at the foot of Lake Huron.

Q. You stated in a general way the improvements and the places that have been improved in your district. Now state the fact as to whether or not there is practical navigation going on in your district?

A. Yes, sir, there is a very considerable navigation going on in the district.

Q. Could you give us in a general way of what that navigation consists?

A. Well, during the year 1907, which is the maximum, there was in the vicinity of fifty eight million tons of freight passed through St. Mary's River; and over sixty million tons of freight passed through the Detroit River; also through the St. Clair River.

Q. Have you observed the vessels that carry the freight through your district, as to their method of loading?

A. Yes, I observed the depths to which they have loaded.

Q. State to what depths they load.

A. They load to as great depth as we will allow them to load.

Q. What has that been?

A. Well, the last year it ran from 19 to 20 feet.

Q. What limits the nineteen or twenty feet?

A. The depth that we have on the floor of the Poe Lock is now our limiting depth. And we have a second limiting depth at Bar Point, which is at the end of the Detroit River; is the entrance to Lake Erie. The third limiting depth would be at Ballard's Reef, a crossing which is just a little further up in the Detroit River.

Mr. Williams: Q. Where is that Ballard's Reef?

A. That is several miles up the Detroit River, from the mouth.

Q. Bar Harbor is at the mouth?

A. Bar Point is at the mouth. That is in Lake Erie.

Mr. Randolph: Q. Is Bar Point the second limiting point?

A. Bar Point is the second limiting depth. Of course I will say the second limiting, it will be the same as the first limiting point.

Mr. Reid: Q. What information do you give the lake carriers?

A. There is published at the Sault Ste. Marie the depth that we allow in the Poe Lock; that is published, given to the public.

Q. Assuming that 10,000 cubic feet of water is drawn from Lake Michigan at Chicago, and the drawing of that 10,000 cubic feet per second lowered the lake, the level, say five inches. Would that have any effect on the level in your district?

Mr. Williams: Just a moment, before that question is answered: I want the record to show that I object to the question, first on the ground that it is not intelligible and second on the ground that the witness has not shown himself to be qualified to testify on the point of the effect of diversions at different points?

A. Yes, it would.

Q. Will you give us to what amount?

Mr. Williams: I object to the question on the ground that it is not intelligible; and second, on the ground that the witness has not shown himself to be qualified to testify on the point of the effect of diversions at different points.

A. I could not tell the exact amount except by hearsay.

Q. Assuming that there would be a loss in the level of five inches in your district, state what effect it would have in your district at the particular points.

Mr. Williams: Objected to first on the ground it assumes a condition not shown; and in the second place that it is incompetent, irrelevant and immaterial, because this suit has nothing to do with the diversion of 10,000 cubic feet of water per second.

Mr. Reid: Q. Assume that 4,000 instead of 10,000 cubic feet, as in the other question, would lower the level of Lake Michigan two and a half inches, would that affect the level of the water in your district?

A. It would.

Mr. Williams: I object to the question on the ground it is improper; on the ground it contains an assumption; on the ground it has no meaning whatever.

Mr. Reid: Q. Assuming that the water in your district were lowered two and a half inches, would it affect the practical navigation therein?

Mr. Williams: I object to that question on the ground the witness has not shown himself to be qualified to testify upon questions of navigation.

A. It would.

Q. What effect would the loss of two and a half inches of water in your district have on the different places in your district?

A. It would have a lowering effect; while not necessarily of two and a half inches at these localities, it still would have an appreciable lowering effect at each of the localities that I have alluded to.

Q. Where would the loss of two and a half inches make any difference in your district?

A. It would make a difference in the district to all harbors on Lake Huron; not exactly to two and a half inches.

Q. What do you consider the critical points in your district for navigation?

A. The critical points for large vessels are Poe Lock and the foot of Detroit River.

Q. What effect would the loss of two and a half inches of water in the level have on these particular places?

Mr. Williams: I object to that question on the ground that it assumes the lowering of a definite amount at these particular points, and there is no testimony yet in the record—the witness testifies he can only testify as to hearsay as to the effect of a lowering of two and a half inches at Chicago on these different points; therefore I object to the question as an assumption.

A. That would require a mathematical computation to determine, as the level of Lake Erie does not fall exactly in co-ordinance with the level of Lake Huron, nor does the level below the lock at the Sault exactly co-incide with the level of Lake Huron.

Mr. Reid: Q. What effect would it have on the amount of water that would be in these particular places that you name, considering the vessels that go through them, having in mind the fact that you people give to the carriers on the lakes the depths to which they can load?

Question objected to by counsel for the defendant, on the ground it is incompetent, irrelevant, immaterial, and calls for a conclusion and not a fact; and on the ground

that it is based upon an assumption that has not been shown to exist.

A. Well, it would lower those depths.

Q. At these critical points state the fact in regard to the vessels, if it is a fact, loading right down to the very limit that you people allow them.

A. These vessels load to the limit and sometimes even beyond the limit. I have to give instructions to allow no vessel to enter the Poe Lock that draws more than the orders admit for that date.

Q. Now, if you had an inch or two inches or two inches and a half less water in those particular places, they would have to load that much lighter would they not?

A. They would load just that much lighter. If they had two inches less, that would be the—

Q. Would one inch make any difference whatever?

A. Every inch, then, they would make use of.

Q. Do you know the number of tons those big vessels load to the inch beyond a certain amount?

A. They load from 75 tons to 100 tons to the inch; that is when they are loaded; that is when you are between 18 and 19 feet, or 19 and 20.

Q. The lowering of an inch at Bar Point would have the same results?

A. The lowering at Bar Point would have practically the same results. They utilize that to the utmost limits.

Mr. Reid: That is all.

Witness: Let me state in reference to that that one time it will be the Poe Lock and another time Bar Point where we have conditions—Bar Point is lower than Poe Lock, and other conditions when Poe Lock is lower than Bar Point; but the limiting depth that we have, they will utilize to that extent.

Cross-Examination by Mr. Williams.

Q. Colonel, you speak of a vessel being loaded between 19 and 20 feet to the extent of about from 75 to 100 tons to the inch?

A. Seventy-five to 100 tons to the inch would be about what it was.

Q. Assume that a vessel is loaded to a depth of five feet, and then loaded an additional inch, would that be a different

amount that would be required to lower it an inch, after it had been loaded to 19 feet?

A. Yes, there the effect of the bottom would enter in more.

Q. Sir?

A. Yes, sir, I should say the effect would be—there is a slight curvature at the bottom. These boats are pretty nearly rectangles so that when you get down a little ways they lower about the same; but there is a slight curve to the bottom, and I think in the earlier loading, I should say that there would be a tendency to be a little less amount for—

Q. For each inch?

A. For each inch.

Q. Does that amount of loading necessary to lower the boat one inch increase proportionately all the way down from say 6 feet to 20 feet?

A. No, after you get the boat started, it is pretty nearly a rectangular section, but in the earlier starting of loading, I would not be able to say; in the first place your boat is tilted instead of being a rectangle she is a triangle; I should not know just what would take place, but after she gets well loaded then she is pretty nearly rectangular.

Q. Will you give me the name of any vessel that loads 100 tons to the inch?

A. Well, I should take one of these 605 footers, that would come very close to it. They would be the maximum.

Q. Do you know the name of any of those boats that you refer to?

A. No, I cannot at the present time recall the names of the—

Q. How many of those 605 foot boats are there navigating the Great Lakes in your district now?

A. At the present time there are none; but there are five or six.

Q. What is the depth of the water at the Poe Lock?

A. Poe Lock, the last I heard it was 18 feet 5 inches was the depth allowed in the Poe Lock.

Q. And that was the limit of depth at that time?

A. At this particular time.

Q. What is the average depth at Bar Point?

A. Well, that depends on the stage of Lake Erie, and at the average stage of Lake Erie it would be about a little over 20 feet.

Q. Now what is the average depth, taking the mean level

of the water in Lake Huron and Lake Erie, of Ballard's Reef?

A. Ballard's Reef, that is a little over—about 21 feet at mean levels.

Q. Now you state that there are improvements now in progress on the Detroit River?

A. Yes, sir.

Q. And at Bar Point?

A. There is not in progress at Bar Point, but we contemplate improving Bar Point.

Q. Plans are made for improving Bar Point?

A. For improving Bar Point.

Q. When those plans have been executed and the work contemplated is completed, will the depth of water at Bar Point be increased?

A. We intend to have that 21 feet at extreme low water.

Q. Twenty-one feet at extreme low water. What work is now being done at the Poe Lock?

A. Poe Lock, we are at the present time enlarging the channel entrance to the lock and we are proposing to build a second lock, to increase the depth there.

Q. To what extent will the depth there be increased?

A. To 24½ feet.

Q. When will that improvement be completed?

A. We expect in about five years.

Q. In five years?

A. About five years, hope to complete it.

Q. When do you contemplate, would you say, that the work on the Detroit River at Bar Point will be completed?

A. We will improve the Bar Point reach within the next year.

Q. What effect will the improvement of the Detroit River have upon the level of the Detroit River?

A. I do not know.

Q. What is the natural result of the improvement, does it increase or decrease the slope in the river?

A. It should theoretically increase the slope—decrease the slope.

Q. Decrease the slope?

A. No, let me see a minute: No, it increases the slope over the section of the river not improved.

Q. Over the section not improved?

A. Not improved; decreases it over the section improved.

Q. Will this deepening, in your opinion, provide for an

outlet of a greater amount of water than now flows through the Detroit River?

A. Yes, I think it will provide for a slight increase.

Q. And the supply of water which flows through the Detroit River comes primarily from Lakes Huron and Michigan does it not?

A. Comes from Lakes Huron and Michigan.

Q. And the effect of that improvement will be of itself theoretically at least, to lower the level of Lake Huron?

A. Theoretically, yes.

Q. What do you say practically?

A. Practically I say I don't know, as I am at the present time engaged in trying to determine just that very question.

Q. You can conceive of a situation then where theoretically the withdrawal of water and increase of flow through a channel leading from Lake Huron ought to lower the level, but actually would not?

A. No, I didn't say that. I say that theoretically I think it does but it may not be a practical question of sufficient—

Q. You would want further investigation before you would say actually it did?

A. Actually it did; that is it was of any practical amount.

Q. And the level of Lake Huron is substantially the same as the level of Lake Michigan?

A. Yes.

Q. In other words what affects the level of the water in Lake Huron, to the same degree affects the level of the water in Lake Michigan?

A. Yes.

Q. In making your reports to the commercial interests that navigate the Great Lakes, you report the navigable depths at the critical points?

A. I report particularly the navigable depths at the Sault.

Q. At the Poe Lock?

A. At the Poe Lock.

Q. And that is considered really the critical point?

A. That is at the present time the critical point.

Q. How nearly do you report, and how closely do you report that navigable depth, in inches or fractions?

A. What I report is the safe—what is considered the safe limit of loading for the boat so that she will not get aground in the lock.

Q. Do you report that in inches or in feet?

A. I don't remember whether it is reported in feet and inches, or feet and tenths.

Q. But either in feet and inches or feet and tenths?

A. Either in feet and inches or feet and tenths.

Q. How closely to the actual navigable depth do you report it safe for a vessel to load?

A. I don't know what the exact relation is there.

Q. You prepare the reports yourself?

A. I do not; I instruct my assistant at the Sault to submit these daily reports of what he considers safe for a vessel.

Q. Then the reports you have mentioned that are given to the owners of the vessels are not made or submitted by you?

A. They are submitted at the Sault.

Q. They are not submitted as the result of any specific direction of your own?

A. Except that I specifically direct them to report the safe depths.

Q. But you don't know the proportion of the depth to the safety of loading?

A. No, I do not.

Q. How do you arrive at the displacement per inch of depth in deep vessels?

A. By the area, cross section of your vessel, multiplied by the cubic feet, multiplied by a cubic foot of water.

Q. Multiplied by what?

A. By the weight of a cubic foot of water.

Q. What is the width of these 605 foot vessels?

A. A little over 60 feet.

Q. About 60 isn't it?

A. It is a little over 60.

Q. It is an easy matter to compute in a vessel 605 feet long and 60 feet wide what the displacement is?

A. I think probably 61 feet wide would be nearer the larger ones.

Q. Very well. I suppose you can do it in just a minute, figure the displacement per inch?

Mr. Reid: I object to this; this is no time for calculation, and things of this kind. The Colonel does not have to do it if he does not want to; encumber the record here with a lot of calculations.

The Witness: I should make that about 94 tons.

Mr. Williams: You figure it as a perfect rectangle.

A. I just took it as a perfect rectangle.

Q. Isn't it customary in making those figures to take 90 per cent., by reason of the slopes at the bottom?

A. It may be. I say, my expression is 75 to 100 tons.

Q. You take the net tons of 2,000 pounds instead of the gross tons, 2,240?

A. Yes.

Mr. Wilkerson: Q. How much would it be allowing 2,240 to the ton?

A. Seventy-five tons. I made the statement 75 to 100 tons.

Mr. Wilkerson: Seventy-five is good for our purpose.

Mr. Williams: Q. Are these improvements that you have testified to as being now in progress going on constantly under the direction of the government?

A. They are at the present time.

Mr. Wilkerson: And with the permission of the Secretary of War, I assume.

Mr. Williams: It is a part of the general policy of the government to adjust the condition of the harbors at the critical points to the needs of navigation along the Great Lakes, and this is in pursuance of that general policy?

A. The general policy has been to increase the depths, according to the demands of navigation.

Q. You were asked with reference to a lowering of the lake level at Chicago to the extent of two and a half inches. You do not, of your own knowledge, pretend to give an opinion as to what effect that would have upon these critical points?

A. I do not.

Q. And your answers are all based upon the presumption of two and a half inches at those points?

A. No, they are based on that there will be a reduction at those points, but the amount of that reduction, whether it will be two and a half inches or not, I do not pretend to say.

Q. The improvement of any of the connecting channels lying below Lake Huron will have a tendency, at least theoretically, to lower the levels in the lakes lying to the north?

A. Yes, I think theoretically it would.

Q. The level of Lake Superior would not be influenced by any improvement made below the locks?

A. Not by any improvement made below the falls.

Q. St. Mary's falls. These improvements of the connecting waters lying below Lake Huron have been going on a number of years?

A. Yes, sir.

Q. Have you made any observations or have you familiarized yourself with the result of those improvements?

A. Yes.

Q. Have those improvements tended to lower the level of Lakes Huron and Michigan?

A. I can't find any evidence that they have.

Q. In your opinion as an engineer would you say, without looking into the concrete evidence, whether the tendency would be in that direction?

A. Well, the tendency would be in that direction, but in a very small amount, so small an amount that it is going to be very difficult to determine it. The enlargement of the section is about 5,000 square feet through Lime Kiln Crossing.

Q. And what will be the increasing flow through an enlarged section of that extent?

A. Well, the increased flow immediately in that section will probably be in the vicinity of 14,000 cubic feet, in that particular section; that is if it was just merely that section alone that was being considered.

Q. By the improvement that you have referred to, what would be the increased flow through the St. Clair River?

A. Well, that is just what is very difficult to determine. It will have very much less effect on the St. Clair River than it would on the Detroit River; and it is going to have a comparatively small effect on the Detroit River, because this section is a very short section in a long length of river, and the small change in slope at this one point has got to be spread over the entire river; to make a very serious change.

Re-direct Examination by Mr. Reid.

Q. These measurements at the Poe Lock are made in your department, under your direction are they not?

A. There are no measurments at the Poe—what do you mean, of the depth at the Poe Lock?

Q. Yes.

A. Yes, they are made by my assistants at the Lock.

Mr. Reid: I think that is all.

Mr. Wilkerson: Q. I want to ask you a further question about this Livingston cut: Do I understand that it is proposed to compensate the increased cut at one place, by filling in at another? What is the fact about that?

A. I don't remember having testified anything about the Livingston cut.

Mr. Williams: We have not heard about the Livingston cut before.

Mr. Wilkerson: We understood you were referring to the Livingston cut.

Mr. Reid: What section was that you were referring to?

A. I was referring to the existing section that has been increased; the existing Lime Kiln Crossing extending about 5,000 square feet, but I can find no evidence of its having lowered either Lake St. Clair or Lake Michigan.

Mr. Wilkerson: Q. Has there been any filling in there?

A. We recently built a coffer dam that has filled in very much more than we have excavated.

Q. So that in a sense it would compensate what is taken out in the other way?

A. That will more than compensate for all we have taken out.

Q. In the course of cross-examination, in response to some questions as to the effect of these improvements upon the level of the lakes, you said that theoretically it would have some effect. By that do you mean that if you go ahead and do what you propose to do and the loss would remain constant, that will be the result?

Mr. Williams: I object to the question as a statement by counsel of what the witness means; and I prefer to have the witness state what he means.

Mr. Wilkerson: Q. That is what you mean?

A. I said theoretically it might lower, but that practically I had not seen any effect of its lowering.

Q. Well, what do you mean by theoretically?

A. Well, there are certain results of theory that are obscured by the general things we see in nature. You can say theoretically a thing will be done, and you will find practically that the differences are so slight that they are obscured, and that practically you do not see any effect from it, that is what I mean.

Q. What is it that limits the size of vessels that can be used on the lakes?

A. The draft.

Q. And what is there in connection with either these channels about which you have been testifying, or with reference to harbors about which you have been testifying, which make

it impossible, if that is the fact, to use on Lake Michigan and Lake Huron an Ocean steamer?

Mr. Williams: I object to the question on the ground it is immaterial, and on the ground that it assumes a condition.

Mr. Wilkerson: I do not make myself clear. I want to find out what relation the depth of these channels and the harbors has to the size of the vessels that can be used?

A. Why, they are simply building vessels just as large as we have channels for them.

Q. And are these vessels much larger or much smaller than the vessels which are used, for instance, on the ocean?

A. They are very much smaller. A great many vessels on the ocean are very much larger. A great many other vessels on the ocean are smaller.

Q. I mean as compared with the largest vessels that are used?

A. The largest vessels on the ocean are very much larger than the largest vessels on the lake.

Q. What would be necessary to do to use large ocean vessels on Lake Huron?

A. If you were going to build as deep steamers on the lakes as you have on the ocean, we would have to have channels 35 feet deep.

Q. You would have to deepen these channels and deepen the harbors?

A. Deepen the harbors.

Q. To follow that up, along the line of cross-examination, what practical relation does the size of vessels it is possible to use on the lakes bear to the lowering of these channels and these harbors, even by so small an amount as an inch?

A. If you lower your channel an inch—

Mr. Williams: I want to interpose an objection to the question as calling for a conclusion instead of for facts, on which the court can form its own conclusions.

Mr. Wilkerson: Answer the question.

A. If you lower your channel one inch, you diminish by just that amount the draft which you can utilize in your channel.

Q. And would you say that that same observation would apply to harbors?

A. It would apply to any channel.

Re-cross Examination by Mr. Williams.

Q. That would not hold true however, where the depth of the channel was considerably greater than the draft of the vessel?

A. No, sir. That would only apply to the limiting points of the channel.

Q. The lowering of Lakes Huron and Michigan, you have already testified, would not have any effect upon the amount of water, the depth of the water in the Poe Lock?

A. No, I have not made any such statement as that; I never intended to. The lowering of the water of Lake Michigan will have a very decided effect on the Poe Lock.

Q. What will be the effect on the Poe Lock in the amount of water—

A. It will be in proportion to the lowering of Lake Michigan, but as to the exact amount I could not tell you without a mathematical computation.

Q. Would it be as much as in Lake Michigan?

A. Not quite as much, but it will bear relation to Lake Michigan. That would be a mathematical computation that I have not made.

Q. You have testified that at the Lime Kiln Crossing, when the improvement was being made there, there was a coffer dam built?

A. No, not in the Lime Kiln Crossing, but there is a coffer dam being built on the work we are now constructing.

Q. Did you testify that when the cross section was increased 5,000 square feet that the filling was deposited against it?

A. No—well, that filling was deposited in a sort of a way to compensate in the channel which we are now improving, under the name of the Livingston channel.

Q. And that filling is in the shallow water?

A. That was placed in the shallow water.

Q. Would that have as great an effect on the amount of water flowing through the channel as though it were deposited in the channel proper?

A. No, it would be not as much.

Q. Would you say, Colonel, that the average of the size of vessels navigating the Great Lakes was less than the average size of the vessels navigating the ocean?

A. No, it is very much larger, the average; but the great

vessel that navigates the ocean is very much larger than the greatest vessel that navigates the Great Lakes.

Mr. Wilkerson: That is for the reason you stated.

Witness: The average vessel is a very different thing from the largest vessel.

April 19, 1909; 2:00 p. m.

Court convened pursuant to recess.

Present: As before.

EBEN S. WHEELER, a witness called on behalf of the complainant, was first duly cautioned and sworn, and testified as follows:

Direct Examination by Mr. Wilkerson.

Q. What is your full name, please?
A. Eben S. Wheeler.
Q. Where do you live?
A. In Detroit, Michigan.
Q. What is your present occupation or profession?
A. Civil engineer; United States Assistant Civil Engineer.
Q. In what line of service?
A. I am in the river and harbor improvement office.
Q. At Detroit?
A. At Detroit.
Q. How long have you been connected with that office?
A. That particular office about ten years.
Q. I want to bring out, Mr. Wheeler, your experience as an engineer. Where were you educated?
A. At the University of Michigan. I received the degree of Civil Engineer in '67, and an honorary degree in '97.
Q. Commencing at the time you received your degree of civil engineer, in a general way, and yet being specific as to particular large pieces of work with which you have been connected, I will ask you to state your experience.
A. Well, I was employed by the United States Government on the United States Lake Survey for a number of years, during which time I was engaged in many of the surveys.
Q. What were some of the more important ones?
A. The triangulation of the Great Lakes. I planned most of that and measured its base lines and determined its standards of measurement, and I was also connected with the sur-

veys of various harbors and parts of the shores of Lake Superior. I assisted in some of the earlier stream measurements in the Detroit and St. Clair Rivers, and in the reduction of the same. After I was transferred from the lake survey to the river and harbor office I first went to the Sault, and had charge of the works at Sault Ste. Marie and the superintending of the building of the whole lock under General Poe, I was in local charge. Later I was chief engineer of the Nicaraguan Canal Commission of 1898-9, and since then have been engaged in various works in the river and harbor improvement. While at the Sault I had charge of the stream measurements of the St. Marys River.

Q. In addition to what you have stated is there anything that you can add with reference to your connection with hydraulic measurements of the Great Lakes, tending to give you experience in matters of that kind?

A. I do not know that there is anything further.

Q. You have stated the principal facts—

A. Yes.

Q. —upon which your experience is based. Well, can you state a little more definitely with reference to studies which you may have made of water measurements and determining lake levels, computations with which you have had to do?

A. I discussed the river system of Nicaragua and published the results in the report of the Commission. I have discussed the physics of the Great Lakes, which has appeared from time to time in the chief engineer's reports. I made rather an extensive report of that kind in the report of 1893, and I have made some study in regard to the relative elevations of the different lakes.

Q. You say you made a study of the physics of the Great Lakes; a little more concretely, just what do you mean by that?

A. That includes a study of climatic effects on the lakes, and the relation of the lakes to each other, the characteristics of the drainage basins of the various lakes and it involves a study and analysis of any of the peculiar fluctuations which take place in the levels of the lakes in regard to each other, involves something of the study of the winds and precipitation, humidity, evaporation and allied studies.

Q. You used the term, relation of the lakes to each other. Just what particular relations had you in mind in using that term?

A. One of the most important is the elevation of their surfaces.

Q. And just how much of a study did you make of that, over how long a period of time did your observations extend, and how completely did you discuss that study with the different boards with which you conferred?

A. I occupied several month, perhaps more than half a year, in that special subject. I cannot say that it is very completely discussed yet.

Q. With respect now to the navigation of the Great Lakes, during how long a period have you been making a study of the subject, and having connection with that?

A. Why, since about 1882, when I went to Sault Ste. Marie that became necessary in the building of the lock, and I have a knowledge of the navigation of the lakes, its needs and necessities.

Q. And since the time you commenced that line of work, how continuous has been your observation and study of matters connected with that subject as carried on?

A. I cannot say that it is complete, but I have had the subject generally in mind and have treated it in a general way, hardly exhausted it yet, though—it is a pretty large subject.

Q. Well, compared with others in your line of work who have been studying this subject, what do you say as to the amount of time you have spent, speaking in a comparative way?

A. Well, I should say I have spent more time than most people have on the subject. I do not know that I have got better results, though.

Q. Now, you referred, in enumerating the subjects of which you had made a study, to the term "relative elevation of the lakes" and the "relative elevations of the lake," for the benefit of those of us whom may not be so familiar with the phraseology of this subject, will you define a little more exactly what you mean by that term?

A. Beginning with Lake Superior we find it in general is about 20 feet higher than Lakes Huron and Michigan, but this is not a constant, this varies. The same is true between Lake Huron and Lake Erie. In general that is about eight and one-half feet, the difference between the two lakes. There have been times when it has been more than 10 and sometimes when it has been less than six. We come to Lake Erie and Ontario, and the same variation in elevation is discovered there, and the

causes which lead to these changes in elevation are complex and require some analysis and study to determine them. Perhaps they are not all well determined yet.

Q. What do you mean by the word "elevation" as used in speaking of the lake, the elevation of the lake?

A. Its elevation above sea level, which has been carefully determined at the several lakes.

Q. That means the surface of the lake is so many feet—

A. Above the surface of the sea.

Q. Above the surface of the sea?

A. There would be two planes, that is imaginary plane, the plane of the lake as extended over the ocean, and the two places would be separated by a certain distance.

Q. And that distance you speak of as the elevation of the lake?

A. That is the elevation of the lakes.

Q. Speaking of the elevation of the lake, what is the relation between Lake Michigan and Lake Huron?

A. They are the same. As far as elevation is concerned, they are one, the two make one body of water, one lake. The separation is only for geographical convenience, the separation in name. This would also include Georgian Bay, and those regions on the North of Lake Huron.

Q. In the light of your observations and study, Mr. Wheeler, what do you say would be the effect of the diversion of a given quantity of water, as for example, 4,000 cubic feet per second at Chicago, upon Lake Michigan, upon the elevation of Lake Michigan?

A. One of the results of such a diversion would be ultimately to diminish the flow in the St. Clair River an equal amount. A second result would be to lower the level of Lakes Huron and Michigan, and also of Erie and Ontario, and the connecting rivers.

Q. With reference to the effect of the diversion of this quantity of water, with reference to the determination of the amount of this lowering, have you had occasion recently to make any special inquiry into the subject, any special study of the subject?

A. I have made an examination of some of the points bearing on this question.

Q. With a view to testifying in this case as to the effect of that diversion?

A. Yes, with the purpose of giving more accurate answers than I could from memory.

Q. Supposing that something is done, as for example a diversion of this water at Chicago, the effect of which is to reduce the elevation of the lake at a given point off the shore, say, ten miles, what do you say as to the lowering at that particular point, in its relation to the lowering which would take place at other points in Lake Michigan and Lake Huron and in the harbors and channels?

A. It would lower both lakes an equal amount, both at the upper and lower extremities eventually, of both lakes.

Q. Just what do you mean by the word "lowering" as you used it in this connection?

A. Perhaps I had better refer to my notes.

Q. You may do that.

Mr. Williams: Let the record show that the witness is referring to his notes.

Mr. Wilkerson: I will ask the witness to refer to the notes to refresh his recollection, and to enable him to make a more definite answer.

A. I have said in my notes that lowering means that a definite amount of diversion at Chicago will make the surfaces of Lakes Huron and Michigan a definite amount lower at all times and places than it would have been if the diversion had not taken place. Perhaps I have given too long an answer, the actual elevation of the surfaces of the lakes at any time is the algebraic sum of all the causes which tend to change the elevations. Some of the most important of these causes are rain fall, outflow, evaporation, et cetera. If two causes, producing opposite effects, are operating at the same time then the actual effect produced will be of the same kind as the larger one, and the amount will be the difference between the two causes. For example, a merchant deposits a thousand dollars each week, and checks out fifty dollars each day, his balance is lowered by the amount he takes out, and raised by the amount he deposits, and in this case the deposits are larger than the withdrawals, therefore his balance will be raised by the difference between the two. At the end of the week it will be raised $650, notwithstanding it was lowered $350 by his withdrawals. Similarly, if for the period, we will say, from 1900 to 1908, the rain fall was greater than the outflow, and evaporation, the lake would rise. This appears to have been the case, notwithstanding the outflow for the period was increased by the diversion at Chicago. A cause which tends to lower the lake itself actually does make the lake lower than it

would have been without the cause. I do not know but my answers are a little too long.

Q. That is the sense in which you speak of the lowering of the lake level, you use the word "lower"—

A. Yes.

Q. You mean that it is lower than it would have been if that particular cause had not been present?

A. Yes, I should emphasize that, *it is lower than it would have been without the cause.*

Q. But as you have stated there through the operation of other causes the ultimate effect may be that the elevation is actually higher?

A. Yes.

Q. But through the operation of one cause the real effect of that particular cause has been to lower the level?

A. Yes.

Q. That is to say, to repeat, when you speak of "lower," you do not mean with respect to a fixed mark, but you mean with respect to the level the lake would have been in the absence of the cause?

A. Yes.

Q. Now, directing your attention again to the outflow in the St. Clair River, what is the effect of this diversion, the proposed diversion at Chicago, upon the quantity of water which would flow out through the St. Clair River?

A. It will diminish the flow ultimately in the St. Clair River an equal amount.

Q. If I may put the question in this leading way: by that you mean that ultimately there will be, if there are 4,000 cubic feet per second diverted at Chicago, that number of cubic feet per second less flowing through the St. Clair River than there would have been if the diversion had not taken place at Chicago—am I correct in that?

A. That is correct.

Q. Do you use the term "net supply" in connection with the quantity of water in the lakes?

A. Yes.

Q. What do you mean by that?

A. I am almost afraid to say, because I shall differ with Mr. Noble, and the man who differs with him is usually wrong. I have said here, net supply is all the water that flows into the lake from streams, springs, seepage, et cetera, plus all rain and snow which falls on the surface of the lake, and

minus evaporation from the lake surface and it is a concrete quantity.

Q. You say it is a concrete quantity?

A. It is a concrete quantity.

Q. Will you explain a little more fully what you mean by that?

A. Why, I don't hardly know; the lexicon would do it a great deal better.

Q. I mean by way of illustration or example.

A. Well, it is a quantity that can be measured, it is a real, an actual quantity, with suitable observation we could measure all these effects and get the net supply, and then we would know that that supply had actually been received by the lakes.

Q. What do you mean by suitable observations?

A. It would be necessary to measure the rain fall, all kinds of precipitation and evaporation, measure all of these quantities which I have mentioned here, accurately, and we would eventually get the net supply, if our observations were correct, if they were properly made.

Q. Do you happen to have any knowledge on the subject of the observations which may have been made along those lines?

A. Why, concerning precipitation continuous observations have been made by the weather bureau for about, less than thirty years. They have measured also various other quantities such as the wind, temperature, humidity and rain fall. From these observations the total amount of precipitation has been determined approximately, of course, the determination is no better than the observation, and the amount of discharge from the lake has been measured at the same time, and the difference between these two has been assumed to be the evaporation. It has been determined in that way and to that extent. That would be the total evaporation for a basin.

Q. Now, referring to items of rain fall, evaporation, absorption, the run-off in the drainage basin of the lakes, and the inflow from the St. Marys River, would the diversion of this quantity of water at Chicago have any effect upon any one of those items?

A. None at all.

Q. In other words, if I gather the result of what you have said, this diversion of water at Chicago is a fixed factor, which will tend, to the extent to which it is operated, to modify whatever condition with reference to elevation that the lake would be in, if that factor had not been produced?

A. Yes. In my answer to the previous question I said that it had no effect whatever on evaporation, precipitation and run-off. I should qualify that by stating that it has an effect on the run-off, not on its total amount, but on its locality; it changes a portion of the run-off from the St. Mary's River to Chicago. It does not change the amount; simply a change in locality. The other items are not affected at all by it, and the run-off is not affected in amount by it either.

Q. I understood you to say that would be eventually the effect that the amount of run-off through the St. Clair River would be decreased by the amount which was diverted at Chicago?

A. Yes.

Q. When you said "St. Marys River" you meant St. Clair?

A. I meant the St. Clair River; it would be ultimately decreased by that amount.

Q. Now, if the net supply were to remain absolutely the same then what would be the effect with reference to the actual elevation of the lake, as a result of this diversion at Chicago?

A. The actual elevation would begin to diminish the moment the diversion at Chicago began, and the elevation of the lake would slowly be lowered, but on account of the large area it takes some time to accomplish the thing, and it takes an infinite time to completely accomplish it.

Q. Well, how long, to substantially accomplish it?

A. In about four years a little more than 90 per cent., a little more than nine-tenths would occur.

Q. How long before half of the effect?

A. A year and a half or something like that, less than two years.

Q. How long would it be before you could say there would be an appreciable lowering?

A. Well, I haven't worked that out; I would have to express that approximately.

Q. Well, approximately?

A. If in four years it reduces the elevation four inches, that would be an average rate of an inch per year. For the first year that would be considerably more than the average rate, so I should expect there would be an inch and a half the first year—something like that—so in the first six months there would probably be three-quarters of an inch.

Q. That is, expressed by one of these formulas of a curve always approaching its limit, and never quite gets there, is that it?

A. Yes, the curve would be an asymptote to it.

Q. I am showing you, Mr. Wheeler, a chart or plat in which certain observations have been platted, of lake heights, platted as ordinates and the discharge as abscissa—that is to say, the lake heights have been so platted that they are represented by vertical lines, and the volume of discharge so they are represented by the horizontal lines, and that chart has been marked Complainant's Exhibit 1, under date, February 15, 1909. On that plat there has been a certain line drawn, expressive of the relation between the lake height and the volume of discharge, the result of which has been the determination of the loss of outflow in the St. Clair River, by reason of the diversion of water at some other point along the lakes. Have you had a copy of that plat presented to you for your consideration? (Handing plat to witness.)

A. Yes, I have had a blue print of this drawing.

Q. Now, Mr. Wheeler, this is a law suit, and one of the questions that is here for determination is, what will be the effect upon the lake elevations of Lakes Huron and Michigan as a result of this diversion of water and the corresponding loss of outflow in the St. Clair River, to which you have testified. Here are the observations and here is a line which has been drawn so as to present a basis for that computation. I wish you would take that up and, as an expert, explain first what you have to say with reference to the drawing of that line and next, what that line shows on the plat with reference to the lowering of the lake level, why you show that, take it up and explain it in your own way.

A. Well, I have examined the data and I find it to correspond with the published data from the Lake Survey Office. I have made a special study of the position of this line which is really the mean line.

Q. If I may interrupt you there just a moment, so that we may get it in the record here, are you able now to give us the references to these reports to which you have just referred, which show that those observations, as platted, are correct?

A. I think I can, I think they are before you on that paper, which you have.

Q. The one that I have?

A. Yes, the first pages.

Q. Now, let me hand this to you, and in your testimony, Mr. Wheeler, where you refer to reports, official records of any kind, it will be helpful if you will indicate so we will have

them here in the record, just to what books you have made reference, so we may be able to find the references easily.

A. I will, wherever I recollect it, and can make the reference.

Q. Yes. We will be obliged to you if you will.

A. I don't remember—shall I read this to you, or just submit—

Q. No, just read them so the Commissioner will get them in the record.

A. Well, concerning the water level tables I find those in the full reports of the Chief of Engineers for 1900, on page 5362, and for 1902, on page 2819, for 1903, page 2837. 1903 again, page 2855—1904, page 4069.

Q. You have given all the references that relate to the data on the plat which you have before you?

A. Yes.

Q. Now, go ahead with your answer with reference to that plat.

A. I have made special computation of this mean line, and I find the position of it practically the same as given here, in some of the sheets almost exactly the same. Let's see, this is the St. Clair River.

Q. Well, referring to your own computation and refreshing your recollection with reference to the plat, what have you to say as to the substantial accuracy of the line that is there drawn?

A. It is almost exactly as I find it, the differences on the plat are hardly perceptible to the eye. I will submit them here. I have drawn in red on this blue print the position of the mean line as I determined it.

Q. Did you make any attempt to determine the degree of precision of the computation?

A. Why, yes, I determined the probable error, I think I have it in my notes, that is one of the things that one don't remember. The diagonal lines on these plates show the exact mean of the observations. This is exact, it is not an estimate, it is susceptible of computation. The agreement of the observations among themselves show the probable error of the increment which really means the position of the line, as determined for the several rivers, as follows: For this one, the St. Clair, it is 227 seconds feet.

Mr. Williams: That means cubic feet per second?

A. Yes, cubic feet per second. It is the probable error of this determination of the increment.

Mr. Wilkerson: How nearly accurate would that be when expressed in simpler and easier words, if you can express it, would you call that a very high degree of precision?

A. Yes, I do.

Q. About what percentage would it be?

A. I have said in my answer that the agreement of the observations among themselves show the probable error, and I consider the small size of this probable error in evidence of the high degree of accuracy in the observations.

Q. Have you, in your own mind, figured out just the percentage of error?

A. Yes, sir; it is——

Q. Its relation?

A. The increment as determined is 25,200 s-f., and the probable error is 227, which would be a little less than 1 per cent.

Q. One-tenth of one——

A. One per cent—it is a little less than 1 per cent.

Q. Now, let us come back to this plat, Mr. Wheeler, and having gone over the questions that relate to its accuracy——

A. Well, perhaps I have not stated all that I might say——

Q. Please state what you have to say then.

A. ——on the matter of accuracy. These observations have been made for determining, what in this trial has been called the increment, we commonly use that term, which simply means the discharge due to one foot of elevation. These results show a close agreement among themselves and great care and accuracy in the observations; but the observations were made mostly in the summer season, entirely in the summer season. They may be different in the winter, they may be different on other occasions, so that the absolute value of that increment cannot be as closely known as indicated. Do I make it plain? The probable error which I give is the probable error of these observations. These observations are not sufficiently prolonged to say that the determination which is sought from them is known with entire accuracy the increment yet may be different at different times, but at the times these observations were made I know——

Q. You know that the basis of the observations, as made and platted on the plat——

A. At that time, when they were made, we know the value of the increment within this limit that I have given.

Q. Now, is there anything further that you would add in

connection with the accuracy of the computation, or have you covered that?

A. I think I have covered it. I have had this line determined, and I have checked the computation myself, and I feel perfectly safe in saying that this red line is the mean line of these observations. It is not an estimate, it is the mean line.

Q. Now, having said that with reference to the accuracy of the computation, I wish you would pick up that plat and explain to us just what it shows as the results of the determination of that line, translate it, so to speak, now, from the phraseology of the plat, to language that the layman can understand.

A. In making an observation to determine the "increment" of discharge, two things are observed, first, the elevation of the Lake surface as shown on the gage. Second, the amount in cubic feet per second of the discharge. Suppose at the time of the first observation the elevation of the lake surface to be 580 feet and the discharge to be 174,200 s-f. Suppose that at the time of the second observation the elevation of the water surface is found to be 581 feet and the discharge 199,400 seconds feet. These two observations together show that the elevation of the lake surface increased one foot and that the discharge increased 25,200 seconds feet. This is the "increment" or the change in discharge corresponding to one foot change in elevation. To show this result graphically the observations are plotted on the sheet as follows,—For the first one a circle is made around the point where the horizontal line representing 580 feet of elevation crosses the vertical line representing 174,200 seconds feet of discharge, and similarly for the second observation, a circle is drawn around the point where the horizontal line representing 581 feet of elevation crosses the vertical line representing 199,400 seconds feet of discharge. If now a diagonal line should be drawn through the two points one could tell by inspection what elevation of surface would correspond to any discharge. The diagonal on the plat is such a line, but instead of being made from two observations only, it is the mean of many observations, made in different years at different elevations. Since a change of discharge of 25,200 seconds feet, causes a change in surface elevation of one foot or 12 inches, it follows that a change in discharge of 1 second foot would cause a change in surface elevation of 0.000476 inch. For the purposes of this case this is a more convenient form for expressing the "increment" of discharge, because the change in surface elevation caused by

any change in discharge or "diversion" can be found by simply multiplying the diversion, when expressed in seconds feet by 0.000476, which gives, in inches, the resulting change in elevation.

Q. Well, now, having drawn the line, what is the result of that plat as to determining the effect upon the level of Lake Huron resulting from this loss of outflow through the St. Clair River?

A. We find that the value of the change for one foot is 25,200 seconds feet, that is, we find that if the discharge is diminished 25,200 seconds feet, that the elevation will be diminished one foot.

Q. Now, then, referring to the scale that is at the side of this plat here, at the head "Reduction in outflow, cubic feet seconds" and the other "Loss in stage, inches," what do you get there as to the—well, on the basis of your computation 10,000 cubic feet diversion, with the corresponding loss of outflow in the St. Clair River, would result in how much of a loss in stage of the lake?

A. It would come from there (indicating) down to there (indicating as shown graphically).

Q. That would be five inches?

A. If 14,000 it would come down to here, seven inches.

Q. Seven inches?

A. Yes, sir; on the natural scale.

Q. In your computation in which you went over these figures yourself, I notice there is a slight difference in the figure which you use in the formula that is down here on the original plat as denominator, a slight difference in figures in the computation. Does that make any substantial difference?

A. It does not make any substantial difference.

Q. In the result?

A. None at all, or hardly any. Hardly any appreciable result.

Q. That is, they are so nearly together that when you come to express the result in lake elevation in inches there is no appreciable——

A. No appreciable difference. I of course stand by my own computations.

Q. Yes.

A. I had them made with great care by an assistant, and I checked them myself, and I have great confidence in their correctness.

Q. Now, then, having explained to us the method through

which this result is obtained, and putting to you as an expert the question as to your conclusion, what, Mr. Wheeler, would be the effect upon the level of Lakes Huron and Michigan of the diversion of 10,000 cubic feet with the corresponding loss of outflow through the St. Clair River in inches?

A. I think I have computed that. You ask for that in inches, and I had the result in feet. I will have to figure it in inches.

Q. Give it to us in feet the way you have it. You may give the result in inches if you will—you say you have the computation in feet—our computations are all——

A. I can make it in inches in a moment.

Q. Very well, then, that would probably be more convenient, because we have been using that result.

A. Four inches and seventy-six thousandths for 10,000 seconds feet.

Q. Have you made the result for a diversion of 4,000 cubic feet at Chicago, with the corresponding loss of outflow from the St. Clair River?

A. It would be one and nine-tenths inches.

Q. That would be at the same rate for——

A. This is the same rate, yes.

Q. It would be at the same rate for any different quantity of water diversion?

A. Yes, sir.

Q. That is to say, it would be in the same proportion for one or two or five or eight thousand cubic feet?

A. True, with this limitation: This is true for any range of level that we know anything about, that we have ever had a chance to observe. It would not be true in an infinite range of level; there would come a time when your range would be distributed, but for anything we have, any range of level we have had this is true.

Q. In giving your result for the diversion of 4,000 feet, have you given that in tenths or in inches—will you look at it again?

A. It is 16/100 of a foot; and for 1,000 feet it would be one-fourth that much; I make it 48/100 inch.

Q. What is it for 4,000?

A. Oh, I made an error in this computation.

Q. I think it is a little over two inches when you come to figure it out. It would be one and nine-tenths inches.

Q. A fraction under two inches?

A. Yes.

Q. A small fraction under two inches. Now then the result of that is that speaking with substantial accuracy the effect of the division of each 1,000 cubic feet per second is, within the limits that there have been any opportunity to observe, a reduction of about half an inch in lake elevation.

A. Half an inch.

Q. Half an inch for each 1,000 feet?

A. Half an inch for each 1,000 feet.

Q. What will be the effect of this lowering on the water in the St. Mary's River at the foot of the locks?

A. That requires rather a long answer.

Mr. Williams: What condition do you mean now, a diversion of 4,000 or 10,000 or 5,000?

Mr. Wilkerson: For any diversion.

A. You mean the percentage.

Q. I mean the percentage of diversion.

A. During the 17 years between 1891 and 1907 there were no large changes in the channel of the St. Mary's River, I mean by that there were no dredgings of any considerable extent done there to affect the current. The slope between the locks and Mud Lake remained nearly uniform, the mean being 2.12 of a foot, that is the water at the foot of the locks was 2.12 higher than in Mud Lake. The observations for those 17 years show that any change in the surface elevation of Lake Huron caused a change in the surface elevation at the foot of the Locks amounting to 58 per cent. of the Huron change. In 1907, the West Neebish Channel was opened. This reduced the slope in the river, the amount is not yet very accurately known. The mean slope for 1908 was one foot and twenty-two hundredths. This decrease of slope would tend to increase the percentage of change, probably proportionally. If so, it would now be about 75 per cent of the Huron change. That is the answer that you wanted, I believe.

Q. Now, with reference to the percentage at the critical points of the St. Mary's River, what are those critical points and what would be the effect of the lowering of the level of the lakes at those points?

A. The critical points in the river are Sailors Encampment, Middle and West Neebish and Little Rapids, and the locks. The percentage of change for Mud Lake being 100 and for the locks as just determined, 75 per cent., the intermediate point would be between 100 and 75. I estimate Sailors Encampment at 98 per cent.; Middle and West Neebish, 90 per cent., and Little Rapids, 80 per cent. This is an estimate that

is made from the geographical position of the points. We have no observation at those points, it is only an estimate.

Q. What would be the effect of the diversion of a certain quantity of water from Lake Michigan at Chicago ultimately upon the outflow of the Niagara and St. Lawrence Rivers?

A. I have not made those computations and could not give them with any great accuracy.

Q. Can you give any——

A. As far as amount is concerned it would be the same, as far as the lowering is concerned——

Q. I was speaking—I think perhaps I did not speak distinctly. I was asking simply as to the amount of loss.

A. Oh, it is the same for those, too.

Q. That is to say, if there is a loss of outflow through the St. Clair River there will ultimately be the same loss in outflow through the Niagara and St. Lawrence Rivers?

A. Yes.

Q. Is that correct?

A. That is correct.

Q. I direct your attention, Mr. Wheeler, to two plats or charts which have been marked in this case Complainant's Exhibits Numbers 3 and 4, respectively, under date of February 15, 1909. Those plats or charts purport to show computations with reference to the loss of level in Lake Erie corresponding to the loss of outflow in the Niagara River by reason of the diversion of a certain quantity of water from Lake Michigan at Chicago. Have you seen those charts before?

A. I have.

Q. Well, what did you do in connection with those?

A. I computed the mean line drawn on the plat.

Q. Did you verify the accuracy of the observations by referring to any——

A. I referred to the published reports and verified them in that way.

Q. Can you tell us to what you referred?

A. It is the same references as before.

Q. The same references as before?

A. Yes.

Q. Now, take up those two plats and follow in the same method of explanation which you followed in connection with the plat concerning the loss of outflow through the St. Clair River, and explain to us what the result of those computations is.

A. The observations as platted, were platted in precisely, a

similar manner, to the one for the St. Clair River. Perhaps it would not be necessary to repeat that, would it?

Q. You can condense that—that is to say, if you followed the same general method, you can say it was the same general method you followed in the other computation.

A. The mean line was computed in the same manner as for the St. Clair River. The determinations are almost exactly coincident with those which were given me on the plat.

Q. If you will pardon me, I want to see, I think the record shows it, but I want to be sure—you verified by the published reports the accuracy of the points as platted?

A. Yes.

Q. And those you have recomputed yourself?

A. Yes.

Q. The diagonal lines?

A. Yes, that is the mean line, the mean of those observations.

Q. Now, then, go ahead with your answer.

A. I find that they correspond almost exactly with those which I found on the sheet. The discharge is for two different sections of the Niagara River; one section gives the increment 21,867 seconds feet; the other section gives it 21,744 seconds feet. The probable error of these, of the first of these, is 157 seconds feet, and of the other it is 143 seconds feet, and as before, the very small probable error is to me an indication of the excellence of the observations and the agreement of the two sections of the river is a still further indication of the excellence and accuracy of the observations.

Q. Now what is the result of that computation in the showing of the relation between the reduction in the outflow, and the loss in the stage of the Lake in inches, as shown by the scale that appears on the plat, have you that computed in feet as you had in the case of——

A. No, I haven't.

Q. ——of Huron. I mean of the——

A. Of the St. Clair discharge?

Q. The St. Clair discharge, yes.

A. I can give that in inches in a short time. For the Niagara River the diversion of 1,000 seconds feet would lower the lake 55/100 of an inch and any other amount in proportion.

Q. Ten thousand would be about 5½ inches, and 4,000 would be about two and two-tenths of an inch?

A. Four thousand would be four times as much as that—well, 2.2 of an inch 4,000 would be.

Recess to April 20, 1909, at 10:30 a. m.

April 20, 1909, 10:30 o'clock, a. m.

Parties met pursuant to adjournment.

EBEN S. WHEELER resumed the stand for further examination by Mr. Wilkerson, on behalf of the Government, and testified as follows:

Q. Directing your attention again, Mr. Wheeler, to the lowering of Lake Huron and Michigan, if they be lowered a certain known amount, and Lake Erie a certain known amount, what would be the lowering in the Detroit River and Lake St. Clair and the St. Clair River, speaking particularly with reference to the critical places in that chain?

A. Well, reading from my notes, observations from 1884 to 1909, of the U. S. Lake Survey—do you wish a reference to that?

Q. Yes, if you can give it to us.

A. They will be found in the reports of the Chief of Engineers from 1900 to 1904. These observations show that a lowering of Lake Huron lowers St. Clair 22 per cent. of the Huron change; a lowering of Lake Erie lowers Lake St. Clair 63 per cent. of the Erie change. If Erie and Huron are lowered an equal amount simultaneously, St. Clair will be lowered 85 per cent.

Q. How did you get that result?

A. That comes from direct observations. The Deep Water Commission—I have forgotten what date—placed observers all along the river from Port Huron to Gibraltar, reading the elevations of many places. They waited until there was a change of about seven-tenths of a foot in both lakes, and read it again. These curves show that while there was a change of seven-tenths at the extremities, there was only about eighty-five one-hundredths in Lake St. Clair, and perhaps fifty-three one-hundredths in the narrowest and rapidest place, which was opposite Algonac. This result is derived from a range of four and a half feet in Huron and three and a half feet in Erie. A similar result is shown by the observations made by the Board of Engineers on Deep Waterways in 1898 and 1899. That is what I have just alluded to.

Q. What have you to say about the probable error in those results, based upon the observations?

A. The agreement of the observations among themselves indicates that the probable error of these results is 8 per cent.; that is, if the lowering of Huron and Erie be given, the lowering of the St. Clair can be found by means of these percentages within 8 per cent.

Q. What do you say about the observations given by the Board on Deep Waterways, as the result of their observations?

A. The observations made by the Board on Deep Waterways in 1898 and 1899 show that if Huron and Erie are lowered an equal amount, St. Clair and Detroit Rivers will be lowered respectively 75 and 91 per cent. of this amount.

Q. What are the critical places between Erie and Huron?

A. The critical places, beginning at the lower end, is first Amherstberg.

Q. What about the percentage there?

A. About 95 per cent.

Q. Of what?

A. Of the lowering in Lake Erie.

Q. What is the next one?

A. Lake St. Clair.

Q. And the per cent. there?

A. That would be about 85 per cent.

Q. The next one?

A. Squirrel Island.

Q. And the per cent. there?

A. About 66 per cent.

Q. And the next?

A. Opposite the village of St. Clair.

Q. And the per cent?

A. 83 per cent.

Q. The next one?

A. Stag Island.

Q. And the per cent.?

A. The same, 83 per cent.

Q. The next one?

A. Opposite Black River, 88 per cent.

Q. The next one?

A. And last in the lower end of Lake Huron, for a distance of four miles, it would be 100 per cent. Now these percentages are determined from the geographical position of these

critical points. We have not observations made at all these points; and they are therefore approximate.

Q. I show you another one of these charts, Mr. Wheeler, that have been marked Complainant's Exhibit No. 2, date February 16, 1909, and ask you to state whether you have seen that before, and what you have done with reference to it?

A. This has been given to me and I have examined the observations, so as to note that they correspond with the published observations of the Lake Survey; and I have computed the diagonal line, or the mean line, recomputed; find it to agree almost exactly with the given one here. On the blue print which I submitted, the line which I computed is shown in red, which corresponds almost exactly with this one. This line shows graphically the discharge which corresponds to a change in stage. It is found that the discharge for one foot of level is equal to 28,870 cubic feet per second. That is the St. Lawrence River.

Q. What would be the lowering effect, therefore, of the diversion at Chicago of 4,000 cubic feet of water per second upon the level of the St. Lawrence River?

A. Since this shows that a diversion of 28,870 cubic feet would lower it one foot, 4,000 feet would be its proportional part. I have not worked that out.

Q. Is the scale that is on the left hand side of the chart substantially correct as expressing the lowering effect of the diversion of this water?

A. Yes, it is correct, and it is marked on the scale here. Ten thousand cubic feet per second would——

Q. A little over four inches?

A. About four and a third inches.

Q. What is the season of navigation in the St. Clair River, Mr. Wheeler?

A. The records of the last six years show that vessels use the Detroit and St. Clair Rivers during every month in the year. The broadest definition of season of navigation would include the entire year.

Q. Taking out now the months where the navigation is comparatively small.

A. During January, February and March the number of vessels is very small, averaging less than 50 per month. In April, the number of vessels is from one to 2,000. In December it varies between 700 and a thousand. I should think a better definition of "season of navigation" would be from April to December, inclusive.

Q. What do you mean by ice effects, as they are used in connection with the St. Clair River?

A. I understand ice effects to be the effects which ice has on the discharge and elevation of the rivers and lakes. Ice, when actually present in St. Clair River, tends to retard the flow, and to raise the level of Huron. These are one kind of ice effects. After the ice disappears, the increased elevation of Huron caused by the ice tends to accelerate the flow in the river, and diminishes the elevation in the lake.

Q. Is there any other kind of ice effects?

A. I think that would include them all. These are also ice effects, but of another kind; one or the other kind is always present. In the aggregate the two kinds are equal to each other. There are times when both are operative, and the final result is the difference between the two. Ice effects are sometimes cumulative; that is, the cold months of winter may raise the level of Huron more than can run down in the warm months of summer. Ice effects are very erratic in their intensity. They may be large for several consecutive years, as they probably were from 1880 to 1886, when the level of Huron was raised one foot. Or they may be small, so as to be almost negligible, as they probably have been in the last few years. The retarding effects of the ice must be small during the season of navigation, generally so small as to be negligible, but this may not always be the case. For example, during the period from 1880 to 1886, it is probable that there were large retarding effects during the months of April, May and December. The retarding effects of ice are present, whenever there is any ice.

There is often ice in the river before the first of December, and therefore the retarding effects generally begin before the first of December. But the December ice is often so thin and broken that its retarding effects may be negligible; and I should say that as a rule it is not large enough to be measurable before the middle of December.

Q. How about the effects in April and May?

A. There is much ice in the river in April; generally broken by passing boats. The retarding effects last as long as there is any ice, but it is usually small by the middle of April. Sometimes ice effects last through May. I should say that the retarding effects of ice would generally be unimportant after the first of May.

Mr. Lindley: What river are you talking about now?

A. St. Clair.

Mr. Wilkerson: How about May?

A. There have been, though rarely, large ice jams in May, and retardation during the whole month. There have also been, though rarely, years when there was no ice in May, and therefore no retardation. I should say that more than half the time the ice effects in May are unimportant.

Q. What information can you give us about ice effects in the St. Mary's River?

A. In St. Mary's River the ice raises the water at the foot of the locks during the winter months, sometimes as much as two feet; an average of 20 years shows about six-tenths of a foot. Above the locks no ice effects are observed.

Q. The observations which appear on the charts which you have examined, and from which has been deduced the lowering effect upon the lake level of the diversion of water at Chicago, the observations, as I understand it, most of them were made out of what you call this ice period, were they, Mr. Wheeler?

A. Made in the summer season.

Q. Made in the summer season. By that you mean the open season?

A. Yes.

Q. What they call the season of real navigation, as distinguished from the season when navigation is practically closed, although during the closed season there are a few boats that pass. Is that right?

A. Yes, that is right.

Q. Now I wish you would take up this subject, Mr. Wheeler, and in your own way give us your conclusions with reference to it. The subject is this: The bearing, if any, which the presence of ice during these winter months has upon this lowering effect of the diversion of water in Chicago; I mean not the actual level of the lake, but upon the lowering effect, the tendency of the diversion, whether it would be to lower the level more than what it otherwise would be?

A. I understand that the ice effects do not in any way increase or diminish or change such quantities as the precipitation, evaporation and final outflow, but it has a disturbing effect which might be compared in one sense to storms. It raises the elevation of the lakes at times. It diminishes the outflow of the river at times. It increases the outflow of the river at times, but as it makes no change in the outflow, it makes no change in the effect of a diversion.

Q. That is to say, if I may interrupt you, in order to get

your idea clearly before us, the presence of more ice for instance in the St. Clair in a given winter is a circumstance that is analagous to more rain, for example, is that right?

A. Would you repeat that question.

Q. I say the presence of more ice in the river in a given winter is a circumstance which would be analagous to there being more rain at a given time.

A. Well, in a limited sense that would be true.

Q. I am speaking now in its relation to the lowering effect, so far as it would modify the lowering effect.

A. Well, I should say that it would change the rate of the lowering, but not its final amount.

Q. Well, suppose you compared it with the wind blowing up stream, on the St. Clair river?

A. That would be analagous in a certain respect. It would diminish the current in the river for a time and later the current would be accelerated because of the water that was held up. But the final result would be that just as much water ran down with the wind as would have done without it, and that is true of the ice effects. The total discharge is not affected by it, although the rate at different times is made variable.

Q. What can you say, Mr. Wheeler, with reference to the relation of this ice retardation to the increment of the outflow in the river?

A. I should say that I know of no reason why it should change it. It is a physical possibility that it might so alter the form of the outlet that it would change the value of the increment, but I can see no reason why it should do so.

Q. Now take these two things: The diversion of the quantity of water from Lake Michigan at Chicago, and the fact that some time in the year there is ice in the St. Clair river. What is the relation of the presence of this ice to the ultimate lowering tendency, if any, of the diversion of the water at Chicago?

A. I think it does not change it in any respect.

Q. That is to say, if a diversion of 4,000 cubic feet of water per second at Chicago had certain definite lowering tendency upon the water in Lake Michigan, upon the level of the water in Michigan and Huron that ultimate lowering effect would remain, even though there were ice in the St. Clair river. Is that the result of your answer?

A. It would, I think. The rate at which that lowering would proceed would, I think, vary somewhat on account of

ice. It would be increased in the winter season and diminished in the summer season, but the ultimate effect, which I believe was your question—

Q. I am speaking about the ultimate result about which you testified yesterday. You said, as I understood you, that the diversion of this water at Chicago had a lowering tendency that while the lowering tendency was never absolutely realized because of the law which you expressed yesterday, yet within a few years substantially all of it would be accomplished?

A. Yes.

Q. Now I am asking whether the presence of this ice in the St. Clair River in any way modifies or affects what you have already stated as to the lowering tendency of the diversion of this water?

A. I don't think that it does. The ultimate effect would be just the same. It is similar to that of a great storm on the lake which might change the rate of the discharge temporarily, but it would not change the ultimate lowering effect of the diversion.

Q. And in your judgment would it have any appreciable effect upon the time which would elapse before this lowering effect would be substantially accomplished?

A. I don't think that the effect would be appreciable. I can conceive that there might be some possible slight effect.

Q. Would it substantially modify the time?

A. It would not.

Q. Have you any information Mr. Wheeler, as to whether the St. Clair river is changing its regimen by scouring out its bottom or banks, so as to make a greater outflow from Lake Huron. If so, to what extent is the scouring taking place, and what is its effect on the level of lakes Huron and Michigan?

A. The Board of Engineers on Deep Waterways in 1900 say: "The mean level of Lake Huron is apparently one foot lower than it was fifteen years ago, which change has resulted from enlargement and deepening of the channels for waterway improvement and from the natural erosion of the bed of the river at the outlet of the lake."

This opinion of the Board caused some alarm. The United States lake survey directed a new survey and an examination of all old ones. Assistant Engineer Haskell reported that: "Surveys of the outlet made between 1867 and 1900 do not indicate any enlargement or lowering of the outlet." It

was further pointed out that while an enlargement of the outlet might explain the fall in Huron from 1886 to 1892, it would not explain the rise from 1880 to 1886. The most convincing proof that there has been no enlargement of the outlet comes from the relations between the levels of Lake Huron and Erie since 1886. Thus if Lake Huron had been permanently lowered one foot about the year 1886, the slope between Lake Huron and Erie would be one foot less after 1886. An examination of the records shows that during the twenty years between 1860 and 1880 (before the supposed subsidence of Lake Huron) the mean difference in level between the two lakes was 8.52 feet. For the twenty years between 1887 and 1897 (after the supposed subsidence) the mean difference was 8.47 feet. This close agreement shows that there has been no measurable subsidence of Lake Huron. The continual degradation of all stream beds is recognized, and it is probable that there is some small wearing in the outlet of Lake Huron, but not enough in the last fifty years to be measurable.

Q. What is the diversion from Lake Erie into the Welland Canal and the Erie Canal?

A. Through the Welland Canal, it is given as eleven hundred seconds feet.

Q. You say it is given as that. Where is it given?

A. This is given by the officer in charge of the canal, and I think that his title is Custodian of the Canal. It was obtained from him by correspondence. I gave it in my report in 1903. That can be found in the Chief of Engineers' report for 1903.

Q. Now about the Erie canal?

A. That is 1200 feet per second.

Q. Any changes since then?

A. I know of no changes since then. Both of these quantities were given in that report of mine, 1903.

Q. Is there any other outflow from Lakes Michigan and Huron, except through the St. Clair River and the Drainage Canal?

A. I don't know of any and I don't think that there is any. I don't think that it is possible that there is any.

Q. Suppose there was such an outlet, and it had a discharge, what bearing would that have upon the conclusions you have stated as to the lowering effect of the diversion of the water at Chicago?

A. It would make no change whatever, for our conclusions

and determinations are made from what is actually flowing above ground and in sight; and it would be of no importance if there was a subterraneau outlet, it would make no change in our results.

Q. Do you know of any inconsistencies in the outflow volumes of the St. Clair, Niagara and St. Lawrence Rivers, which are not accounted for by the ice retardations about which you have testified?

A. In a report dated 1893 I say: Formerly there was an inconsistency between the derived discharges of St. Clair, Niagara and St. Lawrence Rivers; but the investigations of ice effects have corrected the derived discharges, so that their relations are entirely reasonable, and there is no longer cause for the theory that a part of the discharge from Lake Erie passed by underground percolation into Lake Ontario.

I have the same opinion now. It is easy to see how these discrepancies, supposed discrepancies, occurred. The discharge through the St. Clair River is always measured in the summer time, in the open season when, as has been before stated, the outflow was accelerated and increased by ice effects. Therefore, the measurd values were always larger than the mean; and when we come to compare it with the Niagara River the two were found to be nearly of the same size. Considering the drainage basin of Erie this was impossible, was absurd, but since the effects of ice on the measurement in the St. Clair River have been recognized, there is no disagreement now in the relative sizes of the two rivers.

Q. Are you familiar with the hydraulic measurements which have been made in the St. Clair River and in the Niagara and St. Lawrence River, and with the management in charge of that work?

A. Mr. L. C. Sabin was in local charge of the St. Clair work, and Mr. E. E. Haskell and F. C. Shenehon in charge of the Niagara and St. Lawrence work.

Q. Having in mind your experience as an engineer, and having in mind the study which you have given to the results of their work, what have you to say as to the degree of accuracy with which it was done?

A. They were all competent engineers, and their work has been reckoned of the highest order, as is indicated by the fact that all are now in positions of responsibility. I consider their work of the highest order.

Q. And what you have said in that answer applies to the

observations which have been platted on the charts which have been exhibited to you here and about which you testified?

A. It does.

Q. When you were on the stand yesterday, we went briefly into the subject of the probable error of the increment of outflow as determined from these observations. You have made, I understand, a careful and particular examination on that subject, and I would like to have you testify now more in detail about it, if you will, Mr. Wheeler.

A. The increment is determined—I determine it by computation. It is given graphically for better illustration on these sheets. The probable error means that quantity which the truth is as likely to exceed as to fall short. It does not mean that the error cannot be greater, but it means that it is as likely to be less as it is to be greater. That applies to the observations that were used. It does not apply to all determinations that might be made. For example if these same quantities were redetermined several years hence, they might differ from the present determinations by quantities greater than the probable error. The several increments with their probable errors are: St. Clair River 25,200 seconds feet± 227 seconds feet. Niagara, first section, 21,867 seconds feet±157 seconds feet. St. Lawrence 28,338 seconds feet±264 ± 143 seconds feet. St. Lawrence 28,338 seconds feet± 264 seconds feet. That is as badly determined as any, but all are believed to be well determined.

Whereupon a recess was taken to two o'clock, p. m.

April 20, 1909, two o'clock, p. m.

Direct Examination of Eben S. Wheeler, resumed.

Mr. Wilkerson: Q. When we adjourned this morning, there had been a question put to you with reference to the meaning of the term "increment" as it has been used in this connection, and its relation to the diversion of a given quantity of water from the lake at Chicago, for instance. I would like to have you go ahead now with that explanation?

A. "Increment" means the number of cubic feet per second that the discharge of a stream is increased by a rise in its surface of one foot. The increment of St. Clair River is 25,200 seconds feet; therefore the fall caused by any diver-

sion has the same ratio. For example a diversion of one-half of 25,200 seconds feet would cause a fall of a half a foot and proportionately for any other amount of diversion.

Q. The fall of Niagara River I think is 308 feet approximately, isn't it?

A. It is, the total fall.

Q. The total fall of Niagara River?

A. Yes, sir.

Q. What then would be the loss in power to that river of the diversion of 14,000 cubic feet per second at Chicago?

A. 14,000 seconds feet of water falling 308 feet has a theoretical potential of 490,000 horse power. If 14,000 seconds feet are diverted at Chicago, it will diminish the theoretical potential at Niagara 490,000 horse power.

Q. That would be true proportionately would it for the diversion of a smaller quantity of water?

A. It would.

Q. What knowledge have you, Mr. Wheeler, on the subject of data regarding evaporation from the basin of Lakes Michigan and Huron?

A. In a report dated 1902, I found the evaporation from the Michigan and Huron basin to be 208,000 seconds feet. This is from a mean of sixteen years. Evaporation is largely controlled by temperature, the wind, humidity, rainfall, etc. These elements are variable and erratic, making the determination of evaporation difficult and uncertain. I do not think that the evaporation in the basin of Michigan and Huron could be determined for one year with a probable error less than 20,000 seconds feet.

Q. Well, in view of the consideration which you have given to data relating to evaporation, precipitation and so on, what have you to say with reference to any attempted deduction which was based upon these alleged data as to evaporation, precipitation?

A. Well, as I think my own determinations had a probable error of ten per cent., I should not expect any results derived from that determination to have any less error than that.

Q. Is there anything else that you can say with reference to the source of those data, that would be further explanatory of your statement that there is a large probable error?

A. Well, the data concerning all of these elements—

Q. I will refer for instance to the extent of territory

covered and the distance apart of the stations where observations were made, things of that kind?

A. I was going to say that it was taken from the Weather Bureau's records, and their records are made at a large number of stations, but with the area so large, the distance between stations is great, and the determination at a single point only gives the correct result for that point, and the mean result of a large area cannot, necessarily, be as close to the truth. The elements, wind for example, is measured at their stations, and very varying results are obtained. I remember that one year at Chicago, the wind records, or the anemometer was changed from a building here in the city out to the crib, with the result that the wind velocity at Chicago was reported after that about twice as much as before. This illustrates the uncertainty of that kind of observations.

Q. In the very nature of things is it possible that with reference to observations concerning evaporation, precipitation, and matters of that kind, there should be anything like that accuracy of observation which is possible in measuring the outflow through the St. Clair River, for instance?

A. No, the outflow through the St. Clair River is measured with much greater accuracy than the rainfall and evaporation can be measured.

Q. Is the difference so great that it can be said that the only class of data, those relating to the outflow through the St. Clair River, can be used as a basis for obtaining accurate results, while the other class of data cannot be used as the basis for determining anything like accurate results?

A. Why I should say for example that the discharge of the St. Clair River has been determined and can be determined with ten times the accuracy of the evaporation of the Huron and Michigan basin and lakes; I should say that there was at least that ratio between them.

Q. In the course of your examination on yesterday, I think in a general way you went over the subject of the length of time which it would take for the ultimate effect of the diversion of the water at Chicago to be accomplished. I direct your attention to that subject again, and ask you if you are prepared to make a more definite statement with reference to it?

A. It will take about four years for a diversion of 10,000 seconds feet to produce nine-tenths of its ultimate effect on Huron and Michigan. A discharge of 25,200 seconds feet from Huron is equal to one foot of elevation. 10,000 seconds

feet will equal 10,000 divided by 25,200, which is .397 feet. Therefore the lake surface will eventually fall .397 feet. The areas of Lake Huron and Michigan is 45,500 square miles. 10,000 seconds feet would cause a fall in one month of .02 feet. This rate will diminish as the lake runs down. At the end of the first year, the lake will be lowered .184 feet. At the end of the fourth year, it will be lowered .360 feet, which is a little more than nine-tenths of the total lowering. But, as stated yesterday, it will take an infinite time to complete the remainder, that is theoretically.

Q. Having in mind, Mr. Wheeler, that the lakes vary in stage from year to year, and that the surface is affected by the influence of wind; it grows rough in storms, and having in mind the other forces which determine the condition of the surface of the lake, what have you to say as to the effect, injurious or otherwise, upon navigation, of the lowering of the level of the lake by say two or three or four inches?

A. I should say that a loss of draft in a fluctuating and disturbed channel is as injurious to navigation as a similar loss would be in a perfectly calm channel.

Q. Why do you say that; that is to say if there is any reason in your mind other than it seems to be perfectly obvious?

A. Why, a loss of draft in a disturbed or fluctuating channel, for example, would tend to cause the boat to strike the bottom. A loss of draft in a perfectly calm channel would also tend to cause the boat to strike the bottom; and the effect in the two cases appears to me to be entirely similar.

Q. How many boats are there on the great lakes that ply between Lake Superior and the lower lakes, or on the lakes below Superior, that are capable of loading to 19 feet?

A. There are three hundred and twenty-three boats that can load to nineteen feet, and of these there are forty-eight that could not safely load deeper.

Q. How many are there to load twenty feet?

A. There are 275 that could load to 20 feet, and of these 87 could not load deeper.

Q. How many could load to 21 feet draft?

A. There are 188 boats that could load to 21 feet draft, or perhaps deeper; some as deep as 26.

Q. Do you know how many tons of freight are carried on all boats capable of loading to 19 feet, traversing the routes which were referred to just a moment ago, during the season of navigation for 1907?

A. Well, in 1907 there were 47 million tons of freight carried through the Sault locks in boats capable of drawing 19 feet of water. Two million tons of this were carried in boats that could not safely load deeper than 19 feet. There were 45 million tons were carried in boats that could have carried more if the channels had been deeper, which is about 85 per cent. of the freight carried on a 19 foot draft.

Q. Now as to boats that could safely load to 20 feet draft, if the chanels had been deep enough, how much was that?

A. Well, 44 millions of tons were carried in boats that could safely load to 20 feet draft, if the channels were deep enough. Of this, 11 million tons were carried in boats that could not safely load deeper than 20 feet.

Q. How much was carried in boats that could safely load to a draft of more than 21 feet, if the channels were deep enough?

A. Thirty-three million tons were carried in boats that could safely load to a draft of more than 21 feet, if the channels were deep enough.

Q. What determines the amount of the load that can be put on these large freighters; that is to say those boats which have a possible draft of more than 19 feet?

A. Well, those points which we have referred to as the critical points, of which the most important is the Sault locks, at the present time. Boats in the Lake Superior trade that can pass the Sault locks can generally pass all other points en route to Buffalo. The vicinity of Amherstberg is the second critical point in importance; and boats in the Lake Superior trade load with the purpose or the object of going through the Sault locks.

Q. In this connection, we have been speaking here of the depth of the water in this Poe lock; it is probably covered by what I have asked you already, but I will ask you again to explain to us just what relation the elevation of Lake Michigan and Huron has to the depth of that lock, and how the lowering of the level of Lakes Michigan and Huron affects the depth of that lock?

A. The lowering of Lake Huron causes a lowering at the foot of the locks of about 75 per cent. My conclusions were that lowering in Huron caused a lowering of 75 per cent. at the foot of the locks.

Q. In the floor of the lock; also of the Poe lock?

A. That is the Poe lock; yes, it affects all those locks.

Q. Having in mind the number of boats now engaged in

commerce on the lakes, that load to the limit, and have to carry a smaller load if the level of the lake is lowered, and that can carry a larger load if the level of the lake is higher, have you made any computation as to the loss to commerce for each loss of one inch of draft?

A. In 1907 there were 323 boats that were carrying up to the load limit. It is estimated that these boats carried fifteen loads each, making 4,841 loads. It is further estimated that one inch of draft in this class of boats is equal to seventy tons of 2,000 pounds each, which would make a total of 239,150 tons. The cost of transportation of iron ore in 1907 was 67 cents per ton. I mention iron ore; that is the lowest priced freight, lowest priced item that there is. This makes the total cost $227,230 for one inch of draft; or the loss of six inches, a half a foot, in 1907 would have caused a loss to vessel men of $1,336,000.

Mr. Williams: It is understood that the testimony taken before the Commissioner is taken with the same understanding as the testimony taken pursuant to stipulation which is attached to the testimony of witnesses Noble, Haskell, Wilson and Ernst.

Mr. Wilkerson: That stipulation I understand is that all substantial objections to the testimony may be urged when it is offered.

Mr. Williams: That is right.

Mr. Wilkerson: But that any objections to the form of the question should be noted at the hearing.

Mr. Williams: That is right.

Mr. Wilkerson: Q. You have been giving us here some conclusions, Mr. Wheeler, which have been based upon statistics. What had you to do in connection with the Poe lock? When were you familiar with the data upon which these conclusions are based?

A. Why, at the present time I am not in local charge of the Poe lock. For a number of years I was, and I looked after the collecting of the data and also designed and arranged the form of reducing it, and publishing it. I am, and was at that time, very familiar with those details; and at the present time they are conducted in substantially the same way as they were then.

Q. With respect to the size of the vessels which are engaged in commerce on the lakes, are those vessels becoming larger or smaller?

A. They are increasing yearly in size, capacity.

Q. Take the next five years for instance: What do you say about the size and draft of vessels that will be engaged in commerce?

A. I have conferred with some of the vessel men, owners and shippers, and some of the large building firms, and they are expecting an increase in the next five years, a small increase. They expect they will have a length of five to six hundred feet; that is nearly everything that is built. A few now have a length even exceeding six hundred. They expect a draft of 21 to 25 feet.

Q. Do you know anything about the dimensions of the large freight carriers of the lakes, that traverse the waters below Lake Superior?

A. The J. P. Morgan has carried a load of 13,800 tons on a draft of 20.2 feet. Her length over all is a little over 600 feet and her beam is 58 feet. The W. B. Kerr has carried a load of 13,300 tons. Her length is 605 feet; beam 60.2 feet. In these boats one inch of draft is equal to 85 tons of freight. This determination was made by getting the difference between the draft of the boat when she was loaded, and light, the amount that her draft was increased by putting a given load on board her. It was easy to determine how much her draft was increased for a single inch.

Q. Do you know how much water is used in the locks at the Sault Ste Marie?

A. It is roughly estimated that 500 seconds feet are used in all of the locks at Sault Ste. Marie.

Cross-Examination by Mr. Lindley.

Q. I understood you yesterday to say in your direct examination that elevation was or is the resultant of a number of elements or forces. Did you use some such expression as that?

A. Yes, I think I did.

Q. I wish you would now enumerate all of the elements or forces which go to make up that resultant, starting in the order of the most important ones, as you consider them?

A. I could not give you all of them.

Q. Just name them?

A. One of the most important is: (a) precipitation, which includes snow fall and rainfall; (b) evaporation, which tends to diminsh the elevation; (c) outflow. These are the prin-

cipal ones. I think it would be hardly worth while to mention or attempt to mention the infinite variety of other things.

Q. That is exactly what I wanted to get at Mr. Wheeler, was the infinite variety; but of course being infinite you cannot name them all, but name as many as you can.

A. That is rather a hard thing to undertake.

Q. I want to get all we can, that is all. I would be very much obliged if you would enumerate all you can name?

A. I could not undertake anything of that kind. You might ask me to classify all the rain drops I should find. I could not do it.

Q. What I do want you to do Mr. Wheeler if you will, is to name all that you can?

A. Well, I have named all that I can.

Q. That is the three, precipitation, evaporation and outflow?

A. Yes.

Q. Didn't I understand you to say yesterday that it also was affected by humidity?

A. The evaporation is affected by humidity, and indirectly that would affect the supply, I suppose. I said that evaporation was affected by humidity.

Q. And seepage?

A. Well, I don't know that I would classify seepage; that is a part of the inflow. I would not discriminate it from the—

Q. From precipitation generally?

A. Precipitation generally, which would include snow fall and rain fall and hail and everything of that kind that is precipitated into the lake.

Q. Well, then, where will you classify wind? I understood you to give that yesterday?

A. That affects evaporation, and it disturbs the elevation of the lake. I don't know that it makes any permanent effect.

Q. That is exactly what I want to get. You used that expression, it is the resultant of various things. I wanted to get what that resultant was made up of, and if you say there are just the principal ones, precipitation, evaporation and outflow, well and good. Then we will try and see what goes to make up those three things.

A. Well, I said that evaporation was caused largely by four things; rain fall, temperature, wind and humidity.

Q. Yes.

A. And as evaporation affects the elevation of the lake's surface, those four things indirectly do it.

Q. As to precipitation, you include in that simply snow fall and rain fall?

A. Yes.

Q. Nothing else?

A. Nothing else.

Q. And in outflow, you include exactly what?

A. The discharge at the outlet.

Q. The discharge at surface outlets?

A. Yes.

Q. Now are you prepared to say that it has been thoroughly demonstrated that there are no subterranean outlets?

A. I am well convinced that there are none.

Q. Do you think that that is an accepted proposition?

A. I think so. Dr. Gilbert of the Geological Survey in speaking of that said that the land between the lakes was known to hold gas, and he believed that if it would hold gas that it would water, and that there would not be any percolation through it, could not be. But it has not been—you ask if it has been thoroughly demonstrated. I can't say that it has, but I am very well convinced that it is true that there is no percolation of water from one lake to another.

Q. As a subject of investigation, however, it is still an open question, open to investigation?

A. Yes.

Q. Referring to the quotation which you just made a moment ago as to the gas, at what depth generally do we obtain gas?

A. The gas that is being found nearest here, over in Canada, is at the depth of between four and five hundred feet, but in other places it is often more than a thousand feet.

Q. Most generally below the level of the lakes is it not, below the level of the bottom of the lakes?

A. Yes, below the level of Lake Erie; not below the level of Lake Superior, however. Still it is often found in deeper localities than the bottoms of any of the lakes.

Q. While you are speaking of the level of the bottom of these lakes, can you give us the average depth of these lakes?

A. Well, I don't think I can give you the average depth. I can give you the deepest sounding that has ever been made in Lake Superior, very closely; I believe it was 1007 feet, something like that. I happen to remember that because I

assisted in making it. As for the average, I don't remember those things.

Mr. Lindley: I take it some of the exhibits that will be offered will show all the soundings which have been made.

Mr. Wilkerson: We will agree on what that shows.

Mr. Lindley: So I do not care to ask any further questions on that.

Mr. Wilkerson: We will make up a table.

Mr. Lindley: Q. You speak of evaporation. What do you include in the term evaporation?

A. All of the moisture or water that rises in the form of vapor into the atmosphere, after having been on the surface of the earth once; goes back into the atmosphere in the form of vapor, vapor of water.

Q. As you use the term, does it also include what the earth absorbs?

A. No, I don't understand it to include that.

Q. How do you arrive at the amount of evaporation, which you give at something like 208,000 seconds feet?

A. I obtained from the records the precipitation in the basin.

Q. On the surface of the lake, and in the run-off area?

A. In the entire basin, which includes of course the lake. Without saying this for reference, I might say I give an elaborate description of how I did this in a report that will be found in the Report of Chief of Engineers for 1903. It perhaps will be sufficient for your purpose if I say that I sum up the rain fall at all the stations and made such corrections as appeared necessary from their location, and determined the area of the basin carefully and in this way I arrived at the total precipitation into the lake; into the basin and lake together.

Q. Let me ask you right there: You are speaking of the basin of both Huron and Michigan?

A. Yes.

Q. They were considered as one lake?

A. In the discussion we considered that as one lake; that made one quantity. I took from the records the discharge from the outlet, the measured discharge from the outlet at that time, and the remainder I assumed to be evaporation.

Q. Well, then, by that process, is it not true that you considered that which the earth consumed as evaporation, because all that fell upon this basin or upon the run-off area did not reach the surface of the lake, nor was it evaporated

as we use the term, or go off in vapor. Didn't some of it seep into the earth and remain there?

A. No, not as I understand it. The earth is not constantly receiving water and retaining it forever. There is no more goes into it than comes out. And I assume that during the time that I was dealing with it, there was not any more going into the earth than was coming out.

Q. So that in evaporation you accounted for all the rain fall upon the surface of the earth within the basin?

A. Yes.

Q. And considered it as either having run off into the surface of the lake and been evaporated or being evaporated directly from the face of the earth?

A. That is it exactly. I assumed there was only those two ways to account for it. If one has two of those three quantities, he can determine the third one.

Q. Did you determine the evaporation from the basin of any of the other of the great lakes?

A. Yes, from all of them.

Q. From all of them?

A. Yes.

Q. Did your computation cover more than one season?

A. Yes, it was the mean of sixteen years.

Q. The mean of sixteen years?

A. Yes.

Q. Beginning with what year?

A. I don't remember. It must have been about 1884, something like that.

Q. To 1900, sixteen years coming down from 1884?

A. Yes. It might have been a little earlier. The time was governed by the character of the records which the Weather Bureau had. They improved their records very much a certain year, and I went back and included that and didn't go any further back. It made this sixteen years that I say.

Q. Your computation was based upon the weather reports from the various stations?

A. Yes.

Q. And those reports were kept by the government officials in the ordinary course of their official duties, is that right?

A. Yes.

Q. And in your judgment are the most reliable extant?

A. Yes.

Q. And the computation can be made with accuracy from

the data given, but the data is not as full as might be, is that it?

A. That is the point exactly.

Q. In your judgment were the number of stations where records were kept by the government sufficiently great and sufficiently well distributed over the area as to give approximately a correct result of the precipitation?

A. Why I estimated within ten per cent.

Q. Within ten per cent?

A. That is not a very close approximation.

Q. Do you recall what the variation was in the way of precipitation during the sixteen years?

A. That is one year with another?

Q. Yes.

A. I do not, further than it was very great. There were certain dry years and certain wet years, and the range of observation of precipitation was very great.

Q. Speaking of dry seasons and wet seasons, do you mean by that taking a calendar year as a whole, or was it that one calendar year for instance with another would be about the same, but different portions thereof would differ greatly?

A. One calendar year with another would vary very much, vary 50 per cent. perhaps in extreme cases, and portions of years would vary still greater. This is as I remember it. It has been a long time since I have been looking at it, and I am not expected to give very accurate answers to these questions.

Q. No, sir. That will all appear, however, from this report which you have referred us to?

A. Yes, I have given it fully there.

Q. If as a matter of fact there should be found to be subterranean outlets or inflows, would there be any possible way of telling how much if any variation there was in the discharge therefrom or the flow thereto?

A. That is a hypothetical question, I think, where you would have to define what the condition of this subterranean outlet was, whether it was in a measureable condition or not. I don't know of any outlet likely to be found, except the ordinary percolation through strata that permits percolation, and that is very difficult to measure.

Q. There is, is there not, around the whole bank of the great lakes more or less percolation from the soil into the basin of the lake?

A. Yes.

Q. So that whatever you may call it, it is in a manner a subterranean inflow?

A. Yes, it is under the surface.

Q. Now that inflow takes place at all distances below the surface, down as far as the bottom of the lakes?

A. Possibly.

Q. Through different strata?

A. Yes, possibly.

Q. And it is not affected, is it, by the rainfall on the surface of the earth, after you have gone down any distance at all, any substantial distance?

A. Why, it is caused entirely by the rain fall. If there was not any rainfall on the surface of the earth, there would be no percolation through it.

Q. Rainfall in the basin?

A. In the basin, yes.

Q. Might it not be that, say going down a distance of fifty feet, that the percolation below a fifty-foot depth would remain constant, no matter what the rainfall in the basin would be?

A. No, not as I understand it; that would be impossible. Its supply must come from some source, and it would soon exhaust it, if there was no longer any supply.

Q. Isn't it possible when you get down a considerable distance that the supply would come from further away than within the basin?

A. Outside of the basin?

Q. Yes.

A. Yes, it is possible that there might some come into the basin from the outside. It is also probable that an equal amount would go from the basin out.

Q. In other words the percolation there would act just like the inflow into the deep wells, would it not? If you get wells sufficiently deep down into the rock strata and different kinds of strata, slate strata, the inflow into that well is not affected by the lack of rainfall on the surface?

A. I don't understand it that way.

Q. In the immediate vicinity, I mean, of the well?

A. Well, it is not affected instantly by a shower in its neighborhood, but its original source is the rainfall, and if there was no rainfall there would be no percolation.

Q. Exactly, somewhere, but not in the immediate vicinity?

A. It comes from somewhere.

Q. It is true, in what they call the arid region east of

the Rocky Mountains, that they are now getting wells at a sufficient depth that have water in abundance, where they never have any water scarcely upon the immediate surface, or for some hundred miles around there?

A. Yes, that is possible.

Q. And if the percolation into the great lakes were of the same character, it would act accordingly?

A. Yes.

Q. Is it possible, Mr. Wheeler, assuming that this inflow into the great lakes around its banks, in the form of what we speak of as percolation, if instead of being what we commonly think of as percolation, that it comes in there in heavy veins as we might say, so much so that it would almost be a stream, is that so?

A. I don't know of any such thing as that; I don't think it is so.

Q. You have seen them dig wells into the slate, and all at once they strike almost a river of water; at least the water comes up in the wells so abundantly so that they do not even have an opportunity to wall the well?

A. Yes.

Q. Is it not probable, not only probable but likely that there are such subterranean streams or veins of water flowing into the basins around the great lakes?

A. I think it is not probable at all; I think it is very unlikely that there is anything of that kind. I am not prepared to say that there is not.

Q. Where you get this water by the boring of wells and the digging of wells, where does the water come from and where does it go to?

A. Why it comes from the surface of the earth in that vicinity somewhere, more or less remote from the well, and where it goes to is usually—it is taken out of the well; there is no stream there, no flowing stream. The well can easily be exhausted; it don't usually amount to much. You cannot pump much water from the well.

Q. You have seen them where they afford considerable water though?

A. Some wells furnish a good deal of water, but nothing like a stream. You can't get enough for a water power out of it.

Q. Have you ever been through the copper mines of northern Michigan, Mr. Wheeler?

A. I have been in some of them, not very thoroughly though.

Q. Are you aware of the depth of those mines?

A. I know the depth of some of them; some are deeper than others.

Q. Some are 2,000 feet, are they not?

A. There are some 5,000 feet; some more than a mile deep.

Q. Are you cognizant of the inflow of water into those mines, at depths far below the level of these lakes?

A. Why, the wet area, the wet depth is less than 400 feet. Usually the miner will say they don't get any water below that. If they get below that they get into the dry dock, I have understood.

Q. Are you personally cognizant of the inflow—

A. No, I never—

Q —into those mines, of water?

A. I never had charge of the sinking of any pits as deep as that. But I know that the first 400 feet is what they call the water bearing depth, and if they get below that they do not expect to have any more trouble with water.

Q. Assuming that there was a stream, subterranean stream flowing into the basin of the lakes, at a considerable distance below the surface, or near the bottom, and that it was a stream of considerable size, would the depth of water above it have any effect upon its flow into the basin?

A. Yes.

Q. What would be that effect?

A. Why, its source would be somewhere higher than the surface of the lake, and if the surface of the lake was increased, then the slope of this stream, this imaginary stream, this supposed stream would be less. If the surface of the lake was lowered, the slope of the stream would be greater and probably its flow would be greater, if its supply remained undiminished.

Q. That is the flow into the basin would be in the reverse proportion to the depth of the water above it?

A. In case the supply remained constant.

Q. That is the pressure of that water above would have an effect on that flow in, would it not?

A. Yes.

Q. And the greater the pressure the less the flow?

A. Yes.

Q. And that would be the effect on any number of these streams of water flowing into the basin of the lake?

A. Yes. It is equally true with a stream flowing on the surface.

Q. Yes, sir.

A. The surface streams just the same.

Q. Exactly; the higher you raise the water in the main body, into which the smaller stream discharges, it has a tendency to block the water in the smaller stream, doesn't it?

A. Yes. It all goes into the lake, just the same.

Q. Eventually?

A. It gets in just the same. That is another question though.

Q. From the surface.

A. Yes, from the surface.

Q. Because there is only so much of it on the surface, and eventually it all gets in?

A. Yes, sir.

Q. Coming back to the question of evaporation just a moment, Mr. Wheeler: The impression which I get from your answer would be that all the water which falls upon the run-off area gets into the lakes, except that which is simply evaporated from the surface?

A. Yes.

Q. Now, as a matter of fact, the relative proportion of the amount of the precipitation upon the run-off area, which actually does get into the lake itself varies greatly, does it not, from season to season?

A. The proportion of the—

Q. Of the precipitation upon the land area in the basin?

A. Do you mean that the evaporation varies, so that the part that gets into the lake varies?

Q. In proportion to the total amount that falls?

A. Why, yes—

Q. Did you use the term, the run-off varies?

A. The run-off, that is a suitable term; why, yes, the evaporation varies from year to year, and if there is a year when there is great evaporation, then there is a smaller proportion of precipitation that gets into the lake, for that year.

Q. Now in other words the proportion in the run-off varies greatly from season to season?

A. Yes.

Q. Well, the level of the lake would be greatly affected would it not, by the proportion of the run-off to the whole precipitation?

A. Yes, sir.

Q. So that as a matter of fact, the same amount of precipitation in one year might affect the level of the lakes a great deal more than the same amount of precipitation in another year, because of the condition of the earth's surface upon which it fell?

A. Yes, on account of evaporation; more evaporation one year than another.

Q. Now the evaporation from the surface of the lake itself depends largely upon what one thing?

A. Why, it depends upon those four elements that I spoke of, but the most important one is the temperature and the second in importance is the rainfall; the third is the wind and the fourth is humidity; and the other elements that affect evaporation are numberless. But the Weather Bureau say that these four make at least nine-tenths of the changes; are caused by these four elements.

Q. What the layman usually speaks of as evaporation, he thinks of that which goes away in the form of vapor; that depends largely upon temperature, does it not?

A. Temperature is the largest of these. It depends very largely on rainfall; the evaporation is very much accelerated by the rainfall. That has been explained to me in various ways, why a rainfall should make increased evaportion, but it does increase it very much.

Q. Around this city, Mr. Wheeler, and in cities surrounding the lakes, south of here and elsewhere, there are a number of artesian wells?

A. Yes.

Q. A number of hundred feet deep. I think some of them in Chicago are in the neighborhood of 1700 feet in depth, comparatively with an inexhaustible supply of water?

A. Are they flowing?

Q. Flowing wells. What would you say was the source from which the water came. Let us assume that they only come within 50 or 60 feet of the surface, then what would you say?

A. Your question is, where does the water come from?

Q. Yes.

A. Why, it is some area that is 50 or 60 feet higher than Chicago at least; may be much more than that. I do not understand geology very well, but the geologists say that artesian wells are caused by an inclined permeable strata of rock, one edge of which is exposed on the surface, and it goes down at an angle, so that it gets lower and lower; and water

percolates in and fills up this strata and it remains there, would remain there infinitely, would be as permanent as the rock itself, until from some cause or other—we will say an artesian well—it is tapped at its lower extremity or somewhere near its lower extremity. Now, water will rise in the artesian well to the same height as the source that filled this permeable strata, this inclined permeable strata.

Q. It will rise voluntarialy without pumping?

A. Yes, without pumping. And when the surface of the earth is lower, where the well is bored, than the source of supply is, then it spouts up and rises above the surface of the earth. And these are not streams of any considerable size; they are soon exhausted. The supply in this permeable strata is generally soon exhausted; but in some of them it is carried on so rapidly from its upper source that the artesian well has a continuous flow; always discharging from it. So I should say that for any of these wells there is some such a phenomena as that. There is an inclined permeable strata that carries the water down to the bottom of it, and its source is higher than the surface around Chicago, and they have been tapped or pierced by an auger and the water comes up and will rise to the same height as the source, whatever that may be.

Q. If the strata, the slant at the angle which causes this artesian effect, as you say, ran into the lake, there would be that discharge into the lake, would there not?

A. Yes, it would be there in the nature of a spring, only it would be under water.

Q. And if a strata started from the bank of the lake, so that the waters seeped above it in a slanting direction, it might be the cause of an artesian well hundreds of miles away?

A. Yes. And I think that I see the point you are making, which is correct. I should say that there may be such things as that coming from outside of what we recognize as the drainage basin. Some water might come into the basin from what we call the limits of it; we haven't got the limits quite right.

Q. Yes.

A. There is not likely to be much of it, and there is as much of it would be likely to go out as come in, and no very great error in taking the limits as we have taken them, as they show on the surface.

Q. But it is not only likely, but more than probable that

there is more or less of that going on, both coming into the lake and going out from the lake?

A. Yes, I should say so.

Q. And that it necessarily follows that these things are some of the elements which enter into that resultant, namely, the elevation of the great lakes?

A. That may enter into it. The flow of water through permeable strata is very slow, very insignificant. I obtained from Mr. Davis of the Geological Survey, only a year or so ago, data in regard to that; and a flow of 12 feet a day is a rapid one, and a flow of only about three feet a day is an ordinary flow.

Q. Would you say, Mr. Wheeler, that if there were a series of wells dug or drilled around Lake Michigan, at say a very short distance, a quarter of a mile therefrom; and that all these wells were what we term ordinary strong wells with a good supply of water, would you say that that water came from Lake Michigan, or was on its way into the basin of Lake Michigan?

A. I should have to examine the case. It would be as likely to be one way as the other.

Q. But there is no doubt is there that all around the great lakes, and within the whole basin of the great lakes, there are innumerable wells all of which are supplied by subterranean supplies, either going into or coming from the great lakes?

A. Yes.

Q. So that it follows that there is an outlet or outflow, with an inflow through the entire water shed area of the great lakes, underneath the surface of the earth?

A. Yes.

Q. And the amount of that out-flow—

A. Is insignificant.

Q. —is unmeasured?

A. Oh, excuse me; I thought you were looking for the word.

Q. Is unmeasured, is that right?

A. No, it is insignificant.

Q. No, isn't it unmeasured?

A. Yes, insignificant things can be unmeasured.

Q. And being unmeasured, the amount of it is unknown?

A. Yes.

Q. Your table that you referred to will give the discharge through the St. Mary's River for the sixteen years of which you spoke?

A. Yes, through all the connecting rivers.

Q. Are there available equally reliable statistics showing the discharge through the St. Clair River since 1900?

A. Yes.

Q. Do you know, Mr. Wheeler, whether the discharge through the St. Clair River in, say the last five years, has been greater on an average or less than for five years preceding 1900?

A. I don't know.

Q. Would these tables show?

A. Yes; it is exceedingly easy to determine that.

Q. Assuming that the discharge has been equally as great in the last five years as in the five years preceding the opening of the main channel of the sanitary district, would you say that additional precipitating upon the basin accounted for that fact?

A. I should most likely say that.

Q. If the additional precipitation would not account for it then what would you say?

A. Well, then, I would say that it did not occur.

Q. Well, then, you say that the data are wrong if they gave that result?

A. Something wrong somewhere.

Q. Something wrong somewhere?

A. Yes.

Q. And could not be accounted for, is that it?

A. Yes.

Q. I understood you to say on your direct examination that notwithstanding improvement and enlargements in the Detroit river and the St. Clair river for fifty years, that there had been no appreciable change in the discharge through there, is that right?

A. Yes.

Q. Have you in mind substantially the change which has been effected within that period of time in the cross-section of those streams?

A. No, not completely in mind.

Q. Could you give us your best offhand guess?

A. Well, it is certain that docks, many docks and piers have been built out from the shore, opposite Detroit and Windsor and all the cities along the shore. That has a tendency to contract the width of the stream, at least; and I can't give you any estimate of the amount.

Q. Where is the governing section of the discharge between Lake Huron and Lake Erie?

A. I always want that term "governing section" defined before I begin to talk about it, because I make a good many mistakes when I treat it differently from the way my questioner means. What do you mean by the term "governing section"?

Q. I will be the Yankee and ask, what do you mean by the governing section?

A. I can't tell you very well. I have had a good many long discussions with Mr. Haskell on that very question. I know I did not think as he did, but I will say that there is a section at Port Huron where it has the greatest velocity; that is it is the smallest section in the river and has the greatest velocity.

Q. Well, the layman's idea of the governing section would be the smallest section I would say?

A. I would say then at Port Huron.

Q. A section through the stuff had to go, and for which more room to fill up the rest of the channel—

A. I would say that was at Port Huron.

Q. At Port Huron?

A. Yes, in the rapids at Port Huron.

Q. Have you now in mind, Mr. Wheeler, what change, if any, there has been in the area of the cross-section at that point, since the improvement of the great lakes began, by the federal government?

A. Why, none at all. I think I stated that, that Mr. Haskell looked that up and made a report in—I gave the date of it; I have forgotten it now—on which he testified that there had not been any change in that cross-section; and I have not done the work myself, but I presume that is the case.

Q. I understood you to say, however, that the fall from Lake Huron to Lake Erie had remained substantially the same?

A. Yes, it was substantially the same; it is within a very few hundredths of a foot the same within the last ten years; the difference in the level between the two lakes, the mean difference in the last ten years, is within a very few hundredths of a foot the same as it was before 1880, the ten years before 1880.

Q. I understood you to say a few moments ago, changing

the subject for a minute, that there had been a gradual increase in the capacity of the vessels of the great lakes?

A. Yes, there is quite a uniform increase in them.

Q. In your study of that question, is there any particular period of time in which you would say that there had been a greater increase proportionately than at any other period of time?

A. Why, yes, I should say that the years that followed the opening of the Poe lock, and certain other improvements in the river, gave suddenly an increased draft; a possible draft of three or four feet, three feet about, and the increase in the size of the vessls was very rapid at that time. They built them rapidly, so as to utilize this increased draft. Otherwise I do not know that I could mention any particular era when the increase began.

Q. When was the Poe lock opened?

A. 1896.

Q. So that just at that period there was a spurt in the efficiency of the freight carrying vessels?

A. Yes, if I remember right.

Q. It would be 1896, they say?

A. 1896, I should say.

Q. But aside from that period, accounted for as you say, there has been a gradual development, and increase in the capacity of vessels?

A. That is as I understand it. I am not very conversant with it, but I think that is the case.

Q. What was the capacity of the Poe lock, so far as permitting the passage of vessels, when it was first opened; what draft vessels?

A. Twenty-one feet.

Q. When it was first opened?

A. Yes.

Q. Is it the same now?

A. No, it has diminished; the capacity now is considerably less.

Q. Why is that?

A. The improvements in the St. Mary's River have diminished the slope. The water used to be about two to three feet higher at the foot of the locks than it is now, so the lock has lost that capacity, a couple of feet perhaps.

Q. That was occasioned by a change in the slope in the St. Mary's River?

A. Yes.

Q. By increasing the cross-section of it, is that right?
A. Yes.
Q. What was that done for?
A. For the deepening of the channel, and the improvement of the channel; making the new one at West Neebish.
Mr. Wilkerson: Was that a government improvement?
A. Oh, yes, that was a government improvement.
Mr. Lindley: The improvement was supposed to more than offset the detriment occasioned by the lowering of the water at the miter-sills?
A. Yes.
Q. What was the nature of this improvement?
A. Dredging out channels to a greater depth than they had had before; dredging out channels, the West Neebish is one of the largest ones.
Q. The west what?
A. The West Neebish, we call it; that is the new channel that Mr. Sabin opened two years ago.
Q. Was the capacity of those channels before the improvements made therein less than the capacity over the miter-sill?
A. You mean the draft for boats?
Q. Yes.
A. Oh, it was about the same. The improvements were kept along somewhat together. Sometimes the dredging was not completed, or before it was completed there might be a shallow place in the river which was lower than the miter-sill of the lock; but at the present time there is not any such place; the St. Mary's River itself is everywhere deeper than the lock.
Q. You were stationed at the Sault, you say, for a number of years?
A. Yes.
Q. I wanted to ask you a little more particularly on that, more for my own information than anything else, what you know about the current between Lake Huron and Lake Michigan at Mackinac?
A. Through the river?
Q. Through the Straits of Mackinaw?
A. Oh, through the Straits of Mackinaw?
Q. Yes.
A. Why, I don't know anything from direct observation. I have seen some discussions in regard to it, and I have heard from captains, vessel captains; and have no doubt but that the current is sometimes one way and sometimes another;

but a majority of the time it runs from Lake Michigan into Lake Huron, and it is affected by the wind; certain winds will cause the current to run the other way for a short time, but most of the time it runs from Michigan to Lake Huron; that the drainage basin of Lake Michigan is such that we may compute a considerable discharge through there, and consequently there is—must be some current flowing through, because the waters of Lake Michigan do get into Lake Huron, and they must move through the Straits to get there.

Q. Is there an official record kept by the Federal Government of the movement of the water at that point, showing the current?

A. No, there is not, that I know of.

Q. What is it?

A. There is not. I think some sort of record of that kind was kept by the railroads, when they were establishing ferries a number of years ago, but the government never did that I know of.

Q. Mr. Wheeler, you testified yesterday, if I recollect right, that the computation which you made from the data obtained from the survey of the Great Lakes, something of that kind, from which these tables that have been referred to were produced, was in your judgment within 1 per cent. of accuracy. Is that right?

A. Why, not fully right. I did not say that I thought that the result itself was within 1 per cent.

Q. No, the computation within 1 per cent.?

A. The computation——

Q. That you made?

A. ——that I made, indicated that the result which those observations showed was within 1 per cent. of being right.

Q. Yes, sir.

A. Some of them were that way; some were 20, but there were some that was 1 per cent., I know.

Q. You don't know what degree of accuracy the data themselves represent?

A. In the sense that I made them myself I do not; but in the sense that I know that they were made by competent men, and they have been handled by competent men, I do know that they are trustworthy and reliable.

Mr. Williams: Mr. Wheeler, you just testified a moment ago that the result of the observations made tended to the belief that the waters of Lake Michigan run into Lake Huron?

A. Yes.

Q. And I believe you have testified that generally speaking Lakes Huron and Michigan form one body of water?

A. Yes.

Q. Are you familiar with the fact that in the government reports of elevations of these two lakes, they are given as varying to the extent of five one-hundredths of a foot?

A. No, I am not familiar with that.

Q. Are you familiar with the fact that in the report in Bulletin No. 16 of the Survey of the Northern and Northwestern Lakes, page 97, issued in April, 1906, it appears that the elevation of Lake Michigan is—the mean elevation of Lake Michigan is 581.34 feet, and that the mean elevation of Lake Huron is 581.39 feet, showing the elevation of Lake Huron to be higher than that of Lake Michigan?

A. No, I was not familiar with that.

Q. And you have no explanation to offer?

A. No.

Q. As to why those figures are so given out?

A. No, I didn't make them, and I don't know whether they were so given.

Q. On page 249 of the same document, the discharge through the St. Clair River is given as 206,200 cubic feet per second and the variation or the increase of discharge per foot rise of the lake is given as 19,238 cubic feet per second. Do you know, or have you any information as to the data from which that figure of 19,238 cubic feet per second was obtained?

A. No, I am not familiar with that.

Q. Do you know who made the computations that are contained in this report?

A. No, I do not. May I see what report it is (examining same)? I am not familiar with that at all. That is the Bulletin issued for the benefit of navigators, and I have not had anything to do with it.

Q. What is the relation, if any, between your office and the duties that you perform, and the duties of the Lake Survey?

A. The Lake Survey is engaged in surveying and mapping the harbors and the channels; and the office in which I am employed is engaged in the improvement, the deepening of the channels and dredging them; improvement of harbors.

Q. Are there any surveys made in your office, in your department?

A. Not extensive and general ones. In doing our work it is always necessary to make small surveys in the vicinity

of our work; such as we make for estimates and so on; but none that are incorporated in the published map.

Q. Do you know the method or manner of making the observations of the discharge through the St. Clair River, to form the basis of the plates that have been introduced in evidence?

Q. Yes, I know the general method.

Q, At what point in the St. Clair River was the discharge measured?

A. There have been a number of cross-sections where the discharge has been measured. The principal one is below the rapids and opposite the City of Port Huron, from one to two miles below the rapids.

Q. Now will you state in a general way the method of making these observations. I believe you stated yesterday that first you have a gauge reading indicating the elevation of the lake?

A. Yes.

Q. Now how frequently is that gauge read, or is it read constantly?

A. Why, at Port Huron they have a self-registering gauge, read continuously there, but usually when they are making these observations, it would be read every quarter of an hour. An observer is stationed at a gauge to read it and record it.

Q. What instruments would be used in the measuring of the discharge?

A. The principal instrument is a meter, which determines the velocity. The discharge is obtained by getting the area of the cross-section, and the velocity in that area, and those two factors multiplied together give the amount of the discharge.

Q. Are you familiar with the meters that were in use at the time of the observations that are platted upon these plates?

A. Yes, somewhat familiar with them.

Q. What meters were used there?

A. At that point the Ritchie-Haskell meter, as it is called.

Q. That is the meter invented by Professor Haskell?

A. Yes.

Q. How many of those meters would be used at one point, I mean in the making of one observation there?

A. Twelve or thirteen I think were often used. I don't know how many.

Q. Do you know whether the measurements would be taken of all these meters at the same time?

A. Yes, of a large number of them at least at the same time.

Q. And how far apart would they be located?

A. Well, often they were on one vertical line. Perhaps there would be six on a vertical line, so as to get the velocity simultaneously at six different depths, and the sections in which they were read were 100 feet perhaps, so that transversely across the river they would be perhaps 100 feet apart.

Q. How wide is the river at the point you have mentioned, where most of these observations were probably made?

A. Oh, 1,600 to 2,000 feet, somewhere I should imagine.

Q. And in a vertical line from one shore to the other these meters would be used at varying depths?

A. On each vertical line. When they were observing at a certain point in the cross-section, they did at times have these meters suspended vertically, one of them at the bottom, or as near the bottom as it was safe to use it, and the others at uniform distances perhaps above it, and then in the neighboring section, say, 100 feet further, this operation would be repeated in this place, until the whole section of the river had been so occupied.

Q. What is the greatest depth of the river at that point?

A. I think something like between 40 and 60 feet; I don't know what the depth is.

Q. And that is approximately the center of the stream?

A. Yes.

Q. These observations were taken at stated points, each one at a different distance from the shore, to reach the other shore?

A. Yes.

Q. And how near together, if you know?

A. I don't remember that. I did not take these observations myself. You will have before you a man who knows all about it, who did do it, and whose information would be much more accurate than mine.

Q. Have you an opinion as to the degree of accuracy obtained from the observations made of the discharge, by the use of these meters?

A. Yes.

Q. What degree of accuracy would you say was attained?

A. I should say that they could determine the total discharge at a certain date, a certain time, within 3 per cent. I don't remember what they have assigned—the probable error that is given in their work; that can be easily found.

Q. You have a higher opinion of the Haskell meter than Professor Haskell himself, then?

A. Perhaps I am giving it better than it should be. It is not at all surprising that I do have a higher opinion of Mr. Haskell than he has himself. He is a very modest man.

Q. Have you an opinion as to the degree of accuracy of the discharge measurements in the St. Clair River?

A. Yes, but I would not be able—it would not be at all valuable to give an estimate of the percentage of error, by me, when these matters are accessible and can be known correctly.

Q. Do you think it is possible to know correctly and absolutely the degree of accuracy of this discharge measurement?

A. Well, I will have to explain that to you. I think it is possible to know the probable error; that is, to know a quantity which the truth is as likely to exceed as it is to fall short of; that is all that computers claim for it. An absolute truth is not reached anywhere by any one.

Q. According to your computations, using these plates that are introduced in evidence as a basis, the effect of the diversion of 10,000 cubic feet per second at Chicago upon the level of Lakes Michigan and Huron would be about four and seventy-six one-hundredths of an inch?

A. I think that is what I made it.

Q. At what elevation do you compute that?

A. I think that is true for all the elevations within the range that we have been able to observe it; I do not observe any change.

Q. Is there any difference in the effect of that diversion when the lake is, say, a foot higher than the average elevation?

A. No observable difference.

Q. And the same would be true if it were a foot below the mean elevation?

A. Yes, I think so. These results are only expected to be used within the range in elevation that we have observations. We cannot extrapolate and get it correctly outside of that range.

Q. What is the range of elevation of Lake Michigan, that is within the experience of your office or yourself?

A. I think the records show something like five feet but that should be—the ordinary range is less than three feet.

Q. What would you say as to the natural oscillations in

Lake Michigan and the extent of a change of level, oscillations in the level of Lake Michigan?

A. I don't know that I get the question quite right.

Q. Is it true that the level of the lake frequently changes within a very short time.

A. Oh, yes, there are changes, wind changes, barometric changes; that is in parts of the lake. I do not think that the mean level of the entire lake changes very much in a short time. It takes considerable time for that to be effected; but it is only in parts of the lake.

Q. Do you know the extent of that variation?

A. You mean in parts of the lake?

Q. Yes.

A. Oh, there are known cases of two or three feet.

Q. And continuing for what length of time?

A. Oh, several hours. In Lake Erie, I think wind storms have produced still greater effects than that. They have made one end of the lake five feet lower than the normal and the other end five feet higher, making a slope of 10 feet in the lake.

Q. Are there any causes that occur to you for these oscillations, other than wind?

A. Well, there is the well known seiches.

Q. From the plates that are before you and from which you have testified, is the effect of a diversion at Chicago more or less appreciable in Lake Erie than in Lake Michigan?

A. The difference is so slight that I won't say which is the larger.

Q. I think you testified that the effect of each 1,000 cubic feet diversion would be about five-tenths of an inch in Lake Michigan, and fifty-five one-hundredths in Lake Erie, per each 1,000 cubic feet diversion?

A. There is a slight difference between the two lakes; the effect would be a little greater on Lake Erie.

Q. Taking a diversion of 4,000 cubic feet per second, the effect on Lake Michigan would be approximately two inches, and on Lake Erie two and a half inches?

A. A little more on Lake Erie than Lake Michigan.

Q. Two and two-tenths inches. Now, the lowering of the level of Lake Erie two-tenths of an inch more than the lowering of the level of Lake Michigan would, in itself, have a tendency to lower Lake Michigan further, would it not?

A. Yes, they interact on each other infinitely.

Q. What is the level, or the elevation of Lake Erie as compared with Lake Michigan?

A. Lake Erie is about 8½ feet lower than Lake Michigan.

Q. Have you read the testimony given in this case by Professor Haskell?

A. No, I have not.

Q. Professor Haskell in his testimony states that the effect of a diversion at Chicago would be about 80 per cent. in Lake Erie of what it would be in Lake Michigan. He had before him the same plates that you have. I will ask you whether or not you can account for the difference of opinion that is apparent between your opinion and that of Professor Haskell.

A. No, I have no means of accounting for that.

Q. What would you say as to the accuracy of this general statement, Mr. Wheeler, a statement made by Mr. Wilson, a witness called on behalf of the Government: "In a series of reservoirs such as the Great Lakes are, the effect of diversions generally decrease, as they go down to the source." What would you say as to the accuracy of that statement?

Mr. Wilkerson: Whose statement is that?

Mr. Williams: Mr. Wilson's, Secretary of the International Waterways Commission.

A. If the increment increased as it went towards the outlet, that would be true; but whether it does or not must be determined by the actual conditions as they exist, by measurement. In going from St. Clair to Niagara the increment diminishes; it increases again in the St. Lawrence. Therefore his statement would be incorrect for the Erie section, and true for the St. Lawrence section. But that it is generally true in all systems, I should not agree with that at all. I should want to have it measured, and it might or might not be true.

Q. Would you say that the effect of a diversion at Chicago would be more or less noticeable in the Detroit River than in the St. Clair River?

A. No, I should say that there was no difference.

Q. They would be both the same?

A. They would both probably be the same.

Q. And would it be any more or less noticeable in either the Detroit or St. Clair Rivers than in Lake Michigan itself?

A. Oh, it might or it might not. That is a question that involves the channel conditions to such an infinite extent that no one can give any answer on that at all. If you would

care to look at a curve that was made by the deep waterway people from actual observations, showing the change in level at all points in the St. Clair and the Detroit River for a change in level in Lake Huron and Lake Michigan, you would see that it is different at every point between Port Huron and Gibraltar, and that can only be explained from the character, nature of the channel, its cross-section and the slope and so on.

Q. Would you say then that it was practically impossible to determine the relative effect upon the level of those rivers?

A. Yes. If you like I will get that illustration that I speak of, and I think perhaps you will understand my position better if you will look at it (producing same). It is impossible to determine it accurately, with any very great degree of accuracy, because you can see they do not obey any law between them; that we have discussed and demonstrated to an extent, so that we cannot divide it up into sections and give the functions of each section.

Mr. Wilkerson: You do not mean to say it is impossible to determine whether there is any effect?

A. Let me hear the question once more.

(Question read to the witness as follows: "Would you say then that it was practically impossible to determine the relative effect upon the level of those rivers?")

Mr. Williams: In its relation to the effect upon Lake Michigan; that is what proportion of the effect that is seen in Lake Michigan would be observable on those rivers?

A. On the rivers?

Q. Yes.

A. Well, I would not say it was impossible to determine it approximately.

Q. Accurately.

A. Accurately, it is impossible to determine it accurately; that is for me to do it, because I have not the data.

Q. That is what I mean.

A. I can determine it approximately.

Q. Would it be possible to determine accurately the effect, relative effect upon the level at any one of the critical points mentioned by you?

A. It would be possible, if the proper observations were made at that point.

Q. Do you know whether the proper observations have been made at those points?

A. At many of those points, no observations have been made, and the estimates that I have given, I have given from

the geographical location of the point. They are not expected to have the accuracy that those points which were determined by careful observations have.

Q. What is the low water period in Lakes Michigan and Huron?

A. The recent low water period was in 1895 if that is——

Q. During what seasons of the year would you say that the water is at its lowest stage?

A. I don't remember what month it is; February, I guess.

Q. And generally speaking during the winter months?

A. Yes.

Q. Now have you an opinion, and if so what is it, as to why the water in Lake Huron and Lake Michigan is, generally speaking, at a lower stage during the winter months, when the ice effect would be most noticeable in diminishing the outflow through the St. Clair River?

A. The elevation, as I have had occasion to say, is the algebraic sum of all the causes, and I suppose the reason is the algebraic sum of all the causes producing it.

Q. The tendency of the ice gathering in the St. Clair River is to diminish the outflow through the St. Clair River, isn't it?

A. Yes.

Q. And the diminishing of the outflow would naturally result in raising the level of the lakes, Huron and Michigan?

A. Yes, and then if you ask me the still further question, why don't it make them higher, I say it is because the total height depends on other causes as well, upon the algebraic sum of all of them; that one is not sufficient to do it.

Q. Do you know what the aggregate amount of the storage in Lakes Huron and Michigan was for a period of three years, as shown in the report of the Chief of Engineers for 1903; the storage for the months of December, January, February, March, April and May, caused by the diminished flow, in consequence of the ice in the outlet of Lake Huron?

A. I don't remember what that was.

Q. Suppose that the total stored water for those months aggregated more than the entire year's supply for the Sanitary District's main channel, what would you say as to the effect of that diversion through the main channel upon the level of the entire system of great lakes?

A. How many cubic feet was the diversion that you speak of?

Q. Assume that the diversion was 10,000 cubic feet.

A. I think that I have stated that several times, what it would be. It would be something like five inches.

Q. Would it make any difference that there was more than enough water stored in those lakes during those months——

A. On the effect the diversion had?

Q. Yes.

A. Not a particle. The effect went into the algebraic sum and helped to make it smaller.

Q. What percentage of the effect of the diversion at Chicago of a given amount of water from Lake Michigan would be noticeable in the St. Lawrence River?

A. The amount, do you mean, or the effect on Lake Ontario?

Q. I think you testified with reference to the St. Lawrence River?

A. I don't think I testified anything definite because I have not looked that river up; but the discharge through the St. Lawrence River would be diminished by the same amount as the diversion. Its effect on Lake Ontario would not be as great as it would be on Lake Erie.

Q. You gave the increment of discharge in the St. Lawrence River?

A. Yes.

Q. And how much is that?

A. Twenty-eight thousand and something; I don't remember.

Q. And if you diverted 10,000 cubic feet at Chicago, in your judgment there would be ten twenty-eighths of a foot lowering in Lake Ontario?

A. Yes.

Q. And have you any information from which you can give an opinion as to what the extent of the lowering would be in the St. Lawrence River itself?

A. No, I have not; perhaps such information is available but I don't happen to have it.

Whereupon an adjournment was taken to April 21, 1909, at the hour of 10 o'clock a. m.

April 21, 1909, 10 o'clock a. m.

Parties met pursuant to adjournment.

EBEN S. WHEELER resumed the stand and was further cross-examined by Mr. Williams as follows:

Q. Mr. Wheeler, on your direct examination, I believe that you referred to a report made by you in June, 1903, and shown in Appendix FFF of the report of the Chief of Engineers for that year?

A. Yes, I made such a report.

Q. And that was the report that is contained from pages 2855 to 2862, inclusive, of that volume, which I have indicated?

A. Yes.

Q. What have you to say as to the reliability and accuracy of the computations made and shown and the facts set forth in that report, at this time?

A. The computations were very carefully made and were checked; and contain, so far as I know, no errors.

Q. As to the data contained in the report, what do you say as to the reliability of that data, that is used in the making of the computations?

A. I will say, first, that I believed it to be at that time, and I still believe it to be, the best extant. I will say, second that some of the observations had greater accuracy than other portions; that probably some part of the data, there was an error of 20 per cent.; some part of the data would lead to errors of 3 per cent.

Q. Will you indicate as to the different subject-matters, which data have a probable error of 20 per cent. and which 3 per cent.?

A. I should say that data relating to meteorology.

Q. What percentage of error would you say there was in the data from which you make your computations respecting evaporation?

A. I should not be surprised if there should prove to be 20 per cent. error in that; there may be much less.

Q. And what percentage of error would you say there was in the data respecting rainfall?

A. That is a part of your first question, as I understood it. That includes rainfall.

Q. Evaporation includes rainfall?

A. Yes, it is a function of rainfall. At any rate the answer applies to it.

Q. About 20 per cent.; that is it is possibly 20 per cent. What percentage of error would you say there was in your data from which you made your computations respecting the discharges through the St. Clair, Niagara and the St. Lawrence Rivers?

A. Probably less than 10 per cent.

Q. What percentage of error in your data is there as to the areas of the lakes, Lake Erie?

A. I didn't understand that.

Q. What percentage of error would you say there may be in your data respecting lake areas?

A. That is given in the report. I do not remember it.

Q. I think you gave the areas, but not the probable error?

A. I think I did, page 2856.

Q. You say in order to make an approximate estimate of the error in the determined area of the drainage basin, it may reasonably be assumed that the best located part of the boundary is never more than six miles in error, and this not oftener than once in 100 miles. And you said then that it is probable that the areas are correctly determined within less than 2 per cent.?

A. That is of the drainage basin.

Q. That is the drainage basin. Now as to the surfaces of lake areas, does the surface of the lakes——

A. I think you will find the same thing, the method of determining them is given there. You will find it is stated they were divided into rectangles that were bounded by parallels and meridians.

Q. Can you by referring to your report answer definitely the question as to, in your opinion, a probable percentage of error in the determination of lake areas?

A. Well, I say this much about it at that time, and I could not say any more or better at the present time: "Quadrilaterals, of one degree or less in extent, bounded by meridians and parallels were selected, so as to completely cover the basin. This gave a polygon, the sides of which were meridians and parallels. The total area of this polygon was determined accurately from geodetic tables of areas. Those small parts of the polygon which extended outside of the boundaries of the basin were measured with a plainimeter and subtracted; the remainder being the area of the basin. This work was done with care and checked, and it is believed that the areas of the

lakes and basins as above given on Plate 1 are as accurate as extant maps will permit." I could not say any more than that. A long time has elapsed since doing the work, and I knew better then than now.

Q. You say that the computations made as to lake areas were as accurate as those made relating to the drainage basins?

A. Yes, they are more accurate.

Q. And the determinations would be more accurate?

A. Yes.

Q. What would you say as to the percentage of error in the determinations arrived at with reference to the elevations of the several lakes mentioned in your report?

A. Well, I don't know that I would say anything about it. If one knew what his errors were, he could give an accurate result. It is an unknown quantity.

Q. You have an opinion with reference to it, the same as with reference to the other matters concerning which you have testified, where there was a probable percentage of error?

A. Well, I should say that it was less than 10 per cent.

Q. That is the percentage of error. Does that refer to the computations or to the data from which the computations were made?

A. It refers to the data.

Q. The computations you consider absolutely accurate?

A. So far as I know no errors were left in it.

Q. Is 10 per cent. as near as you would want to testify as to the probable error in the data respecting lake elevations?

A. Yes.

Q. Are we to understand then that these figures shown on page 2867, showing the mean monthly elevation of Lake Superior above the locks at St. Mary's Falls canal, might possibly be an error to the extent of 10 per cent.?

A. You asked what my opinion was, and I said my opinion was it would be less than 10 per cent.; so you are at liberty to understand that.

Q. From the data before you, at the time of making that report, would you now therefore be unwilling to say that, taking, for instance, the elevation of Lake Superior for December that figure, 602.14, might be 662.14 or 552.14?

A. I should be quite willing to say that it would be less than 10 per cent., but I am very unwilling to say what it would be or that it would be more——

Q. I said that it might be either more or less to the extent I mentioned?

A. I am unwilling to testify to that. I think it is less; that is my opinion.

Q. Are you willing to express an opinion that there is a percentage of error in that data of less than 10 per cent.?

A. No.

Q. Do you believe, Mr. Wheeler, that the actual elevation of Lake Superior was either 10 per cent. more or 10 per cent. less than the amount shown by the data to which your attention is called?

A. I haven't any fixed belief on that question.

Q. Are you familiar with the methods by which these elevations were determined?

A. Yes, somewhat familiar with the methods.

Q. Now, taking the Table 4 shown on page 2870 of this report, relating to the mean monthly elevation of Lake Erie at Cleveland, would you answer the questions as to the probable error in the data as to those elevations in the same manner that you did with reference to the data respecting the elevations of Lake Superior?

A. Yes. I have no means of determining it.

Q. And the same would be true as to the elevations in Lake Huron?

A. Yes.

Q. And Lake Ontario?

A. Yes.

Q. Now suppose that as a matter of fact the elevation of Lake Huron was actually 10 per cent. greater, higher than that shown by the data here submitted, and that the elevations of Lake Erie were actually 10 per cent. less than those shown by these tables, would you say then—what would you say then as to the accuracy of the computations, the determinations, made by you on the basis of that data?

A. Why, I should say that the computations were entirely accurate.

Q. As to the results obtained?

A. I should say that the results had had the errors of the observations in them.

Q. Do you think that it would be possible, Mr. Wheeler, that there would be a difference of over 100 feet in the elevations of Lake Huron and Lake Erie?

A. Lake Huron and Lake Erie, a difference in the elevations of over a hundred feet?

Q. Yes.

A. No, I don't think there would likely be any such difference as that.

Q. And yet if there was an error of 10 per cent. in the data respecting the elevation of Lake Huron, and an error in the other direction of 10 per cent. in the elevation of Lake Erie, as shown by this data, it would show a greater difference than 100 feet?

A. I said that I thought it would be less, but I am not inclined to tell you what the error of those observations was, for I know nothing about it; it is an uncertain question.

Q. How much less would you say than 10 per cent.

A. I would not like to say. I can only give you an opinion within limits. This accurate knowledge of the error is impossible.

Q. But 10 per cent. is as near an accurate answer to the question as you would care to go?

A. I don't care to make the limits any nearer.

Re-direct Examination by Mr. Wilkerson.

Q. In your cross-examination yesterday, Mr. Wheeler, you were asked some questions and made some replies with reference to alleged or possible seepage into the lake. What have you to say further on that subject with reference to the effect of that upon the diversion of this water at Chicago?

A. I should say that there is a possible seepage into the lake; that a part of the precipitation may be returned, or get into the lake in that way; that it is entirely immaterial whether it gets in under ground or in surface streams. It has no effect whatever on the Chicago diversion, or in other words the Chicago diversion influences the level of the lake just the same, whether there is much or little seepage.

Q. That is to say if the effect of a diversion of a quantity of water from the lake at Chicago was to lower the elevation of the lake by two inches, that effect would be the same whether all the water came into the lake either by rainfall on the surface, by flowing in on the surface of the land, or whether it seeped in. Is that what you mean?

A. That is what I mean.

Mr. Williams: I object to counsel framing an answer for the witness, and testifying himself. I object to the form of the question.

Mr. Wilkerson: Q. Now, Mr. Wheeler, on yesterday you

were also asked some questions with reference to the elevation of Lakes Huron and Michigan during the ice period, as compared with the elevation during the open period. And you made some explanation of the factors which caused the holding back of the water by the ice during the ice period, not to have the effect of actually raising the elevation of the lake. Now what in your opinion is the cause of that condition?

A. I don't know that I clearly understand the question.

Q. You said that the fact was that during the ice period, the elevation was lower than it was during the other period, as a matter of fact, although the ice did hold the water back?

A. I don't remember that I said that; it may on occasions be that; it is not necessarily that way.

Q. It is that way sometimes?

A. It is that way sometimes.

Q. When that is the case, to what is that due?

A. It is due to the other elements that enter into the elevation of the lake surface; the ice disturbance is only one, and the final effect on the lake surface is the difference between all those that raise it, and all those that lower it.

Q. And the fact that the snow does not melt in the winter would be one of them, I assume?

A. That would be one. That is when it is stored on the shore it permits the lake to run down; when it melts and runs off, it has a tendency to raise the lake.

Q. I would like to ask you a few questions in reference to the elevation, with reference to the probable error in these figures found in this report of 1903, so far as they relate to the elevation of the lakes. Now I understood you to say that you were unwilling to express an opinion that the figures as set down were more nearly accurate than say within ten per cent. of the truth?

A. I don't think I said that. I said I was willing to express an opinion that I expected that they were.

Q. They were within—much below the ten per cent.?

Question objected to by counsel for the defendant.

A. That they were below 10 per cent.

Q. Now the figures that are set down here show the elevation of these lakes in the first place above the sea level, is that right?

A. Yes.

Q. Then there is also a statement of the elevation of the lakes in relation to the locks at St. Mary's Falls, and at Sand

Beach; that is with reference to zero on the gauges at those points?

A. I would have to look at it to see. (Referring to same.)

Q. There is a statement at the head of those columns there, one relating to—

A. These figures have reference to sea level. That means that it is 602.60 of a foot above sea level.

Q. Now, if you take as a standard and assume the accuracy of that figure, the elevation of the locks above the sea level, the wall of the lock above the sea level, then the difference between that figure and the figure which is put down as above the sea level would be the elevation of Lake Superior above that lock wall?

A. Yes.

Q. Did you have charge of these gauge measurements at any time?

A. Yes, for some time.

Q. I wish you would tell us just how those are made, just how you go about determining the elevation of Lake Superior below the lock wall?

Mr. Williams: I object to the question on the ground that it is not re-direct examination.

Q. Answer the question?

A. There is a staff gauge installed at the head of the canal, with a scale with a zero, and the elevation of the zero above the level of the sea has been determined by precise levels. The observer takes a scale resembling a yard stick somewhat, and he measures the distance between the surface of the water and the zero of the gauge which he records in a note book. This he does three times a day. That is one form in which the measurements are made; and that was all the form for many years. But during a part of the time there has been a self registering gauge established which records the elevation in a continuous line, so that the elevation can be found at any instant of time. But the former method enters into these tables much more than the latter one does.

Q. When you have three readings a day, you make a mean of them do you, monthly mean?

A. Yes, that is reduced to a monthly mean and those monthly means appear in those tables.

Q. Now, if we were to assume the accuracy of the figure which is put down as representing the level of the wall of the lock, the elevation of the wall of the lock above sea-level, and the figure which it was desired to obtain was one which ex-

pressed the difference between that and the level, we will say of Lakes Huron and Michigan, and of Lake Superior, what would you say as to the accuracy with which the figure representing that difference could be stated in, we will say, hundredths of a foot?

A. I could say that the work is done by competent observers and the record is accurately made and is properly reduced, and as to what the error which might come in from all other sources in the observations is, I don't know,—I don't like to state. You are asking me something I would like to know about, but I don't.

Q. Do you think that figure has been determined with respect to the elevation of the wall of the lock within one-tenth of a foot?

Mr. Williams: I object; wait a minute.

A. I don't remember—

Mr. Williams: I object to the question as leading, and not proper re-direct examination.

Mr. Wilkerson: Answer the question.

A. I don't remember what the derived probable error is—it has been obtained and can be found in the reports. I should imagine it would be less than a foot, certainly less than two feet. That is an opinion only.

Q. The thing that I want to have clear in the record, Mr. Wheeler, on this question of probable error is to have you explain, if there is any further explanation—if there is anything further that may be added to what you have stated already, the difference between the term "probable error" as you used it in referring to these figures, which represent the elevation of the surface of any one of the lakes above sea level and the term "probable error" as you used it with reference to a figure which will express the difference between the elevations, we will say, of Lakes Michigan and Huron and Lake Superior, or Lakes Huron and Michigan and Lake Erie, without regard to the absolute accuracy of the figure with respect to the sea level.

A. The probable error of the observation is the probable error of that part that was observed. For example, if the difference between the zero of the gauge and the water surface is one foot, and the observer measures one foot and records it, and you ask me the probable error of that observation, and I say that it is less than ten per cent., I mean that I think he has measured it within one-tenth of a foot. It is

measuring the quantity of the thing and observed to which the probable error refers.

Q. And that is what you had in mind when you used the term ten per cent.?

A. Yes.

Q. Now having three observations a day, that would run up to ninety observations in a month, what would you say as to whether or not the probable error in that number of observations would fall much or little within the ten per cent. limit which you named?

A. I should expect, as the observers are competent and careful, that it would be less than ten per cent.

Q. Well, then, when you were speaking with reference to the probable error in these tables, showing the mean elevation of the lake, do I understand that you used the term "probable error" in the sense which you have last defined it, taking its relation to the thing which was observed—

A. Yes, sir.

Q. —and not to a probable error of ten per cent. of 602 feet for instance, when the subject under consideration was the difference in the level between Lake Michigan and Lake Superior—

Mr. Williams: Just a moment; I object to the question as improper in form—

Mr. Wilkerson: I wish you would just explain fully, I want to get here a precise statement of what you mean by that term "probable error."

Mr. Williams: I want the record to show that I protest against counsel putting words in the mouth of the witness and telling him what he wants him to testify to. It has been done repeatedly, and it is becoming worse and worse as we go along.

Mr. Wilkerson: I think counsel, both counsel and the witness, are amply able to take care of themselves, and will be, when the record is submitted to the court. Proceed with your explanation, Mr. Wheeler.

A. Is the question to be answered?

Q. Yes, sir.

A. The probable error of an observation is the probable error of the thing observed. It is not the error of a quantity that may be made up of the observation and many other things added to it; it is the thing observed. That is what I mean by probable error. As I said before, if we measure the distance between the surface of the water and zero, and

that distance is one foot, and the probable error is less than ten per cent., I should say that it was less than one-tenth of a foot. Now it would be easy to determine the distance of the zero of the gauge from the center of the earth, and insert that in the table, and then my statement that it is less than ten per cent. does not mean one-tenth of the distance to the center of the earth.

Q. Certainly; but it means ten per cent. of the thing which has been observed?

A. Ten per cent. of the thing observed. In order to make this clearer, I think I ought to add there is a probable error in the distance above sea level. The quantities in the table there seem to be made up of two things. One is the elevation of the zero of the gauge above the sea level, and another is the elevation of the water surface above the zero of the gauge, or below it as the case may be. Both of those quantities have probable errors and when I am speaking of errors of observation, water level observations, I mean the water level observations. I don't mean the precise level work from there to the sea.

Mr. Wilkerson: That is all.

Mr. Williams: That is all.

Mr. Wilkerson: These pages of the report of 1903 that the witness has referred to in the course of his testimony may be treated as identified by the witness as figures in a report, by you, wasn't it, Mr. Wheeler?

The Witness: By me.

Mr. Wilkerson: Figures in a report prepared by him.

Mr. Williams: Well, the report itself, together with the tables attached thereto, he testified from those observations, showing the elevations.

Mr. Wilkerson: This report may be treated as having been identified by the witness.

Mr. Williams: Yes, sir.

Mr. Wilkerson: Of course, when it comes to offering it on either side the question of the materiality and relevancy may be raised.

Mr. Williams: Of course those are reserved anyway.

Mr. Wilkerson: But the report may be treated as identified by the witness, at the request of counsel for the defense.

LOUIS C. SABIN, a witness called on behalf of the complainant, was first duly cautioned and sworn, and testified as follows:

Direct Examination by Mr. Wilkerson.

Q. What is your full name, please, Mr. Sabin?
A. Louis C. Sabin.
Q. Where do you live?
A. Sault Ste. Marie, Michigan.
Q. What is your occupation?
A. Civil engineer.
Q. In the government service?
A. Yes, sir.
Q. What branch of it?
A. The corps of engineers, under the Corps of Engineers.
Q. Just what is the scope of your duty now?
A. I am in local charge of the improvements being made by the War Department on the St. Mary's River and the general superintendent of St. Mary's Falls Canal.
Q. How long have you held that position?
A. Three years, about.
Q. Are you a graduate of any college?
A. Yes, sir.
Q. What college?
A. The University of Michigan.
Q. What degree?
A. Bachelor of Science and Civil Engineer.
Q. What year?
A. 1890 and 1894.
Q. I wish you would state briefly what experience you have had since you left college?
A. As assistant on the improvements of St. Mary's River from 1890 to 1897, inclusive; precise measurements in Texas, 1898; surveys and discharge observations for the Lake Survey, 1898 to 1903; assistant on the St. Mary's River improvement, 1903 to 1905; secretary of the American Section International Waterways Commission, 1905 and 1906; assistant St. Mary's River improvements, 1906 to date.
Q. Now, just what connection have you had with hydraulic measurements of the Great Lakes, a little more in detail?
A. I was in local charge of the measurements of the discharge of the St. Clair River.
Q. When?

A. From 1898 to 1902.

Q. And prior to that?

A. In 1896 I assisted in measurements of the St. Mary's River, and in some hydraulic studies in connection with those measurements.

Q. And after that time have you given—

A. I think that covers it.

Q. That covers it, your hydraulic work.

A. That is the hydraulic work, yes.

Q. What work did you have to do on the International Waterways Commission?

A. The ordinary executive work of the secretary of the American Section, and such hydraulic studies as were made during the time of my holding that position were under my local supervision. Those studies included the effect of regulation works on Lake Erie. I think that is as far as I need to—

Q. Now, speaking of these hydraulic measurements, particularly those relating to the discharge, the quantity of water that is discharged through the St. Clair River, I think you said you had to do at one time with those measurements?

A. Yes, sir.

Q. I wish you would tell us how those are made.

A. The instruments used to measure the actual velocity of the water passing a given section were current meters of the Haskell type. By measuring the velocity in each of several points in a cross-section, and in multiplying the resultnig velocity by the cross-section of the water in that section, gave the amount of water flowing past that partial section of the river, and the summation of these partial discharges gave the total discharge for the conditions under which the observations were made.

Q. Now, in determining the relation which the elevation of the lake has to the quantity of water which is discharged through the river, is there any set of observations made, any other?

A. Yes, sir.

Q. That you have to make observations—

A. On the St. Clair River?

Q. Yes.

A. Yes, sir; there have been some observations made since those of which I had local charge.

Q. I mean, suppose the thing which we wish to determine is the relation which the quantity of water which is dis-

charged through the river bears to the elevation of Lake Huron—

A. Yes.

Q. —what other observations are made to be used in connection with those observations, so you can—

A. I do not know that I can give the dates correctly; I know the work has been carried on since I left. That is a matter of record.

Q. Well, I mean, you take the—you determine the elevation of the lake at a certain fixed time—did you—or how did you determine that?

A. By precise levels run from the tidal waters to the various points on the great lakes, the elevation of these several points, with respect to mean sea level is determined. These points of which the elevation has been determined are called bench marks. By the use of a leveling instrument the difference of elevation between this bench mark and a point to be used in measuring the height of the water surface is determined. This gives, then, the elevation of the point used in making the water level observations. The distance of the water surface at any instant above or below this mark so set, and the elevation of which has been so determined, gives the deduced elevation of the water surface at that moment.

Q. Now, knowing the elevation of the lake at different times, and knowing the quantity of water which is discharged at different times, how do you proceed to determine the relation which the one bears to the other, the method of that?

A. It is found that in general the discharge is greater as the elevation of the lake from which the discharge is coming is increased, and the relation—

Q. If you will pardon me for interrupting, if you had no measurements at all, made no measurements at all, is there any principle which would be applicable in determining the relation the quantity of water which went through the river would bear to the height of the lake, the elevation of the lake?

A. You mean by "no measurements at all," do you mean the measurements of the current velocity?

Q. Measurements of current velocity, yes.

A. An approximate idea could be obtained from measurements of the characteristics of the river, that is, the cross-sectional areas at various points, and then by analogy the probable effect for that particular stream obtained.

Q. Well, go ahead with your description of your method.

A. Where did I leave off?

(Answer read, as follows:

"It is found that in general the discharge is greater as the elevation of the lake from which the discharge is coming is increased.")

A. That is, a relation exists between the elevation of the water surface in the lake above and the discharge of the river. This relation of the discharge to the elevation is expressed as an equation in which the discharge is given as a certain amount at a given elevation of the lake, and increasing a certain amount for each foot of rise in the lake.

Q. Through how many outlets does the water flow out of Lakes Michigan and Huron, so far as you know, Mr. Sabin, or so far as is known?

A. One.

Q. What is that?

A. The St. Clair River.

Q. And in addition to that, of course, there is the quantity that is diverted here in Chicago?

A. Yes, sir.

Q. Through the Drainage Canal?

A. I was speaking of it, naturally.

Q. You are speaking of the natural outlets. What is the effect of the diversion of a given quantity of water from Lake Michigan at Chicago upon the quantity of water which is discharged through the St. Clair River?

A. If a new outlet, an artificial outlet, is made in the lake, and no change is made in the natural outlet, the amount of water leaving the lake is greater at first than it would have been without the artificial outlet. The effect of this diversion through the artificial outlet will be to lower the water surface of Lake Michigan, until it is at such a level that the amount of water flowing in the natural outlet, plus the flow in the artificial outlet, is equal to what it would have been through the natural outlet alone, had no artificial outlet been made.

Q. So that, all other conditions remaining the same, is it or is it not impossible to divert a certain given quantity of water from Lake Michigan at Chicago, without affecting the level of the lake?

A. No, sir, it is not possible, if all other conditions remain the same.

Q. Are there any of the other factors which enter into the determination of the level of the lake, which would be modified by the diversion of the water at Chicago? I am speaking of precipitation, evaporation and those things?

A. No, it would have no effect on such natural phenomena.

Q. What are the elements, Mr. Sabin, that enter into the determination of the lake elevation?

A. Referring to some particular lake?

Q. Well, take Lakes Michigan and Huron.

A. The inflow from the lake above—the outflow through the outlet—and the rainfall on the lake surface, the evaporation from the lake surface and the run-off of the land area.

Q. I assume that you limit your answer to the natural state of the lake without any artificial modifications?

A. Yes.

Q. By the creation of any artificial outflow?

A. Yes, sir.

Q. If there was such an artificial outflow, that would be an additional factor which would have its effect?

A. Yes, I said the outflow through the outlet, and if another outlet were made that would make that plural.

Q. Certainly. Now, assume that the water is taken out from the lake at Chicago, and the result of the taking out of that water is, as you have said, to lower the level of the lake, so that the level of the lake is lower at a point 10 or 15 miles off the shore, what would be the fact with reference to the lowering of the level of the lake at other points and in the harbors and channels of the entire lake?

A. The mean level would be lowered the same amount throughout Lakes Michigan and Huron.

Q. That would be true with the level at the head of the St. Clair River, would it?

A. Yes, sir.

Q. Now, we are using the term "lowering," and you speak of lowering the level of the lakes. When you say that the diversion of the water through an artificial outlet at Chicago would be to lower the level, do you mean that that would be the absolute result; that is, that the level of the lake would as a matter of fact of necessity be lower than it was before the water was diverted, or do you use the term as if you meant lowering effect?

A. If other natural conditions remained the same after the opening of an artificial outlet as before, it would mean an actual lowering. The other factors, however, regulating the level of the lake might be such as to cause for a limited period an actual rise of the surface after the diversion was made.

Q. Well, for example, what?

A. For example, if through the artificial outlet a discharge of 10,000 cubic feet a second were taken, beginning at

some particular instant, and at that time the natural conditions changed so that the inflow from the drainage basin, we will say, is more than 10,000 cubic feet a second greater than it was before, under those conditions the water level would actually rise after the diversion was made, temporarily.

Q. Well, supposing we take this case, to fix what we mean by the definition of lowering: suppose it was possible for us, instead of having one set of Great Lakes, to have two sets; suppose we had two globes like this, identical in every respect, with the exception that for a given year on one of the globes no water was diverted at Chicago, and on the other of the globes a certain definite quantity was diverted at Chicago, what would be the effect of the level of the lake on the one globe as compared with the other?

A. The level of Lake Michigan on the one globe having the diversion would be lower than that on Lake Michigan on the other globe.

Q. In accordance with the amount that was diverted?

A. Yes, sir.

Q. Does that represent fairly what we mean by the term "lowering" as we speak of it in this connection?

A. I think that is a good illustration of it.

Q. I want to get it clearly here in the record because it is a term we use right along in the testimony. Can you give another illustration that would show it any more clearly?

A. Only perhaps by bringing it down to smaller areas, it may be perhaps more easily grasped. If we have a small pond with a certain outlet and a certain inlet, the outflow and inflow being so regulated that that pond remains at a constant level. If you now enlarge the outlet or make a new one, so that the amount of water flowing out is temporarily greater than it was before, while the amount flowing in remains the same, the level of the pond will fall. And to complete the illustration, when it has fallen enough so that the amount of water flowing out by the first outlet is decreased by the amount flowing out by the second or new outlet, the equilibrium will again have been established and the pond will be found at a lower level.

Q. Take now the case of Lakes Michigan and Huron, and the proposed diversion of the water here at Chicago. What is the fact with reference to the amount of water which will ultimately go out through the St. Clair River as compared with what would have gone out at that time if there had not been the diversion of the water at Chicago?

A. After the equilibrium disturbed by this new outlet has

again been assumed, the amount flowing out of the St. Clair River would be less than under the first supposition by the amount of the diversion.

Q. That is the ultimate effect?

A. Yes, sir.

Q. You use, I assume, in connection with your testimony in this matter, a term "net supply," and so that we may understand what is meant by that as it is used, I will ask you what you mean by net supply?

A. The net supply to a given lake I consider to mean the inflow to the lake from all sources less the abstraction of water from the lake from all sources, except the flow discharged out of its outlets or inlets.

Q. You say the quantity of water which is in Lakes Michigan and Huron—and in this examination when we speak of Lake Michigan I assume that Lakes Michigan and Huron are, so far as elevation is concerned, one about the same as the other, is that correct?

A. They are, yes, sir.

Q. So that it is proper when we speak of Lake Michigan to assume that it naturally applies to the whole?

A. We call it Lakes Michigan-Huron.

Q. Now, you say the quantity of water in Lakes Michigan and Huron is determined by rainfall, evaporation, absorption, the discharge through the St. Clair River and the inflow from the St. Mary's River: is there any one of those factors that enter into the determination of how much water there is in the lake which in itself is modified or affected by any diversion of the water at Chicago?

A. You mentioned the outflow of the St. Clair River; that is affected.

Q. Any except that?

A. No, none other to an appreciable extent.

Q. Is there any factor which determines the amount of water which comes into a lake which to any appreciable amount is itself affected by the diversion of the water at Chicago?

A. No, except for the amount of water which may be intercepted by the channel carrying this diversion. I mean the flow, for instance, of the Chicago River, which would have reached the lake, may under the new conditions be intercepted and go through the river channel.

Q. That is, it would make it that much less?

A. Yes, sir.

Q. It would diminish the quantity that came in?

A. Yes, sir.

Q. Is there any other factor which goes into the determination of that which you can conceive would be affected in any way at all?

A. No, sir, no appreciable effect.

Q. Is there any conceivable source of water coming into the lake which would be appreciably affected?

A. Not to my mind.

Q. Which in itself would be appreciably affected by the taking of water out at Chicago?

A. Not to my mind.

Q. Now, there have been presented already in the taking of the testimony in this case, certain charts or plats which have been marked Government's Exhibits 1, 2, 3 and 4; now, on those maps or charts certain observations have been platted. Did you have anything to do with the making of any of the observations that are platted on any one of those charts?

A. I had something to do with the observations taken on the St. Clair River in 1899, 1900, 1901 and 1902.

Q. Now, I wish you would tell us just how those observations are made, with particular reference to the manner in which the record of them is kept; who makes the record and how is it kept? Take a given observation, for instance, what is the system about making a record of that?

A. That is rather a long story. Those instruments are read in the field by an observer. Some of that work was done by myself personally, and sometimes it was done by an assistant, and the observation of the number of revolutions of the meter wheel in a certain length of time, as 100 seconds, is recorded in the book—in the note book.

Q. Is that note book kept?

A. That note book is preserved as a part of the records. By what are called rating observations, the meaning of a certain number of revolutions per second of the meter wheel for a given meter is determined, by methods familiar to all engineers. I suppose it is not necessary to go into it in reply to this question.

Q. Well, this is a law suit, with lawyers and judges; I guess you will have to go into it, Mr. Sabin. What I want, and you can be brief so we can get that point, is, we platted here certain observations and these observations are taken from records, of course, and they are official records, I assume?

A. Yes, sir.

Q. Made by government employes in the discharge of their duties as such employes, is that right?

A. Of the Lake Survey, yes, sir.

Q. And the record of those observations is kept at the office there at Detroit?

A. At the office of the United States Lake Survey.

Q. As a part of the records of the office?

A. As a part of the records of the office.

Q. And those records show the quantity of water which passes a given point at a given time, is that correct? What I want to find out is just what is platted there.

A. This plat is composed of points, each one of which is the mean of several observations of the discharge of the St. Clair River. The discharge is platted on this plat with respect to the elevation of Lake Huron. A line has been drawn on it which shows approximately the apparent change in discharge for a given change in level. That is what we call a discharge curve or a discharge line, and having the increment of discharge from such a plat, or from the equation of the line, the effect of any change in level of the lake upon the discharge may be determined.

Q. What does that diagonal line drawn across there show?

A. It purports to be a line which is the straight line most nearly according with the observations as platted.

Thereupon a recess was taken to 2 o'clock p. m. of the same day, Wednesday, April 21, 1909.

Wednesday, April 21, 1909, 2 o'clock p. m.

Parties met pursuant to adjournment.

LOUIS C. SABIN resumed the stand and testified further as follows:

Mr. Wilkerson: Q. Referring now to these plats which you had before you this morning, Mr. Sabin, I wish you would take the one that is marked Exhibit No. 1, which relates to the discharge through the St. Clair River, I think, does it not?

A. Yes, sir.

Q. I wish you would tell us whether you have seen that plat before and what you have done in connection with it?

A. I have seen a copy of it before and have examined it; I did not prepare it.

Q. What do you say as to whether that line that expresses the relation between the lake level and the volume of discharge is correctly drawn?

A. I have not checked over the platting of these points; with those points as platted, I should say that the line drawn through them fairly represents them.

Q. Assuming that that line is correctly drawn, what have you to say with reference to what is there denominated the "increment"?

A. The increment is the change of outflow for a foot change in stage; as given here is 23,800 cubic feet per second.

Q. On the basis of that chart, what would be the lowering of Lakes Michigan and Huron in inches for a diversion of 10,000 cubic feet at Chicago?

A. It would be 10,000 cubic feet divided by the increment, 23,800 cubic feet, multiplied by 12, which gives about five inches.

Q. You mean divided by 12. Is that what you said?

A. No, multiplied by 12.

Q. Multiplied by 12?

A. Yes, sir.

Q. In your opinion, how exact is that statement?

A. From my general knowledge of the discharge increment of the St. Clair River, is that what you mean?

Q. Yes.

A. I think that five inches would be a minimum amount; but I should expect it to be not less than five inches, and perhaps considerably more.

Q. Explain why do you say that?

A. Because in the work that I have done with a portion of these data, I have been led to the conclusion that the increment, when referred to Lake Huron alone, was somewhat smaller than the one that is given here.

Q. The smaller the increment, the greater the change in lake elevation, corresponding to the loss in outflow. Is that correct?

A. Yes.

Q. Why is that true?

A. A loss in depth of one foot makes a given change in outflow, which is called the increment. Now, if that increment is small, then a given diversion is a larger proportion of that increment, and therefore a larger proportion of the foot which the increment represents.

Q. Now I direct your attention to this fact, Mr. Sabin: you speak of the increment which is used as a basis of those

calculations as being probably larger than the true increment; and I direct your attention also to the fact that Mr. Wheeler, in his computation on the chart, had to recompute it, the points as there platted, and had a figure for increment which differed slightly from the increment which is there used. Can you explain to us why it is in different calculations with reference to these, there is this slight variation in the increment which is used?

A. Yes, because on the St. Clair River, the discharge at any time is a function of two quantities; the elevation of Lake Huron and the elevation of Lake Erie; and it therefore requires a larger number of observations to obtain it with the same accuracy than in the case of those streams where they have but one variable affecting the result. And the nature of the effect of Erie and Huron is such that a change, an assumed change given in deriving the equation, an assumed change in one will have an effect upon the resulting change in the other, in the effect of the other, so that, to illustrate: under certain conditions of levels in Lakes Huron and Erie, we have a certain discharge. Now, suppose that Lake Huron goes up an inch, Lake Erie remaining the same; the discharge will be increased by a certain amount.

Q. Do you mean Lake Erie or Lake St. Clair?

A. Yell, I am speaking of Lake Erie rather than Lake St. Clair, for the reason that Lake St. Clair's level is practically controlled by the levels of Lake Erie and Lake Huron. And I thought it better, therefore, in this illustration, to go to the lake that had this regulating effect.

Q. Excuse my interruption; go on with the answer.

A. As I was saying, this raise of an inch in Lake Huron would have a certain effect. Now, at another time, with Lake Huron at the same elevation, if Lake Erie went down an inch, that would also have the effect of increasing the discharge. When you have a series of observations, you have various variations in the surface of both Lake Huron and Lake Erie, but as a lowering of Lake Erie has a smaller effect than a raising of Lake Huron, in the discharge on any given day, you may mistake for the effect of a raise in Lake Erie a lowering in Lake Huron; and the variation in increment of Lake Huron, as gotten by different computers, has this variation due to this cause. And this is one of the highest ones; that is this increment shown on this plate of 23,820, is one of the highest increments. During practically the first year or two of my observations on the St. Clair River, I de-

duced an equation which showed that the increment was about 19,000, instead of 23,820.

Q. That is from a different series of observations?

A. No, that series of observation is also included in here.

Q. But other observations are added?

A. Are also added to those. I should think that the truth lay between probably 19,000 and 23,820.

Q. Without regard to the precise quantity which is to be put down as representing this increment, what do you say as to the absolute fact as to the effect of diminishing the quantity of water which flows out through the St. Clair River upon the level of Lakes Michigan and Huron; I say, without regard to the precise accuracy of the increment?

A. What effect has the flow?

Q. What do you say as to the absolute fact as to the diminishing of the quantity of water which goes out through the St. Clair River upon the level of Lakes Michigan and Huron, the relation between those two?

A. Well, certainly an increase in discharge of the St. Clair River would have a tendency to lower the level of Lake Michigan. Is that your question?

Q. My question is as to the absolute fact as to the relation between the level of Lakes Michigan and Huron and the discharge from the St. Clair River, as to there being such a relation.

A. Yes, there is no doubt at all about that.

Q. I mean as to the absolute fact?

A. No, sir, no doubt at all about that.

Q. And as to the amount of the change, do you think the truth is some place between the low increment, to which you have referred here, and the higher increment which is used on the charts that have been produced by the government?

A. Yes.

Q. And if the lower increment be used, would the effect be greater or less; that is, would the lowering of the level be greater or less?

A. The effect of a given diversion would be greater with a small increment.

Q. Having in mind your own deductions and your own experience, what would you say as to the limits between which the effect of a diversion of 10,000 cubic feet at Chicago would fall, in inches?

A. Between five inches and seven and one-half inches.

Q. Can you give us any information as to the percentage, as to what percentage of the lowering in Lake Michigan the

water in St. Mary's River at the foot of the locks would be lowered?

A. I can't give a definite answer to that question for the conditions prevailing at present, because last August the conditions of outflow of the St. Mary's River were quite seriously disturbed by the opening of a new channel. Previous to about 1890 the work that had been done in the improvement of the lower St. Mary's River was quite small. And I have had occasion to go into that question for that period, and the effect for that period, up to 1890, would be about 47 per cent. That is, that a change in the elevation of Lake Huron would change the elevation of the St. Mary's River at the foot of the locks 47 per cent. as much; that is, one foot of Lake Huron would change the St. Mary's River .47 of a foot. Since that time, due to the improvements in the St. Mary's River, the slope, which previous to that time had had a mean value of about 2.1 feet, has been reduced by from a foot to a foot and two-tenths, I should say, by the new channels opened and the improvements in the channels, and the slope being less for a given elevation of Lake Huron, and a given discharge from Lake Superior, the effect would be greater; how much greater it is difficult to say, bearing in mind that 47 per cent. was the figure before 1890, and that the slope has been changed over a foot; I should say that perhaps 60 to 75 per cent. of the loss would be felt.

Q. Within what limits, then, if you are going to get the effect, could you put the fact as to that, so as to be absolutely sure that you were within the truth?

A. There would be no question in my mind about the lower limit being above 47, and the upper limit would be below 100; and I would not care to go any further.

Q. The point I wanted to bring out was, would there be any doubt, is there any doubt that there is some substantial effect, first?

A. No. Those limits give substantially the effect; 47 per cent. is the lower and 100 the higher; that is not absurd.

Q. And as to the lower limit, you would say that was not open to doubt?

A. No, not open to doubt, any more than any other engineering data are.

Q. I suppose this is true, if I may put the question in this form, isn't it, Mr. Sabin, that without regard to the precise amount of the effect, there are elementary laws or

principles which control, in a situation of that kind, which make it absolutely certain that there would be some effect?

A. Yes, with a knowledge of the natural conditions existing; there is no doubt of it.

Q. What is the mean fall at the present time between the water at the foot of the lock and Lake Huron?

A. The recent improvements have not been completed long enough to determine that. The mean fall for the seven months of navigation from 1871 to 1890 was 2.1 feet. That fall is affected by the elevation of Lake Superior, or rather by the discharge of the St. Mary's River and by the elevation of Lake Huron; and it varies considerably. Taking the mean for seven months, considering only the mean for each year for the seven months of navigation from May to November, it has varied from a foot and a half to 2.9 feet, roughly.

Q. You have given us your answer now with reference to the lowering of the water at the foot of the locks. Are you prepared to make any statement as to the effect at the critical points in the river?

A. Only within rather wide limits.

Q. Well, first, as to there being some substantial effect?

A. There would be substantial effects, and the character of the river is such that the percentage of a given change on Lake Huron, the percentage of that effect, starting out, whatever it may be at the locks, would increase from the locks down until it became 100 per cent. at the mouth of the river.

Q. So if 47 per cent. were taken as the lowest limit at the locks, the effect at those different critical points would be expressed by percentages larger than that?

A. Yes.

Q. Increasing as you went down the river?

A. Yes.

Q. Which would in the case of most of them be in excess of 50 per cent.?

A. Yes.

Q. And as to those that were further down the river, very considerably in excess of that?

Question objected to by counsel for the defendant, on the ground the counsel is leading the witness and testifying.

A. A very considerable extent.

Q. If Lakes Huron and Michigan are lowered a known

amount, and Lake Erie a known amount, what would be the effect in the Detroit River, Lake St. Clair and the St. Clair River?

A. They will also be lowered.

Q. Can you make any statement as to the amount, or have you given consideration to that?

A. I should expect that the level of St. Clair would be affected by practically the mean of the two lowerings; that is, the mean of the lowering for Lakes Michigan and Huron, and the lowering of Lake Erie.

Q. What would be the effect of the diversion of water from the lake at Chicago upon the outflow of the Niagara and St. Lawrence Rivers, and why?

A. It will decrease the outflow of those rivers by the amount diverted at the Chicago Drainage Canal, practically undiminished.

Q. Now, with reference to these three other charts that I showed you this morning, Mr. Sabin, I wish you would take each one of those charts and tell us what examination you have made of them; what each one represents, and whether in your opinion the result as stated in the form of that scale at the left hand side is correct?

Mr. Williams: He is not testifying now to the correctness of the observations or the correctness of the platting of them.

Mr. Wilkerson: Q. I understand, with the exception of the observations on Lake St. Clair, you did not make any of the observations that are represented on the plat?

A. No, sir.

Q. You have testified about the only one of the plats as to which you made observations?

A. Yes, sir.

Q. As to the others you did not make the observations yourself?

A. No, sir.

Q. Nor did you plat the observations?

A. Not on this, no, sir.

Q. What you have done is as an engineer to make an examination of the methods of reaching the result. Is that what you have done?

A. Yes, sir, I have gone over that, not with respect to these plats, because I have not gone over that matter since that time, further than to see that this agreed approximately with the data which I had checked over and satisfied myself about before.

Q. Have you gone over the method which has been there used of reaching this result?

A. Yes, sir.

Q. As based upon observations of lake level and outflow?

A. Yes. That is a proper method.

Q. I wish as an engineer you would give us for the record here a brief explanation of the method that has been used on these charts.

A. Exhibit No. 2 has a number of points plotted, purporting to give the discharge measured a certain heights of water surface in the St. Lawrence River at Ogdensburg. Through these observations a line has been drawn which fairly represents the observations as plotted. This line may be used to indicate the change in discharge of the St. Lawrence River for a given change in level at Ogdensburg, or to show for a given change in discharge at Ogdensburg what the resulting change in level would be. This line shows a change of outflow for one foot change in stage, 28,870 cubic feet per second.

Q. Now, does the same general explanation which you have made with reference to that apply to the others?

A. It does.

Q. Assuming the accuracy of the observations which have been platted, and assuming the accuracy of the platting of those observations, what have you to say as to the correctness of the result which has been reached, based upon the observations as platted?

A. I think that line fairly represents the observations plotted. That is all that can be said, I think.

Q. Would you say, if the observations were correctly made, and if they are correctly platted, that the result is substanitally correct?

A. Yes, sir.

Q. And by that I refer to the result in the lowering of the lake level, as expressed there on the scale at the left of the chart?

A. That would refer to the St. Lawrence River, and the lowering of the river at Ogdensburg.

Q. That is as to that chart?

A. Yes. You said "lake." It would show the lowering of the river at Ogdensburg.

Q. I was correct in using the word "lake," with the exception of the one chart where it is in the river?

A. Yes, sir.

Q. So that, if water is diverted at Chicago, will Lake Erie be lowered?

A. Yes, sir.

Q. And what will be the effect upon the Niagara River?

A. That will also be lowered.

Q. And what about the effect on Lake Ontario?

A. That will also be lowered.

Q. Now, how much in each case?

Mr. Williams: Do you mean in percentages, or given a certain amout of diversion?

Mr. Wilkerson: I am speaking on the basis of 10,000 cubic feet per second, and I am assuming—and I ask you to correct me if I am wrong in it—that if we have the amount of the lowering for 10,000 cubic feet, for a smaller amount or a larger amount, it is proportionately smaller or greater. Is that correct?

A. It is.

Q. So we will take a diversion of 10,000 cubic feet for the purpose of shortening the record, and limit the answers to that, with the understanding that the lowering for a different diversion can be reached by taking a proportion thereof?

A. The effect on Lake Erie will be five and one-half inches, forty-six hundredths of a foot. The lowering at Ogdensburg four and one-quarter inches. That answers the question, does it not?

Q. Have you given them all?

A. Lake Erie and St. Lawrence River.

Mr. Williams: Lake Ontario you did not give.

Mr. Wilkerson: Did you give Lake Ontario?

A. Lake Ontario would be very slightly greater than the St. Lawrence River at Ogdensburg; practically the same, but very slightly greater.

Q. With regard to the accuracy of those figures, as to their being larger or smaller than what is probably the fact, what do you say about that?

A. I think that the figures for Lake Erie and Lake Ontario are very good; roughly, I should say not over half an inch in error, as given.

Q. That is for a diversion of 10,000 cubic feet?

A. That is for a diversion of 10,000 cubic feet a second.

Q. How do the recent measurements of the Niagara River agree with the measurements made by the Deep Waterways Commission in 1897 and 1898?

A. They agree quite well; when I speak of agreement, the

same conditions are not always renewed—do not always occur again.

Q. With regard to the increment of discharge?

A. I have never worked out the increment from the measurements of the Deep Waterways Board alone.

Q. How about the comparison of the recent measurements with those by Quintus in 1891 and 1892?

A. I could not testify to that.

Q. Coming back now to the St. Clair River, what is the season of navigation in the St. Clair River? I don't mean whether there may be a few boats a month, but using that word in the generally accepted meaning that is given to it?

A. Usually during January, February and March, there is very litle navigation on the St. Clair River.

Q. Now, in connection with the St. Clair River, there is what is known as ice retardation, is there?

A. Yes, sir.

Q. What do you mean by that?

A. The presence of ice in any channel cuts down the cross-section of flow and reduces the amount flowing as compared with the same conditions without ice, I should say.

Q. When does this ice effect begin?

A. It varies from—in different years. There are no accurate records that are available except for the last few years, with this exception, that a disturbance in the relative fall in St. Clair River and Detroit River indicates the presence of ice is one or the other. But I should say retardation might be of such an effect in both at the same time that no disturbance of the relative falls would be noticed, and aside from that data I say there are none that I know of, that I recall at least at the present, previous to about 1899, when the gauges were established at the head of the St. Clair River. Since that time one can infer with considerable certainty whether there were ice retardations in the St. Clair River. Have I answered the question?

(Last question read.)

A. In those last few years, there are only three which show a marked effect in December. And there is but one or two that show any marked effect in May.

Q. How long does that ice effect continue?

A. Different lengths of time in different years.

Q. How about April?

A. April, there is quite frequently an ice effect, a retarding effect from ice in April.

Q. How about May?

A. Seldom, as I said.

Q. And is some time in May as late as it is ever noticeable?

A. Yes, and I think it is never noticeable in November; usually not in December.

Q. Now, what is the effect of this ice retardation upon the level of Lakes Michigan and Huron?

A. As it holds the discharge to a lower value than it would have without the ice, it has the effect, the immediate effect, of raising the level of the lake.

Q. Is there anything in this ice effect about which you have been testifying that in any way neutralizes or overcomes the lowering tendency from the diversion of water at Chicago?

A. No, I can see that it would have no effect on that.

Q. Would it have any relation on that whatever, that is, so far as the lowering tendency of the diversion of the water at Chicago is concerned, is there any conceivable relation?

A. No, I think not.

Q. By that you mean you can see none?

A. I can see none.

Q. By that answer you mean this lowering tendency here would go on even though—

A. Yes, sir; that, I think, was in your question.

Q. —even though there was the other tendency, on account of ice in the St. Clair River? I wanted to make it clear, that is all. What information are you able to give us, Mr. Sabin, as to whether the St. Clair River is changing its regimen?

A. I don't know what it has been doing in recent years other than the reports of others. I made an investigation of it about 1900, 1902, and concluded that there was no reason to suspect that there had been any appreciable change in regimen as far back as the records went, of the depth of the channel.

Q. Well, suppose there was some small scouring, what would be the effect?

A. It would change the value of the increment of discharge for a given change in stage. The most likely effect would be that it would increase that increment; making the change in discharge for a given change in stage greater.

Q. I assume that there is some change in the regimen of the St. Clair River from time to time, at a given time, at a

given fixed time. Is there anything in that which neutralizes or overcomes in any way the lowering tendency of the diversion of water at Chicago?

A. No, it does not neutralize or overcome that lowering tendency, but may change its amount.

Q. Is or is not that a factor that is analogous to the ice effect, about which you have testified?

A. Yes, with this exception, that if such a change in regimen were made as to change the value of the increment, then the ultimate effect of a given diversion at Chicago would be different with that new increment than it is under the present conditions, with the present increment.

Q. But there would be?

A. The same tendency would be there to lower.

Q. There would be the same original diversion, which would be translated into effect on the basis of the new increment?

A. Yes, sir.

Q. Well, has there been any such change or do you think any such change possible, that would result in such a change in the increment as to materially affect the lowering tendency of the diversion at Chicago?

A. I should dislike to testify about what is going to happen, but judging from what has happened in the last 50 years, I should not expect—

Q. Assuming that the laws of nature remain constant, for the purpose of your answer, and that there is no such thing as an earthquake or other dire disturbance?

A. In the last 50 years there has been no practical change in the regimen of the upper St. Clair, so far as I know.

Q. So that, so far as that factor is concerned, could you say that increment would remain substantially unaffected from time to time?

A. I think I have practically said that.

Q. I wanted to be clear on that.

A. Yes, sir.

Q. You have given your time for a number of years pretty continuously to the study of the lakes, have you, Mr. Sabin?

A. For certain periods during the last few years, yes, not continuously.

Q. Do you know, or did you ever hear of any outflow from Lakes Michigan and Huron, except through the St. Clair River and what water is diverted at Chicago, substantial diversion?

A. No, sir.

Q. Well, what other diversions do you know of? Is there any other?

A. Nothing, I think, that could be called a diversion, nothing that could be called an outflow.

Q. Anything that would have an appreciable effect upon the quantity of water in the lake?

A. Well, the effects of rainfall and evaporation, but nothing in the nature of outflow.

Q. Outflow?

A. Yes.

Q. I was speaking of the outflow, that is, of the ways in which water gets out of the lake. There is some water, it is said, seeps into the lake, and it has been assumed, or I suppose it may be assumed, that some water comes in in the shape of subterranean streams or springs. Now, what would be the relation of that condition to the level of the lake?

A. I do not think, in the first place, that such an assumption is warranted.

Q. Well, give us your view of that. I would like to have your opinion, based upon your experience and your study of lake conditions, with reference to that.

A. I can see no reason for anticipating that there is any large flow into the lake or out of the lake by underground streams. If there were such streams its effect upon the ultimate effect of the diversion would be practically nil.

Q. From the very nature of things where does most of the water that gets into the lake come from?

A. It comes from streams flowing in along on the surface, streams flowing into the lake and on the surface of the ground, the rainfall, representing the rainfall on the drainage basin, and there should be added to that, perhaps, the rainfall on the lake surface, if that is not included.

Q. Well, if there was some water coming into the lake through subterranean streams, is there anything in that which there is not in the water which comes in on the surface which would counteract or neutralize the lowering tendency of the diversion of water at Chicago?

A. No, sir; nothing.

Q. There has been some reference, Mr. Sabin—I don't know whether it has been in your testimony or not, but in connection with this matter—to inconsistencies in the outflow value of the St. Clair, Niagara and St. Lawrence Rivers;

what do you know about that, and as to there being any that cannot be accounted for by ice retardation?

A. There are no inconsistencies so far as I am aware of that cannot be accounted for.

Q. Is that the result of your observation and study of this matter?

A. Yes, sir.

Q. Have you had occasion in your investigation of these questions to give consideration to data regarding evaporation and precipitation?

A. I have done a little work along that line, not very much.

Q. Have you any information as to the manner in which these statistics are collected, as to the number of observations, and as to their frequency, as to the amount of territory which is covered?

A. Yes, sir; I think that is all a matter of record, as those observations are made by the weather bureau, the observations for precipitation.

Q. It being a matter of record, it is a matter which has been brought to your attention?

A. Yes, sir.

Q. And which you have considered?

A. Yes, sir.

Q. Have you given consideration to them with a view to forming an opinion as to the degree of accuracy with which they indicate the given result?

A. In a general way, yes.

Q. Now, having that in mind, what would be your view of the propriety of using those particular data in a computation, the attempt of which was to detect the presence of absence of the effect which was produced on the lakes by the diversion of water at Chicago since 1900?

A. To my mind the character of the data which we have as to rainfall, and particularly as to evaporation, is such that it does not compare with the accuracy with which we know the outflow of the lakes, and the effect of a diversion of water can be obtained from our knowledge of the law of outflow. I should think it would be very poor engineering to attempt to combat information obtained from outflow observations with a computation which rested upon the observations for evaporation and rainfall. Is that what you wanted?

Q. Yes. Now go along that line a little further, and compare for us, if you will, the accuracy with which the outflow

observations are made and the accuracy with which these statistics about evaporation and precipitation are obtained. Let me add to that question: is there anything in the very nature of things which makes it possible to get a high degree of accuracy in one case which you cannot, from the nature of things, get in the other?

A. I can only answer that in a general way; that the information regarding the rainfall is—that the observations at any given place are subject to a considerable error, and the stations are not sufficiently distributed to give an accurate result, accurate knowledge of the amount of water falling on the lake basins, and the information regarding evaporation is in still worse shape.

Q. Now, as to those observations with regards to outflow, how about the frequency of the observations and the amount of space that is covered and their limits that make possible or impossible the obtaining of a high degree of accuracy?

A. I think that the outflow at any given time, at any given lake stage, can be determined with a reasonable number of observations within something like 5 per cent., I should say. The determination of the law of discharge, as related to the lake level, cannot be determined with that accuracy, but the errors in these determinations are much smaller, in my opinion, than those which attach to the data concerning rainfall and evaporation.

Q. I think you said a little farther back in your testimony, Mr. Sabin, that at the outside you regarded these scales expressing the loss in level, loss in lake level, at a diversion of 10,000 cubic feet at Chicago, as within half an inch?

A. For Lake Erie and Lake Ontario?

Q. Yes.

A. Yes, sir.

Q. As to Lakes Huron and Michigan, you may state the figures, from your knowledge and information, so formed.

A. I should think the upper limit was perhaps seven and one-half inches.

Q. Why do you say that maximum figure is seven and one-half, Mr. Sabin?

A. That is merely a matter of judgment, from my investigation of the data.

Q. Have you had occasion to give consideration to the subject of navigation of the lakes, the use of boats and vessels on the lakes?

A. Yes, sir.

Q. To what extent have you had occasion to study and observe that?

A. I have been in charge, local charge, of the locks at Sault Ste. Marie, and I have been more or less familiar with the operations of the shipping interests.

Q. Very well. Now, bearing in mind the fact that the lakes change in their stage from year to year, and that at times the lake surface is disturbed on account of wind and storm, I will put to you the question whether or not the lowering of the level of Lakes Michigan and Huron to the extent of two or three or four inches has any appreciable or material effect upon navigation in the harbors and channels of the lakes?

Mr. Williams: I object to that, to the form, as calling for a conclusion and not for the facts—

Mr. Wilkerson: I will accept the amendment of counsel, and have you give us the fact as to the effect of the lowering of the lake by two or three or four inches, upon nagivation.

A. It requires the vessels to load accordingly. There are certain places in the lake system where certain vessels are loading as heavily as the water level will permit.

Q. As to the number of vessels which could carry heavier loads than they do, if these channels or critical points in the lake were deeper, what have you to say about that?

A. In 1907 there were 360 boats passing St. Mary's Falls Canal that were capable of loading to 19 feet or over. The amount of freight carried through the canal by these boats in 1907 was about 49,000,000 tons.

Q. Now, what determines the depth to which those large boats can be loaded?

A. Those boats which come from or go to Lake Superior are governed by the amount of water at the lower end of the Poe Lock.

Q. Have the levels of Lakes Michigan and Huron anything to do with that?

A. Yes, sir; as already testified to under another question, the effect of Lakes Michigan and Huron lowering is felt at that point.

Q. Have you any figures which show the number of boats that are capable of loading to 20 and 21 feet, based upon your observations and study?

A. Of the boats passing the St. Mary's Falls Canal in 1907, there were 227 that were capable of loading to 20 feet and 133 capable of loading to 21 feet or over.

Q. How deep could they load at that time?

A. The available draft varied from about—it was about 19 feet 9 inches, and from that—I think from memory it was 19 feet 6 to 20 feet, and about 43,000,000 tons of freight were carried in boats which were limited by the draft in the lower levels of the locks.

Q. You send out instructions or information as to the depth to which boats can load?

A. Yes, sir; and we post that information for the information of vessel masters and shippers.

Q. How much do you allow between the bottom of the boat, do you allow any space in there?

A. No, not ordinarily. The water levels vary from day to day, and we try to give in those notices the mean drafts that they will find on the Poe Lock floor.

Q. Well, suppose the level of the lock there, the level of the water there at the canal is lowered, what effect has that on the load which the boat can carry?

A. That depends upon the size of the boat.

Q. Have you any figures there that would indicate the effect of this lowering on commerce as it is now carried on?

A. Yes.

Q. If you have that I will ask you to refer to your notes and give us the exact figures on that. Are those figures on the basis of the lowering of an inch?

A. Yes.

Q. All right. Assume, now, the level of the lake is lowered an inch, so that you can draw that much water in the locks.

A. For the larger class of boats an inch of draft means from 80 to 85 tons of freight, so that from an inch change in the draft the load of the boat would be changed by 80 or 85 tons.

Q. Have you figured out what the loss of an inch would be to commerce on the basis as it is now carried on, and taking into consideration the boats that are now engaged in this trade?

A. No, I don't remember that I have; I think not.

Q. I think, though, you have given us the data from which we could make the computation ourselves, haven't you? You have given the number of boats and you have given the loss in tonnage?

A. I think the question of the loss of tonnage, I have given that for each inch of change in draft.

Q. So all we need to know, then, would be the number of trips?

A. The number of trips?

Q. About how many trips would one of those big boats make in a season?

A. I think about 20 trips.

Mr. Williams: You are testifying now from your own knowledge, and not from something that somebody has told you or reported.

Mr. Wilkerson: Well, he is up at the Sault.

A. Yes, from information as collected at the lock.

Mr. Williams: Q. It is your personal information and not information given to you by bulletins?

A. No, it is not given to me by bulletins, but it is not what I have personally collected.

Mr. Wilkerson: Q. Is it information which is collected from a record which is made under your supervision?

A. Yes, sir.

Mr. Williams: I object to his testifying from it.

Mr. Wilkerson: Q. Answer the question.

Mr. Williams: On the ground that it does not purport to be information which is the result of his own personal information, but as a result of work done by others.

Mr. Wilkerson: Q. How are those records compiled, Mr. Sabin?

A. Each vessel that passes the locks is reported by the captain as to her tonnage, freight carried, ports of hail and destination, and this information is kept and tabulated in the office.

Q. Can a boat go through the lock without giving that report?

A. No, sir; not ordinarily. I think we may lose two or three in a season until they come on the second trip.

Q. What is done with those reports?

A. The information is tabulated and published in the form of statistical reports of lake commerce, covering in considerable detail the amount of freight carried, the number of boats of different sizes and so forth.

Q. Have you that report with you?

A. That is a copy of it. (Handing document to counsel.)

Mr. Williams: Instead of asking the witness the questions you have, I haven't any objection to your introducing that report that he is testifying from.

Mr. Wilkerson: Very well.

Q. What you have stated with reference to the number of vessels going through is based on this report, is it, Mr. Sabin?

A. No, it could not be obtained from that report, but it was obtained from the data from which that report was obtained.

Q. I see.

A. The information which I gave was based upon the records for the entire season of 1907.

Q. Yes.

A. And they are voluminous records.

Q. Could you get from this report which you have produced the facts with reference to the number of times any given vessel made a trip?

A. No, sir.

Q. You would have to go to the—

A. Yes, sir.

Q. —reports from which this book is compiled?

A. Yes.

Mr. Wilkerson: This book which Mr. Sabin has produced may be marked for identification as an exhibit of this date, so that we will have this book identified in case that either side wants to refer to it or offer it hereafter. It may be, when we get through, we will not want to encumber the record with it, so I will not offer it in evidence, thinking perhaps maybe we may be able to make some agreement as to what it shows.

Mr. Williams: Is that the 1908 report or the 1907?

A. 1907.

Mr. Wilkerson: Mark it as Statistical Report of Lake Commerce Exhibit of this date.

Whereupon said book was marked as Statistical Report of Lake Commerce of 4/21/09.

Mr. Williams: Does that report show the tonnage of the vessels, or the number of tons carried on their different trips?

A. Both, in a collective way.

Q. In that report?

A. Yes, sir; not the individual instances.

Mr Wilkerson: What do you know, Mr. Sabin, as to the dimensions of the largest freight carriers now engaged in commerce traversing the waters below Lake Superior?

A. The L. S. De Graff has a length of 605½ feet over all, and 60 feet beam. She has carried a cargo of 13,638 tons.

Q. Any considerable number of those large boats engaged in commerce now?

A. Yes, a great many.

Q. What is the tendency in the construction of those boats?

A. Most of the boats that are being built now are what may be called the larger class, although not all of them by any means of that size. The tendency is to increase the average size of the boats. That is a part of the data in that report that you have just made an exhibit.

Q. What about the tendency to build boats so large that they cannot be loaded to the limit now, and which would be affected in the load which they would carry by the lowering of the water in these channels?

A. We have just now an available draft of 18 feet 3 inches over the Poe Lock, through the Poe Lock, and in 1907 there were 360 boats that could draw 19 feet or more. Those 360 boats carried 49,000,000 tons of freight.

Mr. Williams: You testified to that before, Mr. Sabin.

Mr. Wilkerson: Yes.

A. The question was practically repeated.

Mr. Williams: He asked you about the tendency now.

Mr. Wilkerson: Q. I say, is it the tendency to build boats of that class now, so that they are becoming more and more numerous all the time?

A. Yes.

Q. And they cannot be loaded to the limit because of the condition of the lakes at these critical points?

A. Yes, sir.

Q. And the boats which would be affected by a lowering of from an inch, the lowering of the lake?

A. Yes, sir.

Mr. Wilkerson: You may cross-examine Mr. Sabin. It may be that I have overlooked a question. If so, I will put it in re-direct as though it was direct examination.

Mr. Williams: That is all right.

Cross-Examination by Mr. Williams.

Q. Mr. Sabin, are you familiar with this bulletin No. 18 of the War Department Corps of Engineers? (Handing book to witness.)

A. No, I am not familiar with it; I have seen it.

Q. On page 259 of that bulletin, referring to the Detroit River, occurs this statement: "During the lowest water of the season of 1907, except for temporary storms, a draft of 19 feet could be carried through the river, the place of lowest depth being at Lime Kiln Crossing, near the mouth of the river." Do you know how long that condition has existed?

A. No, sir.

Q. That is a greater depth by how much than that provided for during the year 1907 at the Poe lock?

A. The depth of water in the Poe lock in 1907 varied from 19.5 to 20.8.

Q. During the entire year?

A. During the season of navigation, April to December.

Q. What was the situation there during the year 1908, what was the depths?

A. I haven't those figures with me.

Q. What is the present available depth?

A. Eighteen feet three inches.

Q. How long has that depth been the available depth?

A. About ten days or two weeks.

Q. Taking up the chart or plate—

Mr. Wilkerson: Will you pardon me?

Q. Do you have what is known as low water days?

A. Oh, yes.

Q. What do you mean by that?

A. The water fluctuates, not only daily, but hourly and monthly. The water level at the lower end of the lock changes from month to month as is shown on the exhibit just put in evidence or identified. The water level is usually low in April and May and high in July, August and September, at the foot of the locks, so that this 18 feet three inches probably will not hold very long.

Q. You are giving the monthly means, are you?

A. Yes, sir; I was giving the monthly means when I read them off as to the variation, those are the means of the month. Of course, that is not the maximum variation by any means.

Mr. Williams: Q. Right on this very question propounded by Mr. Wilkerson, and in answer to it, you say that the height of the water there varies sometimes hourly and sometimes daily?

A. Yes, sir.

Q. What are those variations caused by?

A. The short time variations, those rapid variations, are caused principally by barometer and wind.

Q. And how great a variation would you consider as not being unusual, resulting from such causes?

A. In how long a time?

Q. Well, say in 24 hours?

A. During the summer season about two or three inches.

Q. Have you known of variations exceeding two or three inches, occurring within a period of say 24 hours, resulting from barometric and wind causes?

A. Yes.

Q. How great a variation have you seen within that time?

A. Well, certainly six inches; I would not say how much more.

Q. Would you say that you had ever seen a greater variation than six inches?

A. No, I would not say that I had.

Q. And within how short a time have you seen a variation of six inches?

A. My recollection of the times that I have seen those fluctuations on the lower St. Marys River are not sufficiently exact for me to go into them.

Q. How near the bottom of the channel does the ship's bottom pass at the locks, ordinarily?

A. I think that that question is a little indefinite. Not ordinarily. Some of the boats drag on the bottom as they go out; some of them may have an inch under them and some may have two or three feet.

Q. Do you give any instructions to the vessel owners as to the amount of draught they may carry through the locks?

A. We give them the amount of available draught as near as we can,—the amount of water there is in the lock. We give them that information.

Q. And you supplement that information by a statement of the draught they will be permitted to load to?

A. They draw all the water there is in the lock.

Q. And there are no instructions given, then, only information as to the amount of water in the lock?

A. No, sir.

Q. Now, passing through the St. Clair River, or the Detroit River, do you know to what depth the vessels load, how near the bottom, at the critical points?

A. It is my understanding that they touch the bottom in going through. They certainly did in the St. Marys River before it was improved.

Q. You made or had charge of the observations in the St.

Clair River, which in part form the foundation for the Exhibit No. 1?

A. Yes, sir.

Q. When were those observations made?

A. In 1899, 1900, 1901 and 1902.

Q. Were those observations and the results thereof published?

A. Yes, sir.

Q. With a report by yourself in the report of the chief of engineers?

A. Yes, sir.

Q. The gauge heights and elevations of water surfaces shown in your reports published in Appendix EEE, are they subject to correction? This is 1902?

A. The water levels that are found in that report are based on the determination of elevations of bench marks made a good many years ago. In 1903 the lake survey completed a new determination of the difference in levels between these bench marks and the sea level.

Q. Well, now, then, assuming that the several gauges, heights and elevations of water surfaces mentioned in these reports are subject to correction due to a more accurate determination of bench marks by the levels known as the levels of 1903, I will ask you whether the data presented on pages 2830, 31, 32, 33, 34, 35, 36 and 37 of Appendix EEE of the annual report of the Chief of Engineers for 1902 are correct representations of your observations of the discharge on the St. Clair River as shown by these reports during the years 1899, 1900 and 1901?

A. Yes, so far as they purport to be.

Q. Will you explain what you mean by that last sentence?

A. Why, that there are some things in those tables which are not a matter of observation.

Q. For instance?

A. For instance, table No. 7, on page 2837, is one that I notice.

Q. Yes?

A. The effects of ice there are not measured effects. They are from the application of a formula.

Q. Then we will exclude table No. 7 and refer only to the first six tables, and limit the question to page 2836; that is, I think, the last page,—from 2830 to 2836, inclusive.

A. They, I believe, are a correct representation of the

data as obtained by me, and the deductions which I made from them.

Q. Now, then, would you say the same as to pages 2811 and 2812 of Appendix FFF of the annual report of the Chief of Engineers for 1903, referring to observations for the year 1902?

A. No, I don't think that I prepared that table.

Q. Were the results of your observations for the year 1902 published?

A. I think all I made were in this previous report.

Q. Now, Mr. Sabin, the data concerning which you have testified as being the results of your own observation, and shown in Appendix EEE, are those observations and the data contained in that report subject to any other corrections than those that I suggested in the former question, than the corrections due to the more accurate determinations of the bench marks?

A. No, except as appears in the report.

Q. Now, will you look at the map and the cross-section on plate 1, opposite page 5400 of Appendix III and KKK of the annual report of the Chief of Engineers for 1900, and state whether or not that plate was prepared under your direction and supervision?

A. Yes, sir, it was.

Q. And is it correct, and does it correctly represent the matters purporting to be shown thereon?

A. It was compiled from the best data available at the time.

Q. And to the best of your knowledge and belief it is as correct as could have been made from that data?

A. Yes, sir.

Q. Have you any reason to believe that the conditions existing at the time that that plate,—cross-section,—was prepared, were any different from what they are now?

A. There have probably been some slight changes along the banks.

Q. Well, confine it, then, to the time that it was prepared. Have you reason to believe that any of the facts purporting to be shown on that plate were different from the actual facts?

A. No, sir.

Mr. Williams: Now, Mr. Wilkerson, I would like to have marked for identification, or else have it understood, that

those pages from the report of the Chief Engineer for the year 1902 may be offered in evidence later on.

Mr. Wilkerson: You can give the numbers of the pages to the reporter, and the numbers of the plates that have been previously identified by the witness, and those pages to which you have referred may be used for the purpose of impeachment or parol testimony, so far as he has identified them.

Mr. Williams: Q. Mr. Sabin, at how many points in the measured cross-section of the St. Clair River did you use the current meter in making your observations?

A. The section was divided into, I think, 21 partial areas.

Q. At what width of the river was it divided into that many areas?

A. The section is a little over 2100 feet in width, and then observations for discharge were taken 100 feet apart. The section was divided into 21 partial areas with a discharge station in the center of each, with the exception of the two end areas, the width of which varied with the water stage. Then within each of those partial areas the meters were placed at different points,—that is, not simply at one point in that 100 feet.

Q. You mean different points horizontally?

A. Both the vertical and transverse curves were observed for, but more particularly the vertical curve, that is, the change in velocity from the surface to the bottom.

Q. How many meters did you use?

A. I think 11 at one time was the most that we used, but ordinarily in taking the discharge, only two meters at a time.

Q. Well, now, in making the measurement at a given point, how did you arrange your meters? Were they suspended in the water one above the other?

A. They were, for getting what I have referred to as the vertical curve, that is, showing the changes in velocity from the surface to the bottom.

Q. And in such case how many meters would be used?

A. We used from 6 to 11 meters for that purpose.

Q. How many of these meters, or were they all, rated?

A. Yes, sir, they were all rated.

Q. How many of those meters that were used there were direction meters?

A. That information is given in the report; I can only get it from that.

Q. Is that in that same report that you have just referred to?

A. Yes.

Q. Will you give the page?

A. It is about 5369, for 1900; there is a description of the method of getting the vertical curves.

Q. How long a time was consumed in getting the vertical curve at any given point?

A. Station 1 was occupied three days in making observations, and there were six sets, that is, six settings of the meter for that, and 11 curves were observed, and in the stations further out usually more than that, but from three to four days' occupation; that was not continuous. I don't mean eight hours a day continuously, but they were occupied on that many different days, so that the vertical curve was obtained, that is, this relation of change of velocity was obtained under several different conditions.

Q. And what was the total length of time required to make a single measurement of the discharge of the whole river?

A. I think we took from two to four discharge measurements, running across the river two to four times in one working day. That is my recollection of it. That shows in the table which I have identified, the number of discharges that were measured on any given day.

Q. Ten hours or eight or sixteen?

A. Well, about ten, probably.

Q. Will you give us your opinion as to the degree of accuracy that is secured by the use of these meters, the percentage?

A. In order to make my answer to that intelligible I think I should know a little more definitely just what you have in mind, whether you mean under the conditions existing on one day, how close did we know the discharge when we measured it on that day,—is that what you have in mind?

Q. Yes.

A. I should say somewhere in the neighborhood of 5 per cent.

Q. You mean by that that the actual amount of water flowing might be either 5 per cent. less or 5 per cent. more than there shown?

A. For that one observation.

Q. For that one observation?

A. Yes, sir.

Q. Within a range, then, of practically 10 per cent.?

A. Yes, that is a rough approximation of my idea of the accuracy of it.

Q. What method did you use to determine the exact point on the line which was the water surface or the vertical plane of the cross section?

A. Horizontally?

Q. Where you had an upper line of a vertical plane?

A. The intersection of the cross section with the water surface of the river?

Q. Yes.

A. And how we located ourselves across the river, transverse to the river, along the line?

Q. Along the upper line, yes.

A. By the use of ranges on shore.

Q. How nearly accurate would you say that those determinations of positions were?

A. Within probably five feet.

Q. What precautions did you take, or what means did you employ to make sure that none of your determinations were vitiated by the shifting currents, and the changes of lake elevation due to the wind and eddies?

A. We measured the velocity of the current as it actually existed at the time we were there. There was no way of stopping the wind or the eddies.

Q. But those measurements you were making were later to be used in connection with the level of the lake in order to ascertain the relation one to the other?

A. Yes, sir.

Q. Now, then, did you have any means of making sure that that relation could not be ascertained because of temporary fluctuations in the lake level during the time of your observations?

A. The lake level was taken continuously during the time of the observations. We knew the lake level at each observation.

Q. But if the lake level rose suddenly by reason of some temporary cause, such as a wind, and remained in that position for a few hours, did you take that as an ordinary stage of the lake, as unaffected by that temporary condition, in ascertaining the relation between the two, the discharge and the level?

A. That observation was used with all of the information which we had about it, in the reduction of the entire series of observations.

Q. I don't know whether we understood each other when

I asked you the possible error in locating the upper line of your gauging section?

A. Those were located from the shore.

Q. The vertical location of the water surface at your gauging station, I mean?

A. That was considered to be the same as the elevation at the end of the section. That is what you are getting at is it not?

Q. At both ends or one end?

A. A part of the time it was read at both ends; usually at one end.

Q. Did you ever observe any difference in the elevation at the two ends?

A. Oh, yes, slight variations; nothing that was at all surprising?

Q. How great a variation did you observe?

A. I don't recall.

Q. Would it have been more accurate if you had located your line from both ends rather than from one end?

A. It would have been a refinement that was hardly warranted.

Q. Can you give us any estimate of the difference in elevation which you did observe between the two ends?

A. No, I have no recollection of that.

Q. Could you within any reasonable limits? Could you say an inch, or half an inch, or a foot?

A. I should think at times it might have been as much as an inch.

Q. Suppose that the level of Lake Huron was lower, would the increment become greater or less per foot of drop as the level of the lake was lower?

A. It would be very slight, if any change; the tendency would be to decrease the increment.

Q. Suppose the level of Lake Huron should drop, say, five feet, would there be a substantial decrease in the increment?

A. I should not expect a very serious change from a five-foot drop.

Q. Suppose it should drop ten feet?

A. I don't care to go into that.

Q. Would you have any opinion on it at all?

A. No, sir.

Q. You say you have no opinion as to whether the increment would decrease substantially?

A. No, there has never been known to have been as low as a ten foot fall.

Q. Suppose that Lake St. Clair is at the same elevation during a series of observations, and different elevations in Lake Huron, would you say then that the difference of the discharge in St. Clair River was due to the changes in Lake Huron alone?

A. If that was the only factor named, I would expect that the effect would be due to that change.

Q. What other factor would you expect to enter into that situation?

A. What part of Lake Huron are you considering?

Q. At the north of the St. Clair River?

A. At the head of the St. Clair River?

Q. The part that you observed during the time you made your observations, and upon which these plates are based?

A. A given level at a given point on the St. Clair River would not necessarily mean that the level at another point was always the same at the time that the level at the first point became the same. It would depend upon what made the changes in level at the time. That is, I can conceive of temporary effects, such as wind, which would pile the water up at one part of the river, and make a different form of water surface than when the same level existed at one of those points under natural conditions without wind.

Q. Assuming just natural conditions, without wind?

A. Then I should expect that the change in discharge, the observed change in discharge, was due to the change in Lake Huron, that being the only factor there.

Q. Did I understand you to say, in answer to a question asked you by Mr. Wilkerson, that a decreased flow through the St. Clair River indicated a lowering of Lake Huron?

A. Other things being equal, yes.

Q. There might be a decreased flow, owing to an increase in the elevation of Lake Erie?

A. Yes, sir.

Q. And that would not indicate that Lake Huron was any lower?

A. Not necessarily.

Q. You testified in reference to the ice effects. What is the relative importance of the ice effect in the outlet of Lake Huron, as compared with the ice effect in the outlet to Lake Erie, the Niagara River?

A. I don't know what the relative importance is, for a

term of years. I think that the effect on Lake Michigan and Huron,—or the effect on the discharge of the St. Clair River,—might be greater at times—I will change that just a little—

Q. What we are trying to get at is, would the ice effect tend to raise the elevation of Lake Huron more than the ice effect would tend to raise the elevation of Lake Erie, or less?

A. For the same retardation of flow in the outlet, the effect on Lake Erie would be greater.

Q. I mean the conditions as they exist, and as they are customarily to be observed?

A. I am inclined to think that the effects on Lake Michigan and Huron are greater than they are on Lake Erie.

Q. Would a change in the channel of the Detroit River affect the level of Lake St. Clair?

A. Yes.

Q. An increased cross-section there, having greater flow, would tend to lower the level of Lake St. Clair?

A. Yes, sir.

Q. State whether or not, in your opinion, the levels of Lakes Huron and Michigan are controlled by the hydraulic conditions at any single section in the outlet of those lakes?

A. No, I think not.

Q. In your opinion would changes in the channel of the St. Clair River at points other than at the Rapids affect the discharges of Lakes Huron and Michigan, for a given stage?

A. Slightly.

Q. Would a change in the level of Lake St. Clair affect the discharge from Lake Huron?

A. Yes.

Q. Did you make any computations from the result of your observations as to the discharge through the St. Clair River, and the elevation of Lake Huron, with a view to determining the increment?

A. That was one of the main purposes of those discharge observations.

Q. Well, you made the computation?

A. Yes, sir.

Q. And the result of your computation was that the increment of Lake Huron, based upon those observations, was 19,238 cubic feet per second?

A. Approximately that.

Q. What percentage of accuracy, in your opinion, does that figure represent?

A. I think that that may vary, as I said in my direct testimony, from about 16,000 to 23,000 or 24,000,—24,000.

Q. There is a range there of about 50 per cent.?

A. Yes, sir.

Q. And have you any explanation to offer, other than the lack of precise and accurate methods of determination of the difference in results obtained by you as the result of your observations and the results shown by these plats, as to the increment from Lake Huron?

A. It is not a question of accuracy of methods of observation; there is no such error as that in the observations.

Q. Did you use a different method of computation from those employed in this chart?

A. The difference is due to the amount of the change in discharge which is charged to the level of Lake Erie, and the amount of the change in discharge charged to the level of Lake Huron and Michigan. That is where that large possible error of increment comes in.

Q. Do you think it possible that there might have been a change in the regimen of the St. Clair River, and that that might account for some of the difference?

A. It is possible but not probable.

Re-direct Examination by Mr. Wilkerson.

Q. Counsel in cross-examination asked you something about changing bench marks. I think you testified on that.

A. In connection with those tables?

Q. Yes.

A. Yes, sir.

Q. Did that change have any relation to or bearing upon the determination of the increment or the lowering—

Mr. Williams: We do not claim it does have.

Mr. Wilkerson: You do not claim it does have?

Mr. Williams: No.

Mr. Wilkerson: Q. Now, counsel put to you some questions that were predicated upon the assumption that in measuring the levels of the lake at a given time, the measurement would be taken under conditions where by reason of a storm or some other local condition, the level of the lake would be temporarily affected by that. Assuming that you did at any one time take some measurements when there was that temporary condition, I wish you would explain a little more fully just how that particular observation would be treated so far as

correcting it with reference to other observations, and taken in combination with others, taking into consideration the fluctuation that the lake made?

A. That is the reason or at least one of the main reasons why these points which we get in making observations do not fall on the straight line, showing the relation between the height of the lake and the amount of discharge.

Q. Now, looking at one of those lines that are drawn there, treating it as a question of eyesight, as well as of mathematics, what is the fact with reference to any error that might be injected, by reason of temporary conditions at one time being counterbalanced or overcome by temporary conditions the other way at another time? How does that work out in practice, when you come to group all these observations together?

A. In a line drawn as this one is on Exhibit No. 1, there are about as many points on one side of the line as there are on the other. That is what we mean by saying that the line fairly represents the observations and the variation of any given point from the line shows the error there may be in that observation. If every measurement were exactly correct, we would only need to take two to get this increment.

Q. So that even though there may be a large chance for error in one observation by reason of temporary conditions when we have simply the single observation in mind, what is the fact with reference to the comparative error when we speak of the general result which is reached from the combination of a large number of these observations, and of many series of them?

A. A great many of the errors of observation are what we call compensating; that is they may at one time make the result too large and at another time too small. There are certain other errors which are constant errors. The compensating errors tend to compensate each other; and the effects of wind and storms and things of that kind are of that nature. And if they are so serious as to warrant it, they sometimes cause the rejection of an observation; although that is rather seldom done.

Q. Isn't this principle that you have just pointed out here something that enters into—is it or is it not something that enters into the determination of any rule which is derived from a long series of observations? Take for instance tables of mortality, derived from actual observation.

Mr. Williams: I do not assume that the witness is an expert on mortality tables, too.

Mr. Wilkerson: Q. You know in a general way how those tables are derived, do you not?

A. I think that that might be put as an illustration of any engineering data that rests upon observation; no observation is absolute.

Q. Now, I have used here, for the purpose of comparison, mortality tables, which are things that are used as the basis of computation in all the affairs of life and are recognized in courts as stating the results with substantial accuracy. For one time, for instance, there will be temporary conditions that intervene, as for instance the prevalence of an epidemic at the particular place where the observation is made; while there may be another period, at another place when there is something that tends to compensate that. That is, is that a fair analogy to—

A. I should hardly think so. If our engineering data were not any better than that—

Q. I mean not with respect to the degree of accuracy, but with respect to the method?

A. Qualitatively, yes, but not quantitatively.

Q. Mr. Sabin, if the water surface on the cross section may not be quite level across and the two gauges show slightly different heights, does the same condition obtain when the soundings are made, so as to eliminate any error which may come in by the arching of the river?

A. What I understood the counsel to have in mind when he inquired about that was a temporary effect due to wind, which may pile the water up on one side of the section slightly; and if that is what you are referring to, of course the soundings might not have been made under that same condition. But if the wind piled the water up on one side of a section by an inch at one time, it would be as likely to pile it up on the other side at another time, and it would be one of our—go in as one of our errors of observation.

Q. In the case in which you assume, in response to the question of the counsel on cross-examination, that the one gauge was an inch higher than the other, what would be the error that would come from that, would it be a substantial one; error in the discharge?

A. Very small.

Q. Can you state that more definitely than that, what do you mean by very small?

A. Perhaps one-tenth of one per cent.

Q. In speaking of this increment of 19,000 cubic feet per second, that is the one deduced from your observations, what do you say, Mr. Sabin, as to the range of those observations, compared with the range of the observations on the charts which have been used in this case?

A. I have not in mind just how much the range was increased by the later observations, but it was increased, appreciably increased; so that taking the new observations with mine, a larger range of height was covered, and therefore the deductions from it would be, on that account, better.

Q. Then there was some difference you said that grew out of the manner in which Lake Erie was treated?

A. Yes.

Q. That is the allowance that has been made on account of that in these later computations would make the increment larger than the one as you had it?

A. It did make it larger.

Q. And I think you have already said that so far as the size of the increment as a maximum is concerned, the figures that appear on these charts are at the limit on that?

A. Yes, I think that that would be—for St. Clair I think that is the largest determination that I would expect to be the truth.

Q. In other words in dealing with those, whose interest it is to have the increment as large as possible, would you say that the substantial considerations have all been resolved in favor of the large increment?

A. I gave that as the upper limit of my determination.

Re-cross Examination by Mr. Williams.

Q. Mr. Wheeler in his testimony yesterday—you heard him testify?

A. I heard most of Mr. Wheelers' testimony.

Q. He testified that he had compared the observations that were platted here with the published observations, did he not?

A. I don't recall whether he said that he had compared the observations on these plates with the published observations or not.

Q. Assume that he did say that, what observations have been published other than those to which your attention has been called this afternoon?

A. The observations of 1902, in the report of 1902.
Q. His attention was called to that?
A. Yes, sir.

Further Re-direct Examination by Mr. Wilkerson.

Q. I do not recall, Mr. Sabin, whether you covered this ground or not, but to make sure I want to ask you a question with reference to the degree of the precision of these gauge readings in hundredths of a foot. What is your idea about that?

A. The gauge readings which were published in the 1903 report, and have been mentioned in this case, are monthly mean levels. Those are obtained by taking one or more observations per day on a given gauge. It is possible to have in one reading a considerable error; probably they are easily read within one-tenth of a foot; but occasionally mistakes may be made larger than this. I would expect that the result given for any month as the monthly mean would not have an error in it due to such errors of observation of the gauge of more than three-quarters of an inch.

Q. Have you anything to add in the way of a reason for that?

A. Principally from my experience in looking over gauge readings and reducing them, that it is so seldom that a mistake is made that I should think the final result, being a mean of a large number of observations, would be quite accurate.

Q. Then there is the check of the two gauges, is there not, on the same lake?

A. In many places there are two gauges.

Further Re-cross Examination by Mr. Williams.

Q. The testimony you have just given in response to counsel's questions, applies, does it, to the elevations recorded on pages 2867, 2868, 2869, 2870 and 2871 of Appendix FFF of the Annual Report of the Chief of Engineers of 1903?

A. It applies so far as that class of errors is concerned.

Q. And you would consider that the elevations recorded on those pages to which your attention was called correctly represent those elevations, subject to only the very slight errors which you have indicated might have crept in?

A. No, sir, I do not; I do not agree with that; I said so far as the errors of the kind which I mentioned were concerned.

Q. What other errors do you take into consideration in the compiling of these tables showing the elevations of these lakes?

A. Those tables give the difference in elevation between the lake surface and sea level.

Q. In addition to the error that you have pointed out as possible in the gauge readings, what would be the probable error or possible error relating to the elevation between sea level and zero on the gauge? You mean that there may be an error in addition to the error of the reading of the measurement between the sea level and the zero?

A. Yes, that is one error.

Q. To what extent would you say that error prevailed if at all, within what limits?

A. I don't know anything about the size of that, possible size of that error, but I will say this, which will answer your question, I think: that the difference between the error for one lake and the error for another lake is not very great.

Q. When you say not very great what do you mean?

A. Well, not greater than three-tenths.

Q. Of a foot?

A. Yes.

Q. And that is a constant, a continuous error?

A. For that given lake, yes, as published in those tables, yes. Then there is one other kind of error, or one or two other kinds of errors that may be in that table.

Q. Just enumerate them if you will; we want to get them?

A. The leveling from the bench mark to the water gauge may be an error depending upon the length, the distance; that will usually be less than one-half of a tenth.

Q. Are there any others?

A. No, I don't recall any others, so far as giving the elevation at the place where the gauge is located is concerned.

Further Re-direct Examination by Mr. Wilkerson.

Q. Just one question: with reference to this possible error in the elevation of zero on the gauge above the sea level, is that an error which would in any way affect substantially the result attained for increment of flow?

A. No, it would have practically no effect on that quantity.

Adjourned sine die.

Detroit, Michigan, May 24, 1909.

Ten o'clock a. m.

WILLIAM LIVINGSTON, a witness called on behalf of the government, was first duly sworn and testified as follows:

Direct Examination by Mr. Wilkerson.

Q. State your name please.
A. William Livingston.
Q. Where do you live?
A. Detroit.
Q. What is your present business or occupation?
A. I am at present with the Lake Carriers Association.
Q. What is the nature of your work in connection with that position?
A. I am supposed in a general way to look after the interests of the association. We have an executive committee that I work in conjunction with. I am supposed to look after, to a certain extent, everything that pertains to or affects the interests of navigation, in the way of improvements, etc., for instance deepening of harbors and rivers.
Q. How long have you had to do with matters relating to the navigation of the lakes?
A. Thirty-five years, certain.
Q. In a general way, what experience have you had in connection with such matters?
A. Well, as owner of vessels, handling of them, managing of them.
Q. Have you had any practical experience?
A. Well, a little.
Q. In connection with the management of vessels?
A. What do you mean by practical experience?
Q. Owning and handling them.
A. Some.
Q. I mean for you to cover in outline just what your experience has been, in matters relating to navigation on the lakes?
A. Well, my first vessel experience, so far as my memory goes now, dates back to 1867; I used to handle a good deal a small boat at that time; and I have been continuously connected with the lake transportation business. I think, on re-

flection, that makes 40 years instead of 35, and I have been continuously in the business all that time.

Q. What is it that determines the size of vessels which may be used in commerce on the lakes?

A. You mean at the present time?

Q. Yes. For instance, what determines how large a boat may be used in carrying on commerce between Buffalo and points up in Lake Superior?

A. There was a boat launched the other day that is 607 feet over all. I didn't measure it, but that is the statement made to me. That is the Chenango. I think the boat on that measurement would be a lot the largest boat on the lakes. She was launched either three or four weeks ago Saturday.

Q. What determines the depth to which boats engaged in lake commerce can be loaded?

A. The lowest point going through the rivers and, of course, the harbor or port she is consigned to. For instance, if a boat were loaded in Chicago or South Chicago, she would have to load to the depth of water there at the present time. She would be confined to two things: First, in rivers to the depth of water on Ballard's Reef, down here in the lower Detroit River, the reason for that being that the water crossing Ballard's Reef is a little shoaler than the Lime Kiln Crossing and at Bar Point. I should add, of course, if the harbor wherever she was consigned to and went to load, if that harbor was shoaler than Ballard's Reef, she would have to take that into consideration. But I do not know of any just now where she would have to take that into consideration. I think Ballard's Reef would be about the governing point.

Q. What about boats that are carrying to points on Lake Superior, Duluth, for example?

A. We take the depth of water there from the Poe lock. In other words, the engineer at the Poe lock, the assistant engineer, Mr. Sabin, keeps a constant gauge of the water there; and whatever depth he gives that we can load safely to going through the lock is what we use. It started in this season at 18.3; it is now 18.8. You can go through the Canadian lock with a little more water; I don't know just how much, because we do not have an official report on that, the same as we do on the Poe Lock; so that the Poe lock has to govern on that. Going there, it makes no difference if you load to a hundred feet outside, you have to take the shoalest spot and be governed by that. The water is lower this year in the Lake Superior district.

Q. Having in mind your experience with reference to matters connected with the navigation of the lakes, and speaking from that experience and from your knowledge, I wish you would state what would be the effect upon the load that a boat can carry of the lowering of the water at any one of these critical points in the channels of the lakes? For example, suppose that in some way the water in one of those channels was lowered an inch or two inches. What is the relation between that and the size of a load that a boat could carry going through the channel?

A. Speaking of the average?

Q. Well, take any boat that you have in mind. I would like to have you give us an explanation of that relation; state what the effect would be, based upon your experience.

A. Well, approximately speaking, taking the smaller class of boats, they are rapidly becoming obsolete.

Q. Go ahead and make you explanation in your own way.

A. As fast as they get into trouble or become disabled or anything of that kind, or lost, they are not replaced. Of course, now everything is steel. You take the last ten years, the last eight years particularly, has worked a sort of revolution here on the lakes. For instance, seven years ago—I am approximating; I can't give you to the month perhaps, but about seven years ago, for instance, the steamer A. B. Wolvin was built; and when she was built she was the largest vessel on the lakes. She exceeded in tonnage by 3,500 tons the next largest vessel. All the boats that have been built from that time on, with the exception of boats that were built for some specific traffic, say for instance the package freight traffic, something of that kind, have all been built of her type, all through; some a little smaller. But the smallest boat that is built now for business purposes, I know of none that will run under say 7,500 to 8,000 tons; and they run from that up. We have boats now that will carry 12,000 gross tons. I figure that the average per inch when a boat is loaded, say 18 feet or more, would be from 80 to 100 tons per inch. You take the lowest average, 80 tons, or cut it a little more if you choose to 75 tons, on the present rate of freight.

Q. Let me put a question to you there, Mr. Livingston: Having in mind this average boat with reference to which you have been testifying, and assuming that there was a permanent lowering of the water at one of these critical points of navigation of one inch, and basing your answer upon

freight rates as they exist now, what would be the loss to that boat?

A. Of one inch?

Q. Of one inch on the navigation of a season, we will say.

A. Assuming the average boat, and putting it on the basis of 80 tons—you could cut that to 75, but call it 80 tons just for illustration purposes, assuming as a fair average, in other words a very conservative average, the boat made twenty trips during a season, one inch would make a loss to each boat of over a thousand dollars in a season. Each inch would add just so much more to it. In other words, a boat going down and crossing Ballard's Reef drawing 18 feet or 19 feet, each inch you cut from that would be just that difference in the course of a season. The loss would vary as the freight rates vary.

Q. Now, you have knowledge on the subject of the number of boats that are engaged in commerce on the lakes in a general way, have you, Mr. Livingston?

A. Yes, sir.

Q. Have you given any consideration to the question of the total loss to commerce on the lakes, which would result from this lowering we will say, of one inch, basing that upon the number of boats that are engaged in lake commerce. Have you given any consideration to that subject?

A. Well, I could do this: We have, roughly speaking, in our association—of course you understand I confine my attention practically to our own association—we have about 600 boats.

Q. I wish you would give us anything that would be helpful in determining the loss to the commerce of the lakes occasioned by that lowering, based upon your experience and your knowledge; any facts that you think bear on that within your knowledge, I wish you would give it to us.

A. I would be glad to hand you in a computation; I would have to make it. It would not take me long to make it. I can also in that connection give you, as we are just getting one out now, a printed list of all the boats in the association, and the tonnage, both gross and net, the tonnage of each.

Q. You started out by giving us the effect of that lowering upon the carrying capacity of one boat?

A. Yes, sir.

Q. You have knowledge, of course, with reference to the total number of boats that are engaged in commerce on the

lakes. I want you in a general way to give us the facts with reference to the aggregate effect of this lowering upon commerce, so far as you have knowledge on the subject.

A. Well, do you mean all the vessels engaged in commerce on the lakes?

Q. Excluding, of course, those that are engaged exclusively in traffic on Lake Superior.

A. Yes, but what I am trying to get at, Mr. Wilkerson, is this: I have got a fairly thorough knowledge, I think, of everything pertaining to the boats that belong to the Lake Carriers Association. I am not quite so familiar, of course, naturally, with the boats outside of it. I could give you pretty accurate statements regarding, say, the six hundred boats that belong to the association. That would take the cream of the carrying capacity on the lakes.

Q. Answer the question on that basis.

A. It would give you a great big average. I want you to understand when I speak about registered tonnage, for instance, when you have a boat that will carry say in the neighborhood of 6,000 tons, a 600 footer, in the neighborhood of say 6,000 tons gross tonnage, custom house measurement, that boat will carry 12,000 tons of freight.

Q. Have you given the number of vessels that belong to the owners who are members of your association, approximately?

A. I will give it to you approximately.

Q. About 600 I think you said?

A. Yes.

Q. What percentage of that number of vessels is engaged in through traffic?

A. By through traffic you mean that pass the Detroit River, loading above?

Q. Yes. Practically all of them?

A. All of them, yes.

Q. Would all of the 600 be affected by the lowering of the lake levels to the extent of an inch?

A. No, sir.

Q. Which would not?

A. You take the boat for instance, as you can readily see, the boat that was so small that it didn't draw depth of water enough to be affected by the water, for instance, at the lowest point, of course an inch would not affect that boat.

Q. About what proportion would be affected by lowering?

A. I would prefer before stating it under oath to figure it out, but if I were to give it to you approximately, I would say 70 per cent.

Q. Seventy per cent. would be affected?

A. Yes.

Q. Would you say at least 70 per cent.?

A. I think so. I can figure it out. I can give you one fleet, if you care to have it, approximately.

Q. All right.

A. We have one fleet on the lakes that has 73 ships.

Q. What fleet is that?

A. Pittsburg Steamship Company.

Q. Give us the facts with reference to the Pittsburg Steamship Company.

A. Seventy-three ships have been loaded to 19 feet, but 18 of those 73 could load to 21. These boats in a normal season carry 10,000,000 tons, so that if you take these boats, they will make more trips than I gave you, more than 20, perhaps, in a season, but I did not think it was fair to take them, for the reason that they are peculiarly situated. In other words, they can make more trips per season than any other fleet on the lakes, owing to the advantages which they have in their loading and unloading facilities. No other fleet on the lakes has the advantages they have for loading and unloading, facilities for dispatch. But if you take that fleet alone for instance, if you cut them down to 20 trips, was that two inches you figured on?

Q. Figure it on the basis of an inch.

A. The loss for that fleet alone would be, roughly speaking, over $85,000 on one inch; that is on the present freights.

Q. I think you said that of the vessels that were connected with your association about 70 per cent. would be affected by this lowering?

A. Yes, sir. I don't give that as positive.

Q. Taking it on the basis of 70 per cent., what would be the total loss to the commerce of the vessels that are connected with your association? I wish tc get a general idea on that.

A. Roughly speaking, about $650,000.

Q. That is for one inch?

A. That is for one inch.

Q. What proportion of the vessels that are engaged in commerce on the lakes and that would be affected by this low-

ering, would you say are connected with your association? I put that with a view of getting some idea of the total effect. You know approximately, do you not, about what percentage of vessels that are engaged in commerce on the lakes, that is of the largest, the ones that would be affected, belong to your association?

A. The lumber fleet would be out entirely, because none of the lumber fleet draw enough water to be affected. But outside of that, if you take the boats in the ore and the grain trade and that class of boats, I should think seven-eighths of them would be a fair estimate.

Q. That is seven-eighths are in your association?

A. Yes, sir.

Q. You think you are within safe limits when you say more than 80 per cent.?

A. I think so, sir.

Q. More than 80 per cent. belong to the Association?

A. I really do not know of any—yes, I think that is a fair estimate.

Q. So that the total loss to the commerce of the lakes would be about one-eighth more?

A. Yes. I am speaking now of the depth of water. I mean to be understood this way: that seven-eighths of the loss would be borne by the members of our association, from the fact that more than seven-eighths of the boats that draw that draft of water are in the Lake Carriers Association.

Q. When you have given us this information with reference to the loss to the commerce on the lakes from that permanent lowering, in order to get the total loss, you would have to increase the figures you have given by the amount lost by the vessels outside of your association?

A. Yes; the figures I have given, $650,000, are what 70 per cent.—I am not sure but I have made a mistake, because I was figuring the whole, and I have made a mistake on that. I was figuring the whole, and there is a certain percentage that would not load to that depth. I took the whole 600 vessels and I made a mistake. There is a portion of our fleet would not be affected, because when they are loaded to their utmost capacity, on account of their size, they would not be affected.

Q. The correct answer would be 70 per cent. of this $650,000?

A. Yes.

Q. Which would be between four and five hundred thousand dollars?

A. Yes, I have added 30 per cent. that I should not add. I think that is a very low estimate, but I had to give it approximately.

Q. That would be between four and five hundred thousand dollars?

A. Yes, it would go half a million, easy.

Q. You think that is a low estimate?

A. I think that is a low estimate, yes, sir.

Q. Now, coming back for a moment, Mr. Livingston, to the question of limitation upon the size of the vessels which engage in commerce on the lakes; what would be the effect with reference to the size of those vessels, if it were not for the limitations that are imposed by the depth of water in these critical points of navigation?

A. Why, it would very largely increase their carrying capacity, of course. You know the question of the 25-foot channel has been brought up a number of times. In fact, a survey has been made in some places regarding it, but the cost was so very great—

Mr. Williams: Just a moment. I object to the answer to this question as not being responsive to the question.

The witness: Well, sir, if you put the question so I understand it, I will be glad to answer it.

Q. (The question was read to the witness.) The fact I am trying to bring out, Mr. Livingston, a little more definitely is this: it relates to the extent of the effect of this lowering of the lake levels upon the future commerce of the lakes, and that in relation to the size of the vessels which can engage in that commerce.

A. Naturally the size of the vessels has to be limited to its present capacity, or, that is not putting it fairly, because we are building vessels right along with reference to getting a greater depth of water; consequently, all the vessels that are built now are built with reference to that in the future. That is, that we will eventually get the 25-foot channel. I can put that another way: all our modern vessels could load considerably deeper if the water would admit of it; in other words, if the shallow spots would admit of it.

Q. That is the fact I wanted to bring out.

A. Just wait one moment; I think I have something in my hand here; I did not know just what you wanted. (Referring to memorandum.) There is one fleet of some 18

boats that can load to 21 or 21½ feet; quite a number of fleets, I have not got them all here. There are none of the modern boats but what could load to a greater depth than that, load now, provided they had the water to do it.

Q. Is there any relation, Mr. Livingston, between the draft of a boat and the length of a boat?

A. They are all built in proportion.

Q. I will put a leading question to you: is the length of the boat in any way limited to the draft of the boat, as a matter of practical construction?

A. Well, it is supposed to be, but you see here on the lakes we have been compelled—we could not get any deeper under the present condition of affairs, and so the result was they have gone to length. They are limited, of course, in breadth. No, I will qualify that, because the Poe lock has 100 foot gates. The Canadian lock, the Canadian Sault, that lock is 60 foot wide, so, of course, going through that lock they are limited to the width.

Q. The question is, when you impose a limitation upon the draft of a boat, do you or do you not as a result of that impose a limitation upon the length of a boat that may be constructed with that particular draft?

A. It is generally figured that every marine architect in figuring out the cost of the boat, that he makes her depth—just as they do with the vessels on the ocean—he makes her breadth and her depth of beam proportionate to her length. We will say 1 to 10 the scale may be; that varies. But here on the lakes, on account of the shallowness of the water, we have been compelled to go outside of this variation, as evidenced by the fact that we have got quite a lot of 600 footers on the lakes and if they had been built strictly according to the scale they would have had greater depth on account of their length. But the theory was they would put in compensation straight against that.

Q. These boats that are constructed that way out of proportion you say—

A. I do not say they are out of proportion.

Q. Out of the orthodox rule?

A. Out of the standard rule.

Q. Out of the standard rule, do they hog in the middle?

A. No; the way that they have—as a matter of fact, most of these large boats have been made up in this way, so as to comply with the standard rule; they have given them a greater depth of water in anticipation of getting three or four more

feet of water within a reasonable time, so that although they do not actually draw it, they have still got the depth of hold. It would be pretty difficult, a man would be a bold man to say just what limits we will reach here on the lakes, any more than they would on the ocean.

Cross-Examination by Mr. Williams.

Q. What is the depth of water at Ballard's Reef?

A. It is 20 feet today. I think the water has been coming up a little.

Q. What is the depth of water at the Poe lock?

A. The depth of water at the Poe lock is 18 feet 8 inches, the latest report I have.

Q. The real critical point, then, is the Poe lock, is it not?

A. Coming from Lake Superior.

Q. Outside of Ballard's Reef that is the real critical point?

A. Yes; the Lime Kiln Crossing has always been the "Hell Gate," you know.

Q. At the present time what is the depth of water at the Lime Kiln Crossing as compared with Ballard's Reef?

A. Well, it is the same thing, 20 feet. Ballard's Reef is the gauge for Lime Kiln Crossing; it is just at the entrance, you know, of Lime Kiln Crossing.

Q. In your experience, is it your observation that those who are building vessels for lake traffic are building with a draft to meet the present or the future probable depths at these critical points?

A. I think the majority of the boats that are built now are built with a view to future depths. There is a strong, definite feeling in the minds of many of our vessel men and owners that we will get 25 feet. The question of cost is what comes up, getting the appropriation from Congress.

Q. Suppose there were an unlimited depth of water, that is, I mean a depth sufficient so that it could not in any way interfere with the draft of vessels on the great lakes, and at these critical points, to what depth would you consider it practicable to construct a lake vessel, what depth of draft, assuming there was no limitation whatever, so far as the critical points are concerned?

A. You mean that to apply to harbors, too?

Q. Yes.

A. Because it would not make any difference if you had a hundred feet outside, if you only had 20 foot depth in harbors.

Q. Assuming harbors having sufficient depth to meet any requirement that you might have?

A. I could not place a limit on that. Perhaps I can answer you in another way. You remember when the Great Eastern was built on the ocean, she was 640 feet, and was considered a failure. The result is now we have big boats in commission on the ocean that are 800 feet in length, 789, the Lusitania and Mauretania. There are two boats under construction so I am told—I do not vouch for it, but I think the contract has been let, although I am not positive about that, to build two trans-Atlantic liners of 1,000 feet.

Q. What is that thousand feet?

A. Thousand feet over all.

Q. That is in length?

A. That is in length.

Q. But I am speaking of the depth of draft?

A. Well, they will have boats, the deepest channel they can come in, the Ambrose channel at New York, when that is completed is to be 40 feet in depth.

Q. What I was trying to get at was this: Assume you are not limited in the depth of water either at the critical points on the Great Lakes or in the harbors, and that you are to do business, what amount of draft would you consider it practical to have in lake carrying boats?

A. Oh, I could not limit that. If you have your unlimited water, could draw any amount of water you wanted, I could not limit that. I could not give you—would not want to pass an opinion on that, because you see here ten years ago if a man had—

Q. Never mind about ten years ago. Answer the question.

A. I beg your pardon, I want you to mind about that, because ten years ago—you are asking me questions and I want to be straight about it—ten years ago if I or any other man in the business had stood up and predicted boats of the size of the Wolvin and the present line of boats we are building would ever be built on these lakes, that man would have been considered a fit candidate for a medical asylum.

Q. Is that the reason you say you do not want to make any prediction now?

A. Yes, because commerce on the lakes has gone forward with leaps and bounds, and I would not attempt to predict what the future might be.

Q. Now, assuming that there was 25 feet of water at the critical points and in the harbors in which your proposed

lake carrying vessels are to do business, what would be according to your information and experience the normal length over all of a boat drawing say 22 feet?

A. It would depend a little on her beam. You take such boats, for instance, as the Chenango launched the other day—

Q. I am not asking you for illustrations. If you can answer the question I wish you would; if you can't answer I would be very glad to have you say you do not care to express an opinion?

A. Then I will say no, I cannot.

Q. Is it true, according to your information and experience that vessels are now constructed longer than they would be constructed if it were not for these shallow points, for the purpose of carrying the same load?

A. Yes.

Q. And that increased length is for the purpose of compensating for the decreased draft, is it?

A. Yes, sir, but it is made up in beam, you understand, in breadth, to some extent.

Q. But the object of that is compensation for the decreased draft?

A. Yes, sir.

Q. The tendency, during the past ten years or so since 1900, has been to increase the size and draft of lake vessels, has it not?

A. Yes, sir.

Q. Can you state approximately the increase in average carrying capacity of lake vessels since 1900?

A. Approximately, yes.

Q. About what increase would you say?

A. Well, let me think a moment. Did you say since 1890?

Q. 1900?

A. Oh, 1900. Since 1890, about the largest boat on the lakes was 3,000 tons, and when I speak of tonnage—

Q. You say 1890, you mean 1900?

A. I will get to that in a moment. When I talk about the carrying capacity that has nothing to do with the Custom House measurement. In 1890, about the largest boat on the lakes carried about 3,100 tons of ore. It gradually increased from that up to 1900, until we may have had a boat that reached a carrying capacity of 5,000 tons; I am not positive about that. But there has been an increase from 1900 up to the present time of the difference say between a boat that could carry 5,000 tons up to the present carrying capacity.

We have had some boats that I think have gone into South Chicago that carried over 12,000 tons.

Q. Would you be safe in saying that the average carrying capacity of the lake vessels has increased a hundred per cent. since 1900?

A. I should say so, yes, sir, all the new vessels built.

Q. And that refers to the new vessels built?

A. Yes, sir.

Q. You have stated in answer to Mr. Wilkerson's questions, but I do not understand it and perhaps you can explain it so that even I can understand, that the gross tonnage would be 6,000 tons, but the boat would have a carrying capacity of perhaps twelve thousand?

A. Yes. I have some data I could give to you on that.

Q. Just explain how that is. I do not care anything about the details of it.

A. It is the government system of measurement. That is all I can tell you. It has been used ever since I have had any experience. For instance, take boats like the Gary and the Corey and this larger class of boats, 600 footers, their tonnage will run 5,900 tons, that is Custom House.

Q. That is gross tonnage?

A. Yes.

Q. That is according to government measurement?

A. Yes.

Q. What you would actually carry is what you will weigh and collect freight on?

A. Yes. It goes all the way through. For instance, I happen unfortunately to own a boat; she has a Custom House measurement of 1,700 tons. She carries for the present draft of water about 3,150 tons of ore.

Q. Mr. Livingstone, what would you say as to the comparison, if any, that you may be willing to make between the facilities for lake commerce at present and the demand for shipping facilities on lake carrying boats? Is there a sufficient number of boats to take care of the traffic?

A. To-day there is.

Q. And if there were a greater demand for transportation facilities on the lakes, there would be an increased number of boats to take care of that demand very probably?

A. We generally build a little ahead, always.

Q. What would you say as to the present situation, that you would be able to take care of more commerce than is actually taken care of on the Great Lakes, with the present facilities?

A. If the business of the country was normal, we would have but little if any tonnage to spare. Last year, being the panic year, or 1907 rather, you know how badly that affected the iron and ore trade, and what a large percentage of tonnage that is on the lakes, and the fact that Congress is chewing away just now on the tariff bill—

Q. Take last year, for instance, you had an excess tonnage?

A. Oh, we had excess tonnage, last year was the panic year, 1908.

Q. Did you have any excess tonnage in 1907?

A. No, not in 1907. Every available ton in 1907, so far as my knowledge goes, was in use; the largest year in the history of the shipping business on the lakes occurred in that fiscal year. I could give you the exact figures from my report in the office, but I haven't it with me. It was the largest in the history of the United States.

Q. What is the expense connected with the operation of one of these large lake freighters for a season, approximately?

A. Well, you know managements differ a little; approximately say $160 a day.

Q. That would be for how many days?

A. We generally figure about, being in commission, generally figure 240 days; that is for an average. Some seasons are a little longer; some are a trifle shorter.

Q. Two hundred and forty days at $160 a day?

A. $160, I am giving it to you approximately. You know some men will run their boats a little more economically than the others; some will carry more cargo, more passengers than others, and these things vary. Some will live better than others.

Q. In your opinion then about $40,000 would cover the expense?

A. Roughly speaking.

Q. The figures you have given would approximate $38,400?

A. The insurance on one of these boats amounts to between $16,000 and $17,000 dollars a year.

Q. Do the figures you give include insurance?

A. Yes, sir, I figured that. You understand that was an approximate figure because you see the insurance foots up so on a modern vessel. To-day, the insurance runs between $16,000 and $17,000.

Q. In giving your estimate, approximate estimate, do you

include anything in that for interest charges, or is this just operating expense?

A. Those are operating expenses. Include what did you say?

Q. Interest charges or depreciation on the vessel?

A. No, sir.

Q. What is the cost of one of those large vessels approximately?

A. Ten thousand tons, they run about $400,000. In some cases they will be built for a little less; sometimes a little more. It depends on the state of the iron and steel market, but about $400,000. If you take a 600-footer, built right up to date, and she is fitted up with perhaps a private cabin and separate dining room, private dining room, some of them run up perhaps to $440,000, or say $400,000. They will carry 10,000 tons of ore on an average draft of water; some even with a little less, you know.

Q. What in your judgment is the average life of one of those vessels?

A. These steel vessels?

Q. Yes.

A. I can't tell you that, because you understand that steel ships are comparatively new on the lakes as compared with the ocean. Then comes up the question as to how far rust is going to affect it, whether fresh water is going to affect that. That is a matter I would not like to pass on.

Q. What is the longest that any one boat has been in service?

A. I should say fifty years.

Q. How long has the longest one you have known been in service?

A. That is the steamer Michigan. She has an iron hull. She has been in service nearly sixty years now. They cut a piece of iron out of her hull, that must have been nearly twenty years ago, she was then forty years old, and the government had their engineers cut a piece out of her hull to look at the iron, etc., and they pronounced the fibre in connection with the piece they cut out as sound as the day it was built.

Q. If you were going to make an estimate, do you think fifty years would be conservative?

A. Yes, sir, I would. At that, I am only guessing. I think this: a good deal would depend on the care a man took of his vessel, having it scraped and the rust taken off; keeping it

painted inside and all that. It is like a man taking care of his health.

Q. What would you consider a fair interest charge, if you were going to figure on a valuation of $400,000 on a boat, and if you were going to ascertain whether you were making a profit or not?

A. You mean depreciation per year?

Q. No, I say interest charge?

A. Oh, interest on the investment; that is the return a man ought to have?

Q. Yes, if you were to figure whether or not you had a profitable year, you would figure first interest on your investment of $400,000?

A. I would.

Q. Your depreciation, and your operating expenses and your receipts. What interest charge would you consider a fair charge?

A. Well, I would figure something this way: I would take first, of course, all the actual expenses of the boat, all the money paid out and I would add to that 5 per cent. for depreciation. And then I would figure the return I should have on the face of that, above all.

Q. Would you consider it necessary to figure 5 per cent. depreciation on a boat that was likely to last fifty years?

A. Well, yes I would.

Q. Or would you include in that 5 per cent. the maintenance of the boat, repairs, and keeping it in condition?

A. Well, perhaps partially, but if you will let me explain when I say partially, you understand I would expect the hull of the boat to outlast for instance several series of boilers. Boilers subject to pressure, etc., wear out and have to be taken out. I would not class that in; so that I would take that out of depreciation. You take the life of an engine; take our triple expansion or quadruple, whatever they might be, they would have to be probably replaced after a certain length of time. I would in that 5 per cent. include the up-keep of the boat, keeping the boat in good condition, and any minor expense I would include in the 5 per cent. Then there is another thing you have to figure on, the changes in boats. You build a boat to-day, you think she is modern and up to date, you think you have everything up to date, but five years later something else may come along, and you will find you are behind the light house; and that 5 per cent. is little enough depreciation.

Q. Would you consider 5 per cent. also a fair interest on the investment?

A. No, sir, I would not.

Q. I am not speaking of profits on your season's work. I am figuring on the value of the money invested in the boat?

A. I think that ought to be 6 per cent. for this business.

Q. About 6 per cent.?

A. Yes, sir, I think so.

Q. Do you know of any bond issues being floated on boats of that character?

A. Well, yes.

Q. At what rate of interest?

A. Six per cent. But I will say this, so that you will clearly understand me, that the usual way of issuing these bonds is on a 5 per cent. basis, and they are issued for ten years and 10 per cent. are retired each year, but some bonds particularly —and that perhaps is not a fair criterion. Last year, you know, was the panic year, a good many bonds, a large number of bonds in fact—I speak from absolute personal knowledge on this—were sold below par sufficient to make them 6 per cent.; in fact went down to 6¼.

Q. A 6 per cent. estimate on the investment would be liberal to cover even panic years, wouldn't it?

A. Why, you clearly understand that I do not think 6 per cent. investment for a man's profits in the business—

Q. No, I am not talking about profits.

A. Yes, I think 6 per cent.

Q. That is something you ought to get before you figure profits?

A. Yes, sir. Then I understand you this is 6 per cent.

Q. Is there anything else you would figure on in the way of charges against your investment in a boat of this character, besides what you have mentioned; 6 per cent. interest on the investment, 5 per cent. for depreciation and up-keep, $160 a day approximately for operating expenses?

A. Yes, and insurance.

Q. And insurance. Is there anything else that will be proper to be charged?

A. I don't think of anything else now. I might just add one thing: you understand your expense account is dependent on conditions; is liable to vary some for this reason: sometimes provisions advance and sometimes labor costs more.

Q. That is included in your estimate of $160?

A. No, I am talking about the present situation.

Q. The normal situation?
A. The present situation.
Q. And is it normal?
A. Yes, it is normal. You never can surely tell just what labor is going to do.
Q. It might be a little more or a little less?
A. Yes.
Q. It is as likely to be one as the other?
A. Our experience on the lakes is it has never been less; it has been a constant increase. The experience of the last twenty years shows it has been in increase; wages increased, materials increased, living has increased. Help demands a great deal more than it used to.
Q. Have you any data from which you could give us accurate information as to the amount of money expended in any one season for repairs and maintenance of one of these large boats?
A. I could get it for you; but that is outside of extraordinary expense. You understand if a boat had a collision or broke down or for instance if she broke her cylinder, something of that kind, that would be extra. You mean a boat that runs through with just the ordinary—
Q. The average expense?
A. Yes, I could give you that; I could get it for you. I can't give it to you right now.
Mr. Wilkerson: To get the average, you would have to take the extraordinary with the ordinary?
Mr. Williams: The average conditions.
The Witness: I understand you mean a boat that runs through the whole season with the ordinary risk she takes, with nothing unusual happening during the season.
Q. That is right.
A. Because these accidents vary so much.
Q. Those accidents are usually covered by insurance, aren't they?
A. Yes.
Q. So that that would not be a proper element of charge in this?
A. As a rule they are covered by insurance.
Q. You will bring us those figures I have just asked for, this afternoon?
A. Yes. I do not know whether I can give it this afternoon. I will agree to turn it in the next day or two.
Q. Just as soon as you conveniently can, and before we conclude the hearing?

A. I have got a few things to do just now. I may want to increase that expense account per day before I get through.

Q. Now you have given us an estimate of the value to the vessel owner of a carrying capacity of 80 tons?

A. Yes, sir.

Q. For a season. And you estimate that value to be about a thousand dollars?

A. Yes.

Q. Basing that on present freight rates?

A. Yes, sir, based on 65 cent rate, from the head of the lake. This reduction of rate was made from 75 cents to 65.

Q. Was that thousand dollars a season gross or net?

A. That thousand dollars is gross.

Q. Nothing taken out for the expense of loading and unloading?

A. Yes, sir. I made a low estimate, just jumping at that, but I made the basis, my hasty conclusions, I made it on the basis of 65 cents, and it costs 20 cents a ton to unload.

Q. Did you make that estimate on the basis of 65 cents?

A. That was a rough estimate. I am trying to explain it was based on the present rate on freight, 65 cents a ton from the head of the lake. Out of that freight rate is paid about 20 cents a ton for unloading.

Q. What I am trying to get at is, does the thousand dollars include anything else; is that gross, without taking into consideration any of the expenses?

A. That is gross. That would be the only expense that would attach to the boat, because there would be the same expense for fuel.

Q. That applies to your half million dollars that you mentioned as being the loss to the entire fleet?

A. What I mean to be understood is this: that the actual loss to the boat would be this, supposing the rate was 65 cents a ton, that the actual loss to the boat would be 45 cents a ton.

Q. Is there any other expense connected with the carrying of this extra 80 tons besides the cost of unloading it?

A. None that I know of. The crew would be the same, the actual coal you would burn would be the same. I do not know of any other expense I could figure.

Q. Would a large load take any more coal than a small load?

A. I think it would be almost imperceptible, that.

Q. Would it take any more coal, if the vessel was capable of being loaded two feet deeper?

A. Oh, yes, if that is what you are getting at; I did not misunderstand you a bit. You are talking about 80 tons. I do say this: you take the percentage of coal, take it your way, take the percentage of coal used for six inches; you take the percentage of coal used for a boat drawing 19½ feet, and a boat built exactly like it, of the same power and the same boilers; one drawing 19½ feet and the other drawing 20 feet, the boat that draws 20 feet would burn some more coal; there isn't any question about that at all, but the proportion would be small. I think it is fair to say that there should be a little allowance made for it.

Q. Would it make any difference in the speed with which the boat moves?

A. Yes, it would make a little difference in the speed; still, by the same terms that would be very small. I would not go much on that for this reason: that your displacement in the water would be greater, and you would burn extra coal to make up for that displacement in the water, so that you could not count it both ways, you know.

Q. What is the widest beam of any of the lake carriers with which you are familiar?

A. Sixty feet is the greatest beam that we have at the present time. I have heard of one or two being projected wider, but not built yet. They have only been built within the last three years.

Q. Taking the 600 boats that you mentioned as being owned by members of your Association, 70 per cent. of which, you say, would be affected by the lowering of the water at the critical points—

A. (Interrupting.) At Ballard's Reef.

Q. At Ballard's Reef, do all of the boats included in that 70 per cent. navigate through the Detroit River?

A. Do they go through the Detroit River?

Q. Yes, on all their trips?

A. Well, perhaps, not; the largest portion do, but there is some that would not for this reason: you take a boat, for instance, going from Lake Superior to South Chicago, she does not come down the river at all.

Q. And she would not be affected by any change in the level at Ballard's Reef?

A. She would not be affected, no.

Q. What percentage of the 70 per cent. would you say ply between South Chicago, or any port—

A. I can't answer that question without looking it up; I would not like to answer it. I will look it up.

Q. Have you data from which you could determine that question?

A. Well, I could, so far as our own boats are concerned, I think.

Q. I mean so far as your own boats are concerned?

A. Yes, I think I can.

Q. Will you be kind enough to do so before the hearing closes. I am not particular as to the time but let us know what percentage of the boats do not pass through the Detroit River?

A. It is small as compared to the whole number; but then there is a percentage and I have an impression, but it is only an impression—I do not give it as a fact—I have an impression that in making my estimate of 70 per cent., it would allow for any that might go in the Lake Michigan trade; but that is my impression, not positive about it.

Mr. Wilkerson: Those would be affected by the Poe lock. The boats that come down from Lake Superior to South Chicago would be affected by the level of the water in the Poe lock?

A. Oh, yes, of course.

Q. As I understood you a moment ago, now the water is lower there than it is at these other critical points that you testified to?

A. Yes, sir.

Q. Eighteen and eight-tenths at the Poe Lock?

A. Yes.

Q. And 20 at Ballard's Reef?

A. Yes; just a shade less than that. We call it 20 feet.

Mr. Williams: Mr. Livingston is going to give us some figures and my suggestion is that we stop here. I do not think of anything more I wish to cross-examine him about except on those points, but I would like to reserve the right to ask him some further questions when he brings in that information.

Mr. Wilkerson: Certainly. You may reserve your right to question him further.

Re-direct Examination by Mr. Wilkerson.

Q. Coming back to this question of freight rates and the elements that enter into the determination of those rates, is there anything that enters into that with the exception of these items of cost and interest, cost of operation and allow-

ance to be made for depreciation. I refer, for example, to the fact of railroad rates and competition of that kind. Is that an element that enters into determining what the rate is?

A. No, that would affect the tonnage; it does not affect the general—

Q. I mean, would it affect any trade at all?

A. I must confess I do not think I clearly understand that. So far as the bulk of the carrying trade on the lakes is concerned, the railroad rates practically cut no figure, because we carry freight on the lakes at the lowest rate of freight known in the world. You take railroad freight, for instance, roughly speaking about the lowest estimate that I know of that has been made anywhere, and that is when the Lake Shore was publishing rates, these rates, I think they were about—the lowest freight rate that I know of now on any railroad is about four-tenths of a cent per ton per mile, about that. I do not give it exactly. And you see we carry freight on the lakes now for about seven-tenths of a mill per ton; so that there is no place in the world where freight is carried so cheaply as it is on the Great Lakes. The package freight lines, they would carry in competition to some extent with the railroads; but as a rule the package freight lines are owned by the railroads, and so they take their mileage *pro rata* out of whatever the rate would be. I would have to qualify that to a little extent; it would affect a little the grain rates, but we always carry it so much cheaper that it does not affect us seriously. It would, of course, if the railroads would go in, as they have done sometimes in Chicago, when they wanted tonnage they would go in just before the opening of navigation; they used to make a practice of that but they have not gone into that so much lately; they would slaughter a rate and make a low rate for the sake of moving a lot of the grain before navigation. But Chicago has ceased to be the great grain port that it used to be.

Q. Directing your attention to the line of questions relating to the lengthening and widening of the vessels that are engaged in commerce on the lakes, is it a fact that a vessel might be made longer and wider and yet not be understood as affecting in any way what you have stated with reference to the loss to commerce, by reason of diminishing the depth of the water in the channels and harbors?

A. I do not know that I get that quite clearly.

Q. (The question was read to the witness.)

A. Every inch you lowered the water would be a loss to

commerce, of course, because you would reduce the tonnage you carry. For instance, everything that is done now is done with a view to the future. Here is the new lock at the Sault that the government is building now.

Q. That is to say, without regard to how long or how wide you may construct vessels—

A. Not at all.

Q. The loss by reason of being unable to make the draft more than so much is always there?

A. Well, that is evidenced by the fact we are going to get more water; that is beyond a doubt, because here is the new lock at the Sault that is to be 1,350 feet long, 85 feet wide and 24½ feet on the mitre sill, based on a depth of water of 601.5 at New York, ocean level.

Q. You spoke about accidents to vessels being covered by insurance, that is to say about the loss resulting from accidents being covered by insurance?

A. Yes, sir.

Q. I assume it is not the practice, is it, to have an insurance which covers the lost time?

A. Oh, no, no.

Q. That always remains?

A. No insurance covers lost time; there might be a case arise, which Golden explains better than I can, a vessel might do this: in case she had a collision and the other vessel was found to be at fault, she would be able to charge demurrage for the time she was out of commission.

Q. But that has nothing to do with insurance?

A. Oh, no, nothing covers delay of that kind, nothing at all.

Q. So that in addition to the loss to the vessel because of the accident, there is always the lost time?

A. If a boat goes aground and she loses a week getting off, that is gone; she loses that utterly, or if by any other accident she loses time, no matter what the accident may be.

Q. Coming back to the question of construction again, what do you say about the strength of a vessel which is 600 feet long, which draws 20 feet, as compared with one of the same length which draws 30 feet?

A. I do not see any difference in them; the boat that is built to draw 30 feet, she is built under specifications required to give her a rating of Lloyd's 100, as they call it. That is a standard classification that is used on the other side of the water, that we have adopted over here largely. And so, allow-

ing for the difference in depths, etc., the longer you build the vessel as a rule, the greater depth you make her hold.

Q. Precisely, and it is a fact recognized in connection with the construction of vessels, is it not, that the long, shallow vessel is not so strong as the one of greater depth?

A. No, sir, she is not.

Q. The vessel which has the greater draft is the stronger vessel?

A. That is assuming, that is true—

Q. It is stiffer, isn't it?

A. A stiffer vessel, oh, yes. You take the shoaler vessel, if they build her right, they should put in some compensation, but the deep draft boat has the advantage. That is the reason that many of our boats now could draw several feet more water than they do; on account of that it gives extra strength, depth of hold.

Q. Counsel on the other side asked you some questions with reference to the effect of increasing the cargo on the amount of coal that it would be necessary to consume. Suppose you increased the cargo 1 per cent., would you have to increase the amount of coal which you burned 1 per cent.?

A. Oh, no.

Q. That same thing would apply to what you said about speed?

A. That would be about at the proportion.

Q. Does the same thing apply to the effect, if any, on the speed of a vessel; if you increased the cargo 1 per cent., would it have that effect on the speed?

A. In other words, supposing you carried a given number of pounds pressure; let us take a unit. If you had a boat that was carrying we will say 200 pounds of steam and she was drawing 19½ feet and then you load her to 20 feet and carried the same steam, same revolutions, it would not make as good time; you would have to accelerate your turns and burn a little more coal to get it, but the proportion would be very small as compared with the increased cargo.

Mr. Wilkerson: I think that is all until after you bring in the data in response to the request of counsel for the defendant.

Recess to 1:30 p. m.

May 24, 1909, 1:30 p. m.

CHARLES KELLER, a witness called on behalf of the Government, was first duly cautioned and sworn and testified as follows:

Direct Examination by Mr. Wilkerson.

Q. What is your full name, please?
A. Charles Keller.
Q. Where do you live?
A. I live here in Detroit.
Q. What is your present occupation?
A. I am Major of the Corps of Engineers U. S. Army; and I at present have charge of the office of the United States Lake Survey; that of the Engineer of the Eleventh Light House district, and of the United States Engineer office at Grand Rapids.
Q. What have been your preparation and what has been your experience in work as an engineer?
A. I am a graduate of the Military Academy, and of the Engineering School of Application. Since 1893 I have been engaged in the work of river and harbor improvement. In more recent years, I have been in charge for two years of the harbors upon the east shore of Lake Michigan. I have had for four years charge of the office of the Engineer of the Eleventh Light House District. I have been in charge of the office of the United States Lake Survey for two years; and I was for two years in charge of the rivers and harbors upon Lake Huron.
Q. Have you had anything to do with hydraulic measurements on the Great Lakes, if so what?
A. Since May, 1907, I have been in charge of the office of the United States Lake Survey which, since that time, has made hydraulic measurements upon the Niagara, St. Clair and St. Lawrence Rivers.
Q. Having in mind your experience as an engineer, what have you to say as to the effect of diverting a given quantity of water, as for instance 4,000 cubic feet per second, from Lake Michigan at some point, for instance Chicago, the effect, I mean, as to the lowering of the level of the Lakes?
A. In my opinion it would unquestionably lower the levels of Lakes Michigan and Huron; and all the connecting rivers and lakes below there.

Q. Would that effect be general and uniform?

A. It would be uniform over the entire chain of lakes with the exception of Lake Superior, which would probably not be affected.

Q. That is to say if there is a certain definite lowering at any one point, that lowering would be general?

A. It would be general, although not precisely the same amount on all the other lakes and on the rivers.

Q. When you speak of the term, lowering the level of the lakes, are you speaking of that in an absolute sense? By that do you mean as a matter of fact the level of the lake would be lower, or do you mean it would be lower than it would have been if there had not been the diversion at Chicago?

A. It would be lower than it would have been had there been no diversion at Chicago. As a matter of fact, natural conditions might be such as to obscure the natural effect of any diversion at Chicago.

Q. Where are the outlets of Lakes Michigan and Huron, Major?

A. In the St. Clair River, whose head is at Port Huron, and it discharges into Lake St. Clair.

Q. If you take water out of the lake at Chicago, what is the effect of that upon the quantity of water which goes out through the St. Clair River?

A. You eventually diminish by precisely that amount the outflow of the St. Clair River.

Q. What do you mean by the term "net supply" as it is used in connection with the water in the lakes?

A. The net supply which is in effect the discharge of the outflow rivers, is the difference between the precipitation upon the Great Lakes and upon the drainage basin tributary to the Great Lakes, and evaporation and other losses, such as percolation. In other words net supply is precipitation minus evaporation and minus other losses.

Q. Having in mind the elements which go to determine the level of the lakes at any given time, what is the relation or connection between rainfall, evaporation, absorption and runoff, and the water which would be diverted at a given point, say Chicago?

A. There is no connection whatever between them.

Q. That is to say, would the diversion of the water at Chicago have any effect upon any one of these other elements?

A. Oh, yes, it would. I misunderstood you. It would af-

fect the runoff eventually. It would not affect rainfall, nor could it affect evaporation.

Q. The only thing it would affect would be the quality of water that went out through the St. Clair River?

A. Yes, the net supply as we have called it.

Q. By that you mean this: the quantity of water which is in the lakes and the resulting level is the product of a number of different elements. If you divert a certain quantity of water from the lakes at Chicago, is that an element which would affect the level of the lake, that is have an effect upon the level of the lake, independent of these other elements?

A. It certainly would.

Q. Would that always be present as a controlling factor?

A. It will always be present as one of the factors which control the ultimate level of the lakes.

Q. I am about to show you some charts which indicate the relation between the quantity of water which flows out through the St. Clair River and the level of Lakes Michigan and Huron; also charts which have to do with the outflow from other lakes and the level of the water in those lakes. As preliminary to that, I would like to have you explain in a general way, Major, how you would proceed to determine the relation which exists between the level of the lakes and the outflow from the lake, and how you would proceed to determine the effect upon the level of the lakes of diverting this water at Chicago. State first whether it is possible to determine what that effect would be, and if it is how you would go about determining it.

A. The effect is determined by the process of making what are termed discharge measurements. The object of the measurements of a discharge at any given time is to determine what the flow of the river, whose discharge is being measured is, at the time that the discharge is being taken. When the discharge is measured, close observation is also made of the level of the lake from which the river flows.

Q. If I may interrupt you, how do you make those measurements which determine the quantity of water that flows out through the river?

A. The general process in use by the Lake Survey, and in general use everything for the determination of the discharge of a large stream is that of measuring the flow by means of current meters at a section, cross-section of the river, at a point on the river that has been selected because

of its fitness for this purpose. A section is fit for discharge measurements when the conditions of flow are uniform, steady; when the cross-section itself is deep and fairly uniform in depth; when the flow approaches at a good velocity say in the neighborhood of 4 feet or more per second and leaves it with a fairly good velocity; and when the conditions above and below the section are such as to indicate that the flow itself is steady and appropriate.

Q. Just what is a current meter, how is it operated in practice?

A. A current meter is an instrument of precision, in our opinion, which consists roughly of a wheel or propeller which is set in motion by the movement of the water in which it is immersed. The revolution of this wheel is indicated at the surface of the water through an electric current, which is alternately made and broken by means of contacts upon the shaft of this propeller. It is indicated at the surface of the water upon a register which is part of the machine. This register is merely a counter and discloses the number of times the propeller of the meter revolves in a given length of time, given number of seconds, to be accurate. As the meter is intended to measure velocity, it becomes necessary to express in a definite formula the connection between speed or velocity of the water and the number of revolutions of the meter wheel. This is done by means of rating operations in which the meter itself, in place of remaining stationary in the water, as it does when a discharge measure is being made, is drawn through the water at known velocities. That is, known velocities are recorded and are varied sufficiently to obtain what is known as the rating equation of the meter. From this rating equation and the curve which results from the rating equation, it is therefore possible, having the number of revolutions which the meter makes in a given period of time, to derive directly the velocity of the water which has caused these revolutions. Having used the meter in this fashion, in accordance with a program which has been definitely fixed as being sufficient to obtain the information which is necessary with respect to all portions of the cross section, from the meter registrations and the record that is made of them, and from the record of the levels of the controlling lake, we are enabled to plot diagrams which show the relation between lake stage and lake discharge, river discharge, and from this, in general terms, we are enabled to derive a law which is probably the law of discharge of the river whose measure-

ments we have been taking. I can go into further detail if you want, but I do not think it is material.

Q. I wish only the statement of the general process leading up to the plotting of these measurements and these charts, and the drawing of the line expressing that relation. I direct your attention to a map or chart which has been already marked in this case "Complainant's Exhibit No. 1, 2/15/09." Have you seen that before?

A. Yes, I have seen it before.

Q. What have you done in connection with determining the formula that are expressed on that chart, with reference to determining the accuracy of the line which is drawn there, expressing this relation between the stage of the lake and the outflow through the St. Clair River?

A. From a personal investigation of the method in which the discharge measurements of 1899 and 1902 were conducted, and from a personal knowledge of the methods which were pursued in 1908, I know that the measurements as platted upon this diagram represent with the highest attainable degree of precision the actual outflow of Lake Huron, at the time when the discharge measurements were made. And I believe that the straight line which is drawn through the platted points represents as nearly as any line may represent, the law which governs the outflow of Lake Huron, or the flow of the St. Clair River.

Q. To go a litle more in detail into what is shown on this chairt, I direct your attention particularly to the formula at the bottom of the chart and to the scale which is out at the side of the chart?

A. Yes.

Q. I will ask you first to explain the formula and then to state the fact with reference to the correctness of what is indicated on the scale there at the side?

A. An examination of the drawing itself shows that for a change of one foot in the level of Lake Huron, the discharge or outflow changes by 23,820 cubic feet. This same law is expressed in algebraic or mathematical language in the legend in which is the equation: delta H=delta Q divided by 23,820. That states in mathematical language what I have just described in ordinary terms. This equation means that for any given change in discharge in the St. Clair River expressed in cubic feet, the change in height of Lake Huron expressed in feet will be that change in discharge divided by 23,820.

Q. What name do you give to that figure, 23,820?

A. We have called it the increment, increment of discharge.

Q. Increment of discharge means what, to state it in simple language?

A. It is the change in discharge for one foot change of a stage in the controlling lake.

Q. How is that increment obtained?

A. By direct measurement from the line which is drawn on the diagram, by measuring the horizontal distance on the scale, which corresponds to a vertical distance of one foot, we get what is called the increment of discharge; and this has actually been done on the diagram which appears here.

Q. Now carrying out the conclusion from the line as there drawn and from the formula as you have explained it and from this increment of discharge as you have explained it, what is the fact shown with reference to the lowering of the level of Lakes Michigan and Huron for the diversion of 5, 10, 15, 20 thousand cubic feet?

A. The scale at the side which appears to be correctly drawn shows that for a reduction in outflow of 5,000 cubic feet per second there will be a reduction or lowering of level in Lake Huron of a trifle over 2¼ inches.

Q. And the effect of the diversion of 4,000 cubic feet at Chicago would be what?

A. Practically two inches, as shown by the scale.

Q. And for 10,000 cubic feet?

A. For 10,000 it would be a shade over 5 inches; for 15,000, it would be a trifle more than 7½ inches, and for 20,000 it would be slightly more than 10 inches.

Q. Now keeping in mind your experience in connection with these measurements and observations, what have you to say with reference to the accuracy of the conclusions based upon the platting of these observations, and upon the formula which you have just explained?

A. I think that in all probability the results that I have just given are accurate within approximately 5 per cent.

Q. Can you, without going through any long mathematical process, state why you put that at 5 per cent? What is the reasoning in your mind that leads you to say 5 per cent?

A. Well, as a general rule, we have found out in our discharge measurements that the line which most nearly expresses the law of discharge will be so drawn upon a diagram that the extreme measurements, those which diverge furthest from the line, will contain an error not to exceed

about 2 per cent. That in itself is probably an error that does not altogether measure the total error which appears in the measurement. It shows the internal or relative consistency of the measurements, but it does not exhibit the fact that it is possible that in addition to small errors due to the use of the meter itself, there may appear small errors due to the impossibility of measuring the cross section with absolute accuracy. And the final result will also show a very small error due to the slight errors of gauge readings, that may appear in the result. And while I have said 5 per cent., it is merely my opinion that the final result may show an error as large as 5 per cent. I do not believe it will show anything larger. I think all causes combined would probably aggregate at the very utmost 5 per cent.

Q. You have, in your study and investigation of this subject, had occasion to read what engineers, men in your profession, have had to say about the relation between the level of a lake and the quantity of water which flows out from it?

A. Yes.

Q. What is the fact as to its being generally accepted as something that is practically axiomatic, if you can use that term, that there is some relation between the level of the lake and the quantity of water which flows out through the river?

Mr. Williams: Let the record show that I object to the question first on the ground that it is leading; in the second place that it is calling for the opinions of others than the witness himself?

A. I have never known of any engineer who has disputed the general axiomatic proposition that the discharge of the outflow rivers varies directly with the height of the lakes themselves; increasing as the lakes rise and diminishing as the lakes fall.

Q. The only question then remaining for determination is as to the——

A. The quantity of change of discharge with a given amount of change in level.

Q. I understand you to say you have never known an engineer to question the general fact that such a relation does exist?

A. I never have.

Mr. Williams: I wish to note an objection to that question as a statement of counsel and not a question.

Mr. Wilkerson: Q. And further, that there may be no question about it: how generally have you given considera-

tion to what has been said on this subject; have you covered a good deal of ground?

A. I answer your question as generally as you ask it; I think I have read everything that has been written on the subject of the levels of the lakes as connected with the discharge of the connecting rivers. So far as I know there is nothing that has ever been written that I have not read, with greater or less care.

Q. Have you read everything you have heard of on the subject?

A. Yes, I have read everything that I have heard of.

Q. And what you have just said, the statement you have just made, is based upon that study?

A. It is a summary of that study.

Q. Now, what is the effect of the lowering of the waters of lakes Michigan and Huron upon the water in the St. Marys River, at the foot of the locks?

A. There is a lowering at the foot of the locks, but it is less in amount than the lowering of the lakes themselves.

Q. As a result of your study and investigation, are you prepared to make a statement with reference to the percentage of lowering there would be in the St. Marys River at the foot of the locks?

A. No, I am not prepared to make a precise statement.

Q. Suppose that Lakes Huron and Michigan were lowered a certain definite amount, and Lake Erie a certain known amount, what would be the lowering in the Detroit River and Lake St. Clair and the St. Clair River?

A. The lowering of the St. Clair River, of Lake St. Clair and of the Detroit River at various points would depend directly upon the amount of lowering on Lakes Huron and Erie. Lake St. Clair, or the level of Lake St. Clair, is directly connected with the level of Lake Erie by means of an equation, which if you desire I am prepared to give, as derived from the investigation of the Lake Survey.

Q. I would like to have you give that.

A. The height of Lake St. Clair at the Flats is h—.602 H+.373h′ times plus h′ times .373. Small h will give the change in elevation of Lake St. Clair due to change of H in Lake Huron and h′ in Lake Erie. If there is a change of a foot in each lake, the change in Lake St. Clair would be .975 in feet. The change in the St. Clair River between the head of the river and Lake St. Clair would vary from the full amount of the change on Lake Huron down gradually to a

limit which is set by the amount of change of the St. Clair Flats gauge. In the formula or equation above, h equals St. Clair Flats gauge, minus 575.12; H equals Harbor Beach gauge, minus 580.70; h′ equals Cleveland gauge, minus 571.96.

Q. That is to say at any one of the critical places of that change, the Detroit River or Lake St. Clair, the lowering would be some place between the total lowering of Lake Huron and the minimum?

A. And the corresponding change on the other lake.

Q. Which you have given?

A. Yes.

Q. How exact, in your opinion, is that statement that you have just made?

A. For any given change in Lake Huron and Lake Erie it is probably at least 10 per cent. wide of the truth; but for a long period of years it will come pretty close to expressing the average elevation of the St. Clair Flats gauge.

Q. I direct your attention now to a chart which has been marked "Complainant's Exhibit No. 2" under date of February 15, 1909, the same purporting to show the loss of level in the St. Lawrence River at Ogdensburg, corresponding to loss of outflow by reason of the diversion at Chicago. I will ask you to state whether or not you have examined that before; if so what examination you have made of it?

A. I am familiar in a general way with the processes by which this diagram has been derived, and I know it to be based upon actual discharge measurements made in the St. Lawrence River. And I further believe from examination that the line which represents the law of discharge of the St. Lawrence River is the probable law as based upon discharge measurements actually made.

Q. If water is diverted from Lake Michigan at Chicago, what effect does that have upon the outflow of the Niagara and St. Lawrence Rivers?

A. Reduces by precisely the same amount eventually the outflow of the Niagara and St. Lawrence Rivers.

Q. Why do you say that?

A. Because the outflow of these two rivers consists only of the surplus waters of the lakes. If anything is taken away from those surplus waters of the lakes up above, it is necessarily taken away from the outflow of these rivers.

Q. The formula and the increment is derived from the same process as the one that you have already explained?

A. As in the case of the St. Clair River, except that the

increment in the case of the St. Lawrence River is 28,870 cubic feet per second for a change of one foot in the elevation of Lake Ontario.

Q. And what result does that give as to the effect of the diversion of say 4,000 cubic feet at Chicago from Lake Michigan?

A. The resulting changes are somewhat smaller than they are on Lake Michigan and Lake Huron. For 4,000 feet, the lowering of Lake Ontario and the upper St. Lawrence River is about 1.6 inches.

Q. I show you two other charts which have been marked Exhibits 3 and 4 respectively of the same date as that given in connection with the charts already in evidence. No. 3 relates to the loss of level in Lake Erie corresponding to the loss of outflow in the Niagara River, and No. 4 relates to Lake Erie also; one being the International Bridge section and the other the Open Section. Will you take those two charts and state what investigation you have made of the matters to which they relate, and explain to us the result as shown by the charts?

A. I am familiar with the diagram concerning the discharge measurements at the International Bridge section, and I know personally concerning the discharges which were measured in 1907 and 1908, as these were taken during the time of my being in charge of this office.

Q. That is to say those measurements were measurements made under your direction?

A. Made under my direction in 1907 and 1908.

Q. And with your knowledge?

A. And with my knowledge.

Q. Go ahead?

A. The line which appears upon the diagram is in my opinion correctly drawn from the platted discharges, and represents the probable law of discharge of the Niagara River at the International Bridge Section. The diagram shows an increment of 21,900 cubic feet per second for a change of stage of one foot in Lake Erie. The second diagram relating to the Open Section of the Niagara River is based upon discharges which were measured before I assumed charge of the Lake Survey office; but I am familiar with the manner in which the discharge was measured, and I believe that the discharges themselves are correctly platted, and the line which represents the law of discharge correctly drawn: For the Open Section, the diagram shows an increemnt of 21,640 cubic

feet per second for a change of stage of one foot in Lake Erie.

Q. In order to get it in the record, what do those charts show as to the effect of a diversion of 4,000 cubic feet per second at Chicago?

A. They show about the same thing, a lowering of about 2.2 inches, corresponding to a diversion of 4,000 cubic feet at Chicago.

Q. In connection with Lake Erie there are two sections taken, one is the Open Section and the other is the International Bridge section?

A. Yes.

Q. Why were those two sections taken, Major?

A. The measurements at the Open Section were taken in order to verify the measurements previously taken at the International Bridge Section; and as a result they show a very close agreement between the two sets of discharge measurements.

Q. Now coming back to the question which I put to you with reference to the observations of the St. Clair River, as to the accuracy of the result which is based upon those observations, what have you to say as to the accuracy of this result with reference to Lake Erie?

A. I believe that the measurements at the International Bridge Section are considerably more accurate than those of the St. Clair River because of the fact that the cross-section itself gave opportunity for measurements superior to the opportunities which existed in the St. Clair River. The bridge offered an absolutely fixed platform from which measurements could be made, and absolutely fixed the points at which velocity was measured by discharge meters. At the same time, the cross-section itself was an absolutely fixed one. The nature of the bottom material was permanent, so that there could be no great uncertainty as to the area of cross-sections and absolutely no uncertainty as to the points where soundings were made.

Q. With reference to the substantial agreement between the result as shown from the observations at the Open Section and the one at the International Bridge Section, is there anything in that which to the engineer furnishes a basis for reaching a conclusion as to the accuracy of the statement you have made with reference to the general result?

A. It is very strong corroborative evidence of the results obtained at the International Bridge Section. The close agree-

ment must be due to very painstaking and trustworthy methods of measurement. The agreement in the very nature of things cannot be accidental.

Q. In your own mind, and in connection with your own opinion on this subject, has the fact that there is that agreement with reference to these Lake Erie measurements had anything to do with the statement which you have made as to the accuracy of the result showing the relation between the stage of the lake and the outflow through the rivers?

A. Yes, that is one of the principal grounds for my statement.

Q. The measurements on one of these sections was made from the bridge?

A. Yes.

Q. The measurements on the Open Section were made where?

A. Made about 1,800 feet below the bridge.

Q. And without the assistance which would come from making the observations from the bridge?

A. Yes.

Q. Referring again to that substantial agreement between the observations, does that indicate anything with reference to the accuracy of the observations which were made at the Open Section?

A. They indicate that the observations at the Open Section were themselves very accurate.

Mr. Williams: We will agree if the observations on the Bridge Section showed that the observations on the Open Section were accurate, the observation on the Open Section shows that the others were accurate too.

Mr. Wilkerson: Q. In the very nature of things, from which set of observations would you expect the highest degree of accuracy?

A. From those at the Bridge.

Q. Why?

A. For the reason I have already given, that the bridge itself was a more favorable cross-section for measurement than an ordinary open section can be.

Q. Coming back again to the thought just suggested by the counsel on the other side, having the observations on the bridge, with this element of greater accuracy present for the reason which you have stated, does the agreement that results from those observations and the ones at the Open Section furnish a foundation for making a statement and

forming an opinion with reference to the accuracy of the observations at the Open Section?

Mr. Williams: I object to the question on the ground it is leading; on the ground it is furnishing the witness with additional reasons for the testimony he has given already; and on the further ground that he has already answered the question several times.

A. I understand you to ask whether the agreement between the results at the International Bridge and those at the Open Section gives additional reason for believing in the high degree of accuracy in the methods used at the Open Section?

Mr. Wilkerson: Yes.

A. Yes, it does. It is the only independent evidence we have.

Q. On this same general subject of the correctness of results which are reached through the method which you have described, are you familiar with the measurements on the Niagara River, which were made by the Deep Waterways Commission in 1897 and '8?

A. Yes, I am.

Q. Those were the measurements made by the United States Board of Engineers on deep waterways. You are also familiar with the recent measurements which have been made on the river?

A. Yes.

Q. How do the recent measurements agree with the measurements of United States engineers on deep waterways?

A. For any given stage of discharge as published in the report of the United States Board on deep waterways, the figures are from ten to twelve thousand cubic feet per second in excess of the figures which we now give as being correct. And the reason for that discrepancy appears to have been that while the measurement of velocity made by the Deep Waterways Board was as accurate as anything that we do nowadays; that the soundings taken in ascertaining the area of cross-section were by no means as accurate as the later soundings, those of 1898 and 1899 being made with far higher degree of precision.

Q. Are you familiar with the measuremnets that were made by one Quintus in 1891 and '2?

A. I have read his published reports.

Q. Who was he?

A. He was assistant engineer; he is an assistant engineer in the employ of the United States Engineer Office at Buffalo.

Q. With reference to his measurements on the Niagara River, how do they agree with the more recent measurements?

Q. The agreement is only fairly good so far as concerns discharges pertaining to definite stages, but both his discharge measurements and those of the Deep Waterways Board show a substantial agreement with the Lake Survey discharges. In the derivation of the increment of discharge, the increment of discharge corresponding to a change of one foot in the level of the lake, they all give an increment between 20,000 and 30,000 cubic feet per second for a change of one foot in the level of Lake Erie.

Q. The larger the increment, the smaller would be the lowering for any given diversion, is that right?

A. Yes.

Q. What is the largest increment that has ever been derived from any set of observations that you know of?

A. I think the one of Quintus. That shows an increment of about 35,000, but I think that is an isolated case, and I think the largest increment that has any standing is the increment for the St. Lawrence River which is 28,800, or thereabouts.

Q. That is as high as anybody has ever called it?

A. As high as anybody has ever called it that I know of.

Q. And on these different observations, how low does it go?

A. Well some of the St. Clair increments go as low as sixteen or seventeen thousand cubic feet to the second; that is the lowest any of them have gone.

Q. That is the lowest increment that has ever been derived from any series of observations?

A. From a series of observations, yes.

Q. Going back to the Quintus observations, Major, can you make, after referring to the report, a more definite statement as to his increment?

A. I have here in my hand a copy of Mr. Quintus' results sworn to by him, in which he states the discharge increment per foot at or near mean lake level at 21,000 cubic feet per second.

Q. Now those are measurements on the Niagara River?

A. Yes, sir, made in 1891. And while that statement is

an answer to your question, in explanation of my previous answer I desire to call attention to page 4371.

Q. Make your explanation as clear as you desire.

A. I said in my previous answer his increment varied between 21,000 and 35,000 cubic feet per second. The flow which I have just read you from his report is for mean lake level. For a different stage of the lake, in the printed and published report upon page 4371 of Part 6 of the Annual Report of the Chief of Engineers U. S. Army for 1893 there is a table which shows in the last column a single increment of 35,000 cubic feet. That explains my previous answer.

Mr. Williams: Q. What was the lake level there?

A. He gives the lake level as probably between four and five feet; that would be four or five feet above mean lake level; and I imagine that is a deduction from his curve rather than an actual measurement.

Mr. Wilkerson: Q. So that we will not have to come back to it again, that 35,000 increment I understood you to say it is obvious from the report that it was not based upon actual observations but was a computation based upon the formula for a higher stage?

A. Yes, that is what I believe to be the fact; and I think the curve shows it.

Q. Just find what he says on that subject and read it.

A. I think the answer to your question is given from the table here, the table on page 4367 of the same report, which shows all the discharges which were actually measured, contains no discharge which was measured at a stage corresponding to that for which the increment was previously stated as 35,000 cubic feet per second.

Q. In the light of investigations which have been made subsequent to that time, was there any warrant in attempting to extend a computation with reference to the increment on the formula, to those higher stages which were not covered by actual observations?

A. That is what he has done in this table where he gives this theoretical increment of 35,000 cubic feet. The increment of 21,000 cubic feet is actually derived from the measurements themselves.

Q. Should he have done that?

A. It is not good practice.

Q. In the light of practical experience?

A. It is not good practice, and it is not ordinarily done.

Q. You are familiar with the conditions on the St. Clair River, are you, Major?

A. Yes, sir.

Q. What is the season of navigation on the St. Clair River?

A. I will answer your question as Engineer of the Eleventh Lighthouse District. As Engineer of the Eleventh Lighthouse District, it is my duty as early as possible to send from Detroit completely loaded and equipped the lighthouse tender belonging to that office. During the last four years, the date of despatch of the tender (and that represents practically the opening of the season of navigation) has been as follows: 1906, April 17; 1907, April 16; 1908, April 24; 1909, April 24. During three of those four years, the closing of the season of navigation was coincident with the final date of the last trip of the same vessel, and in those three cases, to the best of my recollection,—I have not verified the exact dates—the season of navigation may be said to have closed in the St. Clair River on or about December 15.

Q. During the winter months there is ice in the St. Clair River?

A. Yes, sir.

Q. What is the effect of that ice in the river upon the outflow of the water from Lake Huron?

A. The effect is to diminish or retard the outflow.

Q. As to this ice retardation, approximately when does it begin and when does it end?

A. In general terms it may be said to begin about the middle of December, and to end about the middle of April, although there have been exceptional years when it has begun earlier and lasted later.

Q. How about May?

A. The year 1901 is a typical year in which there was ice effects shown after the first of May, but as a general rule May is not an ice month.

Q. I wish you would take up this subject of the presence of ice in the St. Clair River and in the Niagara and St. Lawrence Rivers also, and state what information if any you have upon the subject of the effect of this ice retardation.

A. The only information that I have on the subject is derived from my reading of reports of investigations made by the United States Lake Survey into ice effects. The first investigations of that sort were the investigations into the ice effect in the St. Clair River. These investigations

were made late in 1900 and early in 1901, and they showed that the discharge of the St. Clair River measured at a time when the river was in its lower portion sealed by ice was considerably less than the discharge which corresponded to the existing level of Lake Huron. The discharge curve or formula derived from—

Q. I wish you would take up that subject, as the result of your experience and your study, and state just what your conclusion is with reference to that ice retardation; and what is the determination of the government?

A. My conclusion, independently of that of this office, my personal conclusion is that the ice effect is a large but unknown factor in the determination of the levels of the Great Lakes; and that up to the present time the Lake Survey has not made sufficient measurements to enable any one to form a justifiable conclusion as to the measure of the ice effect, either in the St. Clair River, or in any of the other rivers; the Niagara or the St. Lawrence.

Q. Are you familiar with the formulae which have been derived, bearing upon the subject of ice effect?

A. No, I am not familiar with any formulae that have been derived bearing directly upon ice effect.

Q. You have spoken in connection with the determination of the effect of diminishing the outflow through the St. Clair River upon the level of the lake, of the increment; what could you say on the subject of the relation between this ice retardation during the winter months and this increment, with reference to which you have testified?

A. The effect is to diminish the increment.

Q. Why do you say that?

A. Because the increment is the result of the increased head due to a rise in the level of the lake surface. The effect of that head is lessened by the increased friction due to the presence of the ice, or to put it in other words, the efficiency of the cross section when sealed by ice is less than it is when open.

Q. Taking the diversion of the water from the lake, at Chicago, as one element, and the presence of this ice in the St. Clair River as another element, when it comes to the determination of the effect of the diversion of the water at Chicago, is there anything in the presence of this ice in the river during the winter months, which in any way overcomes or counteracts the ultimate effect of that diversion?

A. No. It aggragates the effect of the diversion by in-

creasing the relation which the amount of the diversion bears to the value of the average increment; the increment during the ice months being less, the average increment for the entire year is less than if the river were open for twelve months; and as a consequence the effect upon the lake level is larger than it would be in the absence of ice effect.

Q. That is to say, if I may put the question in this leading way: it has the same effect as if the St. Clair River were smaller?

A. Smaller or narrower or shallower.

Q. Referring to the St. Clair River again, what information have you on the subject of the scouring of the river, as to whether it is changing its regimen or not?

A. During November and December, 1908, I directed that four cross sections in the St. Clair River, which had been permanently monumented or marked at a previous time so that they could be again identified for purposes of measurement, should be remeasured, with a view of finding out what change had taken place in these cross sections, since the previous measurements. The remeasurement was done, as directed by me, and I have here a table, of which Mr. Shenehon will exhibit the original, which shows that at the cross sections which are described in the Annual Report of the Chief of Engineers for 1900 as cross sections Culvert, Fish, Arthur and Stauber, there has been practically no change since the measurements of 1899. That is in a period of over nine years, there has been no measureable change in these cross sections. In cross section Culvert, the measurement showed a scour of about 1.3 feet on the section since 1901. In cross section Fish, there was an apparent shoaling indicated since the previous measurements. In cross section Arthur, a fill of about 2½ feet is indicated since the previous measurement, and in cross section Stauber no change is shown in the area of cross section. These cross sections were in the gorge of the river at its narrowest place, and where scour would be most likely to take place. They are also in what we regard as a critical or controlling portion of the St. Clair River.

Q. Based upon these recent observations then, which have been made under your direction, what is your conclusion as to whether there is any change in the regimen of the St. Clair River?

A. There is no evidence whatever to show any change in the regimen of the St. Clair River. At the same time that these cross section measurements were taken, we made dis-

charge measurements at a new cross section, and we made discharge measurements at a cross section formerly occupied for this purpose; and these discharge measurements were in absolute accord with the measurements that had previously been taken. There exists no evidence upon which to base any assertion of a change in the regimen of the St. Clair River at its head.

Q. About that time, were there any observations made for the purpose of determining the relation between lake level and discharge; that is were these observations used as the basis of any new computation on that subject?

A. The discharge measurements closely accord so far as they go. They were few in number, only thirty-seven in all, but they accord with the previous discharge measurements and are platted in the line of discharge that is exhibited on one of these plates, for the St. Clair River, to show that the law which was formerly deduced for the St. Clair River applies also at these sections.

Q. Is there anything in that that throws light upon the subject of the correctness of the statement that you have made with reference to the increment?

A. It shows that the increment as derived from previous measurements is probably correct and that the law of discharge has been correctly determined.

Q. Since you have been in charge of this work here, have you caused a new section to be measured, for the purpose of corroboration?

A. I have already mentioned that. We established a new cross section at the head of the St. Clair River, above the cross section previously used for discharge measurements. We called it cross section gorge. We had this carefully sounded, and thereafter we took discharge measurements at this new section and these discharge measurements showed discharges which accorded with the discharges deduced from the law here; that is for a given stage of Lake Huron as shown on the gauge, the discharge as derived from Cross Section Gorge corresponds to the discharge which would be taken from the line indicated on the plate.

Q. That is to say, I understand that the practical result of these later observations is in accordance with the law of discharge as it had been already derived from the previous observations?

A. Yes.

Q. What light if any does that throw on the accuracy of the formula which you have given here?

A. Which formula?

Q. On the chart?

Mr. Williams: I object to that. The witness, I assume, in answering the previous questions with reference to the degree of accuracy obtained in making these discharge measurements, took into consideration all the facts that he knew of, and he is testifying to some of those facts now. I object to counsel asking whether each specific item of information confirms the opinion which he has expressed as being the result of all his information.

Mr. Wilkerson: I think it entirely proper for the witness to state any fact or any element which he acted upon in making his statement with reference to the accuracy of the observations.

Mr. Williams: It would be entirely proper for the witness to do that, and for counsel to ask him to state all the facts he took into consideration.

Mr. Wilkerson: I am directing his attention to one specific fact.

Mr. Williams: I object to his attention being directed to every specific item of information.

Mr. Wilkerson: Answer the question.

(The question was here read to the witness.)

A. It affirms the accuracy of the diagram or formula.

Q. What knowledge have you on the subject of the outflow of the Niagara River, as to whether it has been increased or diminished?

A. Alterations in the Niagara River in the vicinity of Niagara Falls, and some slight changes at the head, have tended to increase the discharge capacity of the Niagara River; while on the other hand contraction of the stream above the Canadian Fall has tended to neutralize this effect so that the net result is practically no change in the discharge of the Niagara River, and practically no effect upon the level of Lake Erie.

Q. What is the diversion from Lake Erie into the Welland Canal?

A. I think about 1,200 cubic feet per second.

Q. And into the Erie Canal?

A. That was measured by the Lake Survey under my direction, and was ascertained to be 768 cubic feet per second; the measurement being made in the fall of 1907.

Q. How are those diversions, as compared with what they were before 1890?

A. I believe the Erie Canal diversion is practically unchanged. I am not informed concerning the Welland Canal diversion.

Q. You are pretty familiar with the conditions on Lake Michigan and Huron, I assume, Major?

A. Yes.

Q. That is you have been over them a good deal?

A. Yes.

Q. Now do you know of any outflow from Lakes Michigan and Huron except through the St. Clair River, and what water is diverted at Chicago?

A. I know of none.

Q. What is the generally accepted scientific fact as to that, is there any other?

A. There is no evidence to show the existence of any other outflow.

Q. Suppose there were some subterranean outlet—I put this to you as a hypothetical question—would the fact that the water flowed in or out at a point under the ground make any change in what you have said as to the effect of the diversion of the water at Chicago through the drainage canal?

A. No, it would not.

Q. In other words, would the diversion of that water—

Mr. Williams: I object to the "other words." Let the witness give the other words if there are any.

Mr. Wilkerson: Q. Would that diversion of the water at Chicago remain a fixed factor, which would have the effect that you have indicated upon the level of the lakes?

A. Yes, it would. It has been deduced in view of all facts.

Q. Do you know about the expenditures which have been made in the hydraulic measurements of the St. Clair River?

A. In a general way, I know what time has been spent there and approximately what it has cost.

Q. Let us have a general statement. What I want to get is the extent of the work which has been done, whether there has been much or little, much time or little time spent.

A. Counting the cost of the office reductions as part of the cost of doing the work, I should say we have spent between ten and fifteen thousand dollars in the actual field work of making the discharge measurements. That counts nothing as the cost of the equipment, which is permanently the property of this office, and is used everywhere.

Q. You are familiar with scientific measurements that are made in different departments of research. What do you say as to the maner in which these observations were made, as to the kind of men who made them and the degree of skill and care with which they were made?

A. They were made by men who possessed a high order of engineering skill.

Q. Did they have scientific training?

A. They were men of the highest possible character; men of scientific training, and with a known wish to ascertain nothing but the truth. The measurements were made with no preconceived notions as to what the results should be; and I believe that they are entitled to the very highest credit.

Q. With reference to the measurements on the St. Clair River, take the ones from which these formulae with reference to which you testified are based. Do you know who had charge of that work?

A. Mr. L. C. Sabin, now in charge of the St. Marys Falls canal, had charge of the bulk of the work at the St. Clair River. He is an engineer of the very highest possible standing.

Q. You have had occasion have you to know with reference to his skill as an engineer, and with reference to the kind of work which he does?

A. I know him both personally and professionally.

Q. What would you say on that subject?

A. I regard him as an engineer of the highest possible qualifications.

Q. What do you know with reference to the measurements that were made on the Niagara and St. Lawrence Rivers?

A. Those were made by Mr. Shenehon, who is present. I believe they were honestly and skillfully made, and deserve the utmost credit.

Q. The point that I wanted to have covered, and I think you have covered it already is as to whether it is a fact that all of these measurements and observations were made by men who are men of education in their profession, and men who were trained for this particular work.

Mr. Williams: I object to that question on the ground it is improper for counsel to tell the witness what he desires to have covered in the answer which is about to be made.

Mr. Wilkerson: Answer the question.

A. All the discharge measurements were made by men

who had had a unique training in this kind of work, and who were especially qualified for its performance.

Q. You have come in contact with matters relating to the navigation of the lakes, have you?

A. A great deal, yes.

Q. What have you to say as to whether or not a lowering of the water in Lakes Michigan and Huron, particularly at these points which are characterized as critical points of navigation, to the extent of two inches, would have any real effect upon the navigation of the lakes?

A. I believe it would.

Q. Just what would be the effect? I wish you would explain that somewhat in detail if you can.

A. The draft to which the larger class of vessels may load is directly limited by the depth at what you have called the critical points; that is by the depth at the shallowest places upon the route which they must pursue from their point of departure to their port of destination. In the case of vessels which must pass through the Detroit River, the critical point is at and above the Lime Kiln Crossing. As a matter of fact I know, from my contact with vessel men, that ordinarily they load to the last inch which may safely be carried over these critical points, and that is natural, with a view to earning as much as possible upon each cargo carrying trip. Any reduction in depth at these critical points, therefore, results in a corresponding reduction in the amuont of cargo which may be carried; and the effect is doubly bad because the reduction in the depth of the cargo itself, the depth to which the vessel is loaded, is made at a point where the vessel has the greatest capacity; that is in the upper part of the vessel where it is ordinarily built square, practically like a box. So that a loss of depth has a maximum effect upon earning power. From my frequent conversations with vessel owners and vessel navigators, and personal investigation as to the capacity of cargo carrying vessels, I have ascertained that an inch of draft for the larger class of vessels corresponds roughly to a capacity of 75 tons. So that a loss of two inches in depth of loading is the equivalent of a loss of 150 tons of profitable cargo.

Q. In making the statement that you have made as to the substantial effect upon navigation of this reduction in the quantity of water at these critical points, have you had in mind and given consideration to the fluctuations in the lakes which take place from time to time?

A. I have had those in mind and I know, as a matter of fact, that vessel men are very observant in watching the change in lake levels; the seasonal change is one that they take very close account of, and one which they allow for in their loading. The uncertain changes, those which may be due to barometric effects, they take no account of. Vessels are frequently hung up, as they say, waiting for water at the mouth of the Detroit River, due to what are purely temporary barometric effects. But any reduction due to diversion would be a permanent loss of depth, and would be added to the disadvantages which now arise from the natural fluctuations on the lakes. Such a loss they would have to allow for constantly in the transaction of their business.

Q. In outlining the scope of your present duties, what district was it you said you had charge of?

A. The Grand Rapids Engineer District.

Q. That brings you in contact with navigation on Lake Michigan?

A. On Lake Michigan. It includes all the harbors on the east shore of Lake Michigan proper, with the exception of the harbor of Michigan City.

Q. You spoke of the effect of this permanent lowering at these critical points of navigation of two inches. Are you able, as the result of your observation, to give any specific cases in which vessels have been damaged or where they have grounded, where the injury would not have occurred, if there had been two, four or six inches more of water than there was?

A. There was recently a case of exactly that sort at the harbor of Ludington.

Q. Explain that to us, so that we can see the effect of that, will you, Major?

A. The harbor of Ludington has an authorized depth, that is the depth which we are permitted to create under the law is 18 feet; and ordinarily there is a channel from Lake Michigan into the inner lake at Ludington, which is the harbor of Ludington proper, which affords a depth of fully 18 feet. During the month of April, however, we had a great many southwesterly storms, and as a result of shifting sand, which prevails in the neighborhood of Ludington, and in fact all along the east shore of Lake Michigan, as far north as Charlevoix, at about the middle point between the piers, there was created a very small shoal upon which the minimum depth was found to be 17.2 feet. Now this shoal occurred

between storms, and before the fact of its existence was officially known a vessel loaded with coal, which had come from Buffalo and carried a cargo for the salt works at Ludington went aground in the channel between the piers. Her draft was less than 17 feet forward and a trifle less than 18 feet aft. She remained aground at that spot between the piers, that I have described, for between two and three days. In order to release her, it was necessary to bring the government dredge Gillespie from Frankfort, which is a little over 50 miles north of Ludington, down to Ludington, and pump away a little of this sand, dredge away that sand; and as a result of less than two hours' dredging the steamer was released, entered the harbor, unloaded her cargo and returned to her port of hail to be reloaded. Had there been two or three inches more of depth upon that slight shoal, unquestionably the vessel would have been able to pass over, because the sand was not very compact, and there was not very much of it as was shown by the fact that the dredge by removing less than a thousand yards was able to release the vessel. I think as a matter of fact the dredge moved something like 600 yards before the vessel came off and proceeded into the inner lake.

Q. Would the effect of this proposed diversion at Chicago be felt at Ludington harbor?

A. Yes; not only Ludington, but every harbor on the east side of Lake Michigan, because all of them are in very much the same condition; they have no more depth than they need. Muskegon is a parallel case, where vessels are constantly running aground, due to the lack of merely a few inches.

Q. As a result of your experience in charge of the district with reference to which you have just testified, have you had occasion to give any consideration to the effect upon vessels of introducing a current into a river?

A. Not in that district, I have had no direct contact with the matter of current there.

Q. Where have you ever come in contact with that?

A. Never practically except in the St. Marys River, where in my official journeys as light house engineer I frequently observed that in the large class of vessels the existence of a current of any extent makes the handling of the vessel a great deal more difficult and leads to a great many accidents.

Q. What is the effect upon the tendency to accidents?

A. Oh, it increases largely the tendency to casualties. The worst place upon the St. Marys is known as the Dyke; it is

in what is known as the Middle Neebish Channel, and the trouble there has always been produced by the existence of a very swift current.

Q. You have not had occasion from observation then to know about the effect of the current in the Chicago River with reference to damage to vessels there?

A. Not from direct observation. I am familiar with the facts as generally reported in the annual reports of the Chief of Engineers and as stated by mariners, vessel owners and engineer officers who are familiar with the facts.

Q. Are those facts substantially the same as you stated?

A. Substantially the same; that the presence of a current is a great disadvantage to the navigation of large vessels.

Q. I show you a chart here, which I will ask to have marked Exhibit No. 5 of this date. Tell us what that is, Major, and what you had to do with its preparation, and what it indicates?

A. The chart is a series of diagrams which exhibits the monthly mean water levels of the Great Lakes, as taken from the records of the office of the United States Lake Survey, since January the 1st, 1860. The curves are directly drawn from the measured ascertained levels of the Great Lakes, as derived from gauges upon those lakes. Personally I have had to do with the preparation of these diagrams since early in 1907. It has been republished twice since I have had charge of the Lake Survey office, and in each new edition there has been an addition of the results of the preceding calendar year. We add annually the results of the preceding year to complete it.

Q. You made a like addition each year?

A. Yes. This diagram shows results to January the 1st, 1909. The next edition of this hydrograph will be published early in 1910, and will incorporate the results derived from our gauges for the year 1909.

Q. With reference to the effect of this diversion of the water at Chicago, I omitted to ask you with reference to the effect at different points on the Niagara River. What have you to say on that?

A. The investigations of the Lake Survey made under my direction in 1907 and '8 show that for a foot of fall on Lake Erie the corresponding fall at Black Rock is about .89 of a foot; at Chippewa, it is about a half a foot, and at the Crest of the American Fall it is about $\frac{1}{8}$ of a foot. At intermediate points, it varies in proportion to the values that I have al-

ready stated. I can give more definite values if you wish them, from actual measurements.

Q. I wish you would give that value.

A. The lowering at Austin Street, Buffalo, is .821; at Chippewa .557; Grass Island .556; Willow Island .422; Prospect Point .126; Terrapin Point .238; West end of the Horse Shoe fall .600; at Suspension Bridge it is 2.29 feet, and at the Whirlpool 2.47.

Q. Going back to the measurements which were made by what you have called a current meter, do you know whether or not any tests have been made for the purpose of determining how accurately those meters measured?

A. Yes.

Q. Were they made in connection with your work here?

A. No, the tests were made by this office but before I assumed charge of it. They were made in 1906; I assumed charge of the office in 1907.

Q. Without going into the details as to the results which are shown, I wish you would tell us in a general way how those tests were made?

A. The tests were made in the Detroit River, a short distance below here upon a measured base of 200 feet. At the upper end of the base, about a foot below the surface, a water meter was suspended, and at the lower end of this base another meter was suspended, and the records of both meters were taken. At the same time there was released above the upper meter and suitably timed upon this base, a series of globules, or globes of colored water. These were injected into the stream with a syringe, and it was found that they preserved their form in well defined fashion for the entire length of the base, so that the exact moment of their crossing the upper end and the lower end of the base line could be timed. As a result, the actual velocity of the water could be derived from the velocity of these colored balls of water, and compared with the velocity as derived from the current meters themselves, suitably rated. The tests were, I believe, about seventy-two in number.

Q. Who had charge of the details of the tests?

A. Mr. Shenehon who is present.

Q. And who will be able to give the facts in detail with reference to that?

A. Yes.

Q. Generally what was the result?

A. A practically exact correspondence in velocity, as meas-

ured in the water itself and as measured by the current meter; the only difference existing in the third place of decimals for the average. I mean that the velocity was less than three feet, it was about 2.9 feet, and the difference as measured was in the third place of decimals.

Q. For what purpose were those tests made; that is to say, what connection did they have with the Lake Survey work?

A. There had frequently been made in published articles here and elsewhere an assertion that the operation of rating the meters did not give a true statement of the velocity which the meter was supposed to measure, because the meter when measuring velocity in the stream was stationary and the water moved with respect to it; whereas in rating the meter, the meter was drawn through the water and the water was stationary. That is to say the effect of the water on the propeller wheel of the meter must necessarily be different because of the difference in the two sets of conditions. And these tests were made to ascertain what merit there was in this statement. The result showed there was no merit whatever in the contention.

Q. What did I understand you to say the test showed?

A. The test showed that the velocity derived from meter measurement upon discharge work actually determined the velocity of the water.

Q. That was from a series of how many observations?

A. I think it was seventy-two. It was over seventy.

No cross-examination.

Recess to May 25th, 1909, at the hour of 9:30 o'clock a. m.

May 25, 1909, 9:30 o'clock a. m.

SHERMAN MOORE, called as a witness on behalf of the Government having been first duly cautioned and sworn, testified as follows:

Direct Examination by Mr. Wilkerson.

Q. What is your full name?
A. Sherman Moore.
Q. Where do you live?
A. 316 Lincoln Avenue, Detroit.
Q. What is your occupation or profession?
A. I am a civil engineer.
Q. Where were you educated?
A. At the University of Wisconsin.
Q. When did you graduate?
A. I graduated in 1902.
Q. Do you hold any degrees?
A. I have the degree of Civil Engineer given in 1907 by the University of Wisconsin, in addition to degree of Bachelor of Science given at graduation.
Q. Any other?
A. No, sir.
Q. What has been your experience as an engineer, what work have you done?
A. I have been employed by the Lake Survey since June, 1902, on survey work, on triangulation; and during the past three years almost exclusively on hydraulic measurements.
Q. Have you had anything to do with hydraulic measurements on the Niagara River?
A. Yes, sir.
Q. When did you make those measurements?
A. 1907 and '8.
Q. What kind of measurements did you make?
A. They were measurements of the discharge of the river made from the International Bridge.
Q. Go ahead now and tell us just how you made those measurements and for what purpose they were made?
A. The measurements were made for the purpose of determining the effect on Lake Erie of water diversions at Niagara Falls for power purposes.
Q. How did you make them?
A. The measurements were made with the Haskell cur-

rent meter, observing at the index points established in 1899, 1900.

Q. You say they were made by the Haskell current meter. Describe to us briefly and concisely how you make the measurements with that meter?

A. On the Niagara River we did no coefficient work at all. We observed index velocities, velocities at two or three points in each span, and the reduction was made with the coefficients determined in 1899.

Q. How do you measure this velocity with the meter?

A. In the measurements of the discharge of a river, the procedure is first to divide the river into sections of such a size that the current velocities may be considered as proportional to each other. Ordinarily in an open river of large size, we use about a hundred feet. In that space the transverse curve of velocities, that is the distribution of velocities across the river, is not great; and the velocity at any point in that section may be considered as a percentage of the velocity at any other given point which may be taken as the index for that section. At the International Bridge, there were two and three sections in each span. The water passing in a given time through a section, if it was solidified may be conceived as a solid of which four sides would be planes; that is the surface, the back and the two sides limiting the section under consideration. The front would be curved, depending on the distribution of the velocities in the vertical. That is, the velocity at the surface is not the same as it is at the bottom, and the front would be a warped surface. There is a transverse coefficient coming in to a slight extent. In ordinary work on a river, that curve is so slight that ordinarily it would be neglected. Determining the volume of this solid, if we may speak of it as such, is very similar to determining the volume of any solid of irregular size. We measure the ordinates in a vertical plane through the center of the section, ordinarily. The method employed is the two meter method. One meter is placed at the index point, to which the velocities are later referrd, and the other meter traverses the vertical curve, measuring the velocity at the surface at each tenth depth, and also at the bottom. The two meters are run simultaneously and the results are reduced by considering the velocity given by the traveling meter as a percentage of the simultaneous velocity given by the meter at the index point. In that way the vertical velocity curve may be drawn, platting the percentage velocities with respect to the

percentage depths. The mean ordinate to this curve is the mean velocity; the transverse curve, if it is considered, is obtained by platting the index and sub-index velocities for a large number of measurements, with respect to the distance from either side, and drawing through these points a smooth curve. Then the transverse velocity coefficient for any section, or sub-section, will be the mean ordinate to the transverse curve divided by the ordinate at the index point. The product of the vertical velocity coefficient and the transverse velocity coefficient is the velocity coefficient for the panel. The velocity as measured at the index multiplied by this velocity coefficient gives the mean velocity in that panel. The produce of the area of the panel in square feet as determined by soundings, and the index velocity in feet per second multiplied by the velocity coefficient is the discharge through the panel. The summation of all the panel discharges makes up the discharge of the river.

Q. What was the result of these measurements of the Niagara River that you made at the bridge? I refer now to the determination of what we call the increment, in connection with this matter?

A. The measurements in 1907 and '8 checked almost exactly with the measurements made in 1899.

Q. Do you know who made the measurements in 1899, so that we will have them identified here?

A. They were made by Mr. F. C. Shenehon.

Q. You say they checked almost exactly with those?

A. Yes, sir.

Q. How many measurements did you make?

A. I made 126 measurements.

Q. And when did you commence to make them?

A. The first measurements were made in October, 1907. Measurements were made during October and November of that year, and in 1908, in June, July and August.

Q. You say they checked almost exactly with Mr. Shenehon's measurements. What was the increment as you derived it?

A. The increment at mean stage is 22,000 cubic feet for one foot on Lake Erie.

Q. Did you make any soundings of the Niagara River in connection with these measurements?

A. The section at the bridge was sounded in the first four spans on the American side.

Q. What was the result of those observations?

A. The soundings showed absolutely no change in spans 1, 3 and 4, and a scouring out in span 2 amounting to between 15 and 20 per cent increase in area.

Q. What were the conditions in that span which caused this scour?

A. The bottom, in spans 1 and 2, is a deposit of silt. A short distance above the bridge, prior to 1907, there had been quite extensive dredging close to the shore, and this probably resulted in a slight increase of velocity, which scoured out the span. The bottom in the other spans is bed rock, and showed no change.

Q. A little more in detail about these soundings in spans 3 and 4. Have you the result of your work there?

A. You mean in regard to the results or the method of measurement?

Q. Just what were your soundings on spans 3 and 4? You say they showed no change?

A. They showed no change.

Q. About how deep was it in those places?

A. In span 3 the depth is, mean depth, about 28 to 30 feet; maximum depth of about 36 feet. In span 4 the mean depth is 42 to 43 feet and the maximum depth is 48 feet.

Q. What was the velocity of the water at this place?

A. The velocity was high, ran in the neighborhood of six to seven feet per second.

Q. How did you make those soundings, will you give us the method, Mr. Moore?

A. The soundings were made by means of a cast iron weight, which was of the projectile type, a sphere drawn out into cones on each end, with a wooden tail to hold the nose of the weight in the line of the current. The weight used there was 135 pounds. It was suspended with steel piano wire, a little less than one-tenth of an inch in diameter. This wire was carried on the drum of a reel which rested on the chord of the bridge. The circumference of the drum was exactly three feet, and the depth was determined by the revolutions and partial revolutions of the drum. In spans 3 and 4, the velocity of the current was so great that in order to bring the weight to the bottom in the plane of the section, it was necessary to cause the wire to enter the water about four feet above the line of the section. This was done by a heavy weight, which carried a hook which engaged the sounding wire. The auxiliary weight was suspended from the down stream chord of the bridge, and a guy line was run to the

up stream chord of the bridge, so that the weight and the sounding wire could be pulled back up stream any desired distance. The angle of inclination of the wire did not exceed 18 degrees; it was usually much less. The weight was lowered to the water surface, and the reading of the circumference of the drum was taken with the weight just touching the water surface. Then it was lowered to the bottom, and a second reading on the drum was taken. The weight was then raised just clear of the bottom, and the angle which the wire made with the vertical was measured. The difference between the two readings corrected for the inclination of the wire, was the sounding; gave the depth of the water. It was referred to a fixed plane by the readings of a gauge on the shore.

Q. Did you make any measurements on the St. Lawrence River?

A. Yes, sir.

Q. When?

A. In September and October, 1908.

Q. For what purpose?

A. For the purpose of determining the effect of changes which had been made in the river since the former measurements were made.

Q. Were those soundings?

A. The hydraulic section was sounded, and twenty-six measurements of the flow were made.

Q. What was the result of those observations?

A. The observations showed that the flow of the river had been decreased about 5 per cent for a given stage of Lake Ontario.

Q. What change had been made in the river, the effect of which it was your object to determine?

A. The greatest change was due to the construction of what is known as the Gut Dam. That is a dam between two islands at the head of the first rapids in the river, the Galops Rapids, which was built in 1903, I think, for the purpose of facilitating vessel navigation.

Q. Do you know whether there had been any estimate or computation made with reference to the effect of that dam?

A. Yes, sir, there has been.

Q. Was there any before you made the measurements?

A. Yes, sir.

Q. Based upon this method of determining the relation

that you have described. What was the estimate and who made it?

A. It was made by Mr. Shenehon.

Q. And what was it?

A. It was 5½ per cent.

Q. That would be the effect of the construction of the dam?

A. Yes, sir.

Q. How closely did your observations tally with that computation, if you know?

A. They checked exactly as near as could be determined.

Q. That is they showed the change up to 5 per cent?

A. Yes.

Q. That had been estimated on this method of computation?

A. Yes.

Q. What effect did that change, about which you have just testified, at this dam have upon the increment?

A. The change in the increment from the discharges made last year, cannot be determined. The discharges cover a range of stage of only one-half foot at Ogdensburg.

Q. Having in mind now these observations which you made and your experience, what do you say with reference to the increment of the St. Lawrence River? I am referring to this point at which you made your measurements?

A. It is between twenty-eight and twenty-nine thousand cubic feet for a foot on Lake Ontario.

Q. Does that take into consideration this 5 per cent change about which you have just testified?

A. Yes.

Q. That is to say would the effect of that be to make the increment greater or less?

A. The effect would be to make the increment less.

Q. And you have taken that into consideration in your statement of twenty-eight or twenty-nine thousand?

A. That is my impression of it. I do not remember the exact figures.

Q. That is within how close, do you think, as you have stated it? Is there anything to which you can refer to give an accurate statement?

A. For a stage at Ogdensburg of 245 feet above mean tide, the increment is about 28,000; it is that within one or two per cent.

Q. What measurements if any have you made on the St. Clair River?

A. In November and December of 1908, I made fifteen measurements of the flow of the river on Section Dry Dock, and twenty-two measurements of the flow on a new section, at the head of the river.

Q. What was the purpose of those observations?

A. To determine whether or not there had been any change in the conditions governing the outflow from Lake Huron.

Q. What did you find?

A. The observations on section Dry Dock, which is the old section, showed practically no change.

Q. You measured a new section?

A. Yes, sir.

Q. What was the purpose of that?

A. To furnish a check on the measurements on the old section.

Q. That is to say for the purpose of verifying the computation which had been made with reference to the relation between lake stage and outflow?

A. Yes, sir.

Q. And as a check on the increment as it had been determined by former observations?

A. Yes, sir.

Q. Will you describe a little more in detail the measurements on this new section which you made; tell us a little more in detail just what you did there?

A. The new section which is known as section Gorge, is located about a quarter of a mile from Fort Gratiot Light House, just above the narrowest point in the river. The section is a thousand feet wide.

Q. Is that a comparatively wide or narrow part of the river?

A. It is a comparatively narrow section. The narrowest point is about 800 feet wide. This section is just above it.

Q. Was that a section which was favorable or unfavorable for the purpose of making discharge measurements?

A. I consider the section exceedingly favorable.

Q. Why?

A. The velocity averages between five and six feet per second. The current threads are steady and slightly converging and the velocity is accelerated. Under those conditions, there exists very little boiling or broken current threads; the current threads run very smoothly.

Q. In that connection did you make any measurements with water gauges?

A. During the measurement of the discharge, gauges were maintained at a point about a mile and a half above Fort Gratiot light, and at various points in the river below the section, and a gauge on the section.

Q. How did you make the readings? Describe that. And I assume that what you say as to the readings of the gauge on the St. Clair applies also to the measurements of the Niagara and St. Lawrence?

A. Yes.

Q. How did you make those measurements?

A. The gauge used on the river work is what is known as the small type automatic gauge, designed by the Lake Survey office. It consists of a drum about four inches in diameter driven by a clock. On this drum are needle points every two inches, which engage a roll of paper three inches wide, which passes from a spool on one side over the drum on to a receiving spool on the other side, at the rate of two inches each hour. The elevation of the water surface is recorded as a continuous line on the paper, by means of a float in a box which is attached to a wheel about four inches in diameter, geared to a pencil which moves across the paper. The elevation of a fixed line on the paper is determined by readings of a staff gauge, taken usually once a day. This staff gauge is ordinarily a small box about four inches in square set into the water, in which floats a bottle carrying a graduated staff. The elevation of the top of the box is determined by levels from known bench marks, and the gauge reads distances below the top of the box. These elevations by the staff gauge fix the elevation of a fixed line on the paper, and elevations at any other time are scaled from this line to the stage line.

Q. Where did you say you had these gauges?

A. There was an automatic gauge at Muronia Beach, about a mile and a half above Fort Gratiot Lighthouse; a gauge at the old Ferry slip of the Grand Trunk Railroad, about three-quarters of a mile I think below the section; another gauge at the old Dry Dock of Dunford and Alverson, about three miles below the city; a gauge at Roberts Landing and a gauge at St. Clair Flats ship canal. In addition, during all measurements of the flow, there was a staff gauge read at five minute intervals at Fort Gratiot Lighthouse. There was also an automatic gauge on the section which gave the elevation of the water at that point.

Q. What was the result of these observations which you made at this new section, as to the increment which you determined, as to comparison with the former observations?

A. There are in existence a great many formulae for the flow of the St. Clair River. Comparing the observations on section Gorge with what are probably the best of these formula, the results there in 1908 showed between one and a half and two per cent smaller than indicated by the formulae. Considering the results by themselves, the increment of flow for normal stage of Lake St. Clair is between 20,000 and 21,000 cubic feet per second.

Q. Have you, as a result of this work which you have been doing for the last two, or three years, had occasion to reach a conclusion with reference to the precision of the observations which are made from current meters?

A. Yes, sir.

Q. What do you say on that subject?

A. The velocities as given by the Haskell meter, which we have used in all of our work, are unquestionably true velocities.

Q. Why do you say that?

A. In 1906 on the Detroit River tests were made of the velocity as given by the meters compared with the velocity of the river as given by floats.

Q. Did you have anything to do with those tests?

A. I did.

Q. What did you have to do with them?

A. I recorded all the observations.

Q. So you were on the ground, or the water, all the time?

A. Yes, I recorded the observations.

Q. Describe in detail how you made those tests and what the result of the tests was?

A. Two steel catamarans such as were used in the pontoon sweep, used at one time by the Lake Survey, were suspended in the current of the Detroit River; the upper one fastened to an anchor in the bed of the river and the lower one suspended 200 feet below it by means of two galvanized iron wires. These wires were very carefully measured and were marked at the exact distance of 200 feet. On each catamaran, suspended by an overhang so that the meter ran at least six or seven feet to one side of the hulls, so as to be beyond the influence of the hull, there was suspended a current meter. The floats used consisted of balls of bluing, which were injected into the water by means of a bicycle pump.

Floats of this character, forming part of the water itself, unquestionably give the true velocity of the water. A float was started several feet above the first meter, and as it passed the first meter, both meters were started by one movement. As the float passed the second meter, both meters were stopped. The relation was determined between the velocity of the current as given by the colored balls of water and the mean of the velocities given by the two current meters which had been rated in still water, both before and after the tests. There were seventy-six tests made, and the result showed that the indications of the meters agreed with the velocity of the water by about one-fifth of one per cent.

Q. Have you any other reasons for reaching the conclusion which you have stated with reference to the accuracy of the measurements made by this Haskell current meter?

A. The precision of the measurements themselves has been tested in several cases by the measurement of two sections on the same stream.

Q. Have you had in your own personal experience occasion to do that?

A. Yes, sir.

Q. Where?

A. On the intake canals of the power companies at Niagara Falls.

Q. Tell us what you did there and what the result of that work had to do with your statement as to the accuracy of these current meter measurements?

A. The intake of the Niagara Falls Power Company is between 175 and 190 feet wide, 180 feet at the point of measurement; with a depth of about 12 feet and a velocity of about four feet per second. Two sections were measured on this canal in 1907, one about a hundred feet below the other with slightly decreased width and increased velocities. The two sections showed the same discharge by one-half of one per cent. The intake canal of the Niagara Falls Hydraulic Power & Manufacturing Company is about 120 feet wide and from 16 to 20 feet deep with velocities ranging from one and a half to three feet per second. Two sections were measured in that canal, one from a bridge spanning the canal near the lower end, and one from a cable-way near its upper end. The two sections were separated by over a quarter of a mile. The flow as measured by the two sections agreed by 1.7 per cent. This canal did not offer the best facilities for current meter work on account of dredging work which was going on in the

canal at the time, and the continual passing of a tug back and forth, which broke up the threads to some extent.

Q. How did you compare these two sections, were the measurements taken simultaneously?

A. On the canal of the Niagara Falls Hydraulic Power & Manufacturing Company, simultaneous measurements were made for eight hours. On the canal of the Niagara Falls Power Company, as both sections were determined from cableways, simultaneous measurements could not be made. The check between the sections there is obtained by the indications of a meter run at a point in the head of the canal from a conveyor which carries pulp wood to the paper mill, crossing the canal at its head. This meter was run continuously during all the measurements, and suitable coefficients were derived to give the discharge through the canal in terms of the velocity by this meter. The check between the two sections is the check between these coefficients at a given time. With a given velocity at the meter of the conveyor, the product of the coefficient for Section 1 by the area of the section must equal the product of the coefficient for Section 2, by the area of that section.

Q. Have you done any other work that bears upon the question of the accuracy of these current meter measurements?

A. The measurement of the new section in the St. Clair River indicates the accuracy of the work.

Q. Why?

A. The two sections there are exceedingly different. The lower section is about two thousand feet wide, the upper one only a thousand. The velocity in the lower section is about three feet per second, and in the upper section nearly six. The depth in the lower section lies between twenty and thirty feet; the depth in the upper section reaches sixty-five feet. The sections were measured by different observers at different times, and yet the results agree within less than two per cent.

Q. Do you recall anything else in addition to that about which you have testified, which bears on this matter of the accuracy of those measurements?

A. On the Niagara River, in 1898 to 1900 two sections were also measured. These sections were very different; one was a section from the International Bridge, broken up by the bridge piers, with eddying around the piers to a large extent. The other was an open section half a mile further down, where

the water was running smoothly. The measurements on the two sections agreed by about 1.3 per cent.

Q. What does that indicate to you as an engineer?

A. The tests made in the Detroit River indicate that the Haskell meter gives true velocities, and the agreement of two sections on various streams indicates that the method of measurement, the use of the instruments, gives accurate results.

Q. What do you say as to the accuracy of the soundings? Have you any way of checking soundings on cross sectional areas?

A. The accuracy of the soundings is as great as the accuracy of the measurements of velocity.

Q. Why do you say that?

A. The soundings made by different observers at different times at the International bridge, in spans 3 and 4, under extremely difficult conditions showed absolutely no change in the cross sections. Soundings made on the St. Lawrence River in 1908, at the same points at which soundings were made in 1901, showed absolutely no change in the cross section. Soundings made on Section Dry Dock in the St. Clair River in 1908 checked exactly with the result of earlier work.

Q. What do those facts indicate to you as an engineer?

A. The facts show that the soundings as made are correct to at least within one per cent.

Q. You have given evidence here with reference to the measurement of these velocities and the determination of these increments. What have you to say as to the problem there presented as compared with the problem of measuring earth works for instance, as to whether as a matter of engineering it can be done so as to get any accurate result?

A. I consider the measurement of stream flow, so far as the process is concerned, just as simple and sure as the measurement of earth work. It requires a little more observation, but the process is exceedingly simple.

Q. Did you make any observations with reference to the scour in the St. Clair River?

A. Yes, sir.

Q. When?

A. In the fall of 1908.

Q. And how were those observations made, what was your method?

A. In 1897 and '8, four cross sections were laid out in the rapids at the head of the St. Clair River and established by

monuments at the ends. These sections were sounded in 1898, 1899, 1901, 1904 and 1908. The measurements in 1908 were made by me. The results of those measurements showed that there has been no scouring out of the bottom in that portion of the river to any appreciable extent. There have been minor changes on the four sections, but considering the four sections together, there is no scour shown. On the upper section, the soundings of 1908 show an increase in the depth.

Q. Which section is that?

A. That is the upper of the four sections, established in 1898.

Q. Does that have a name?

A. Section Culvert; it shows an increased depth of about 1.3 feet since 1901. On the second section, section Fish, there is no change in the area shown by the soundings of 1908. On Section Arthur, the third section, since 1901 there appears to be a filling in of about two and a half feet. This is probably due to a wreck which lies just above the section and reduces velocities near the bottom. On section Stauber, which is the fourth section, there is no change shown since 1901; the two areas are identical.

Q. Did you measure the flow in the Erie canal?

A. Yes, sir.

Q. When?

A. 1907.

Q. What was the result of those observations?

A. The flow through the Erie canal at the time of the measurements was about 800 cubic feet per second, between seven hundred and eight hundred cubic feet per second.

Q. As the result of your observations and the study which you have given to this subject, are you able to make any statement with reference to the relation which exists between the level of Lakes Michigan and Huron and the outflow of the water through the St. Clair River?

A. The relation between the flow through the St. Clair River and the elevation of Lakes Michigan and Huron has not changed since the measurements made in 1898.

Q. What do you state the increment to be?

A. For normal conditions of the lakes, the increment is between twenty-three and twenty-four thousand cubic feet per second, for a foot change on Lake Huron.

Q. What do you say with reference to the relation which exists between the elevation of Lake Erie and the outflow through the Niagara River?

A. The flow through the Niagara River with respect to the elevation of Lake Erie is exactly the same as it was in 1899.

Q. And what is the increment?

A. The increment for mean stage is 22,000 cubic feet per second.

Q. That is in round numbers?

A. In round numbers.

Q. If water is diverted from Lakes Michigan and Huron at some other point, what will be the ultimate effect upon the quantity of water which flows out through the St. Clair River?

A. The quantity will be decreased.

Q. Why do you say that?

A. The opening of a second outlet to any body of water is certain to lower the level of that body of water, and the lowering of the level of the lake—

Q. Do you state that as an established, recognized, scientific fact?

A. Yes, sir.

Q. Unquestioned?

A. Unquestioned.

Q. Go ahead?

A. The lowering of the level of the lake means a decrease in the outflow of the river.

Q. From the observations you have made and computations which are based on those observations, what do you say as to the effect of diverting 4,000 cubic feet of water per second from Lake Michigan at Chicago, upon the elevation of Lakes Michigan and Huron?

A. The elevation of Lakes Michigan and Huron would be lowered about two inches.

Q. At one point or all the points?

A. At all the points.

Q. At all the channels and harbors?

A. Yes, sir.

Q. What would be the effect of that diversion upon the level of Lake Erie?

A. Of 4,000 cubic feet diversion?

Q. Yes.

A. The effect would be slightly over two inches.

Q. What would be the effect on Lake Ontario and the St. Lawrence River?

A. The effect would be a little less than two inches on Lake Ontario.

Q. And would the effect of diverting other quantities be in proportion to the figure which you have given for the diversion of 4,000 cubic feet?

A. Yes, sir.

Q. That is if ten thousand were diverted instead of four thousand the lowering would be in the ratio of ten to four?

A. Yes, sir.

Q. And so on for other quantities?

A. Yes, sir.

Q. Did you make any observations, with reference to the water power at Niagara?

A. I measured the amount of water which was being used for power by the Niagara Falls Power Company, and by the Hydraulic Power & Manufacturing Company.

Q. How did you do that?

A. The measurements were made in the intake canals of both companies, in the same manner in which the flow through any stream is measured, as I have explained earlier.

Q. What is the head at Niagara, head of the water?

A. The Niagara Falls Power Company uses about 143 foot head; the head of the Hydraulic Power & Manufacturing Company is about 200 feet.

Q. Translating that into horse power in a cubic foot per second, what is the figure?

Mr. Williams: I object to that. I do not understand the diversion of 4,000 cubic feet a second at Chicago, or any other amount, is going to change the head, or interfere with the operations of these power companies, and if it did, this suit is not brought for the protection of the power companies.

Mr. Wilkerson: Q. Do you understand my question?

A. You want the—

Q. How many horse power in water of that head is there in a cubic foot?

A. The Niagara Falls Power Company generates about 65,000 horse power from about 8,000 cubic feet. That would be about 37,000 horse power for 4,000 cubic feet. The Niagara Falls Hydraulic Power & Manufacturing Company develop a greater amount than that.

Q. Will you check your figures on that, Mr. Moore?

A. About 32,500 for about 4,000 cubic feet.

Recess to 1:30 p. m.

1:30 o'clock, p. m., May 25, 1909.

SHERMAN MOORE, resumed the stand and testified further as follows:

Cross-Examination by Mr. Williams.

Q. Mr. Moore, what would you say as to the possibility of error in the reading of these Haskell Meters, or in the meters themselves?

A. The error of observations with a meter is less than one per cent.

Q. That is the error of observation?

A. That includes the error of rating the meters.

Q. Would there be a possibility of the meter indicating a greater velocity than actually existed?

A. By very small amounts.

Q. What circumstance or situation might cause a meter to indicate a higher velocity than actually existed?

A. The rating of the meter is not absolutely constant but is dependent upon a great many things inherent in the meter itself. Wear on the pivots has some effect; but it has been found that unless some accident accurred to the meter, the difference between two consecutive ratings was ordinarily very small. A single observation might be an error by as much as two per cent; but by the combination of more than one meter, and none of our results are based on one meter only, such errors are largely eliminated.

Q. By taking one meter alone, what situation might cause that one individual meter to indicate a greater velocity than actually existed? Are there any situations that come to your mind readily?

A. The substitution of a new contact pin in the meter will ordinarily for a short time cause the wheel to turn slightly harder, if this occurred at the time of rating the meter it will indicate a greater velocity than actually existed, but the change is very slight.

Q. Does the direction of the current, and the way the current happens to strike the meter have anything to do with it?

A. The meter is so built that the current always strikes the meter square.

Q. So that you would say that the possibility of a meter

recording a greater velocity than actually existed would be very slight?

A. Yes.

Q. What would you say as to the possibility of a meter indicating a less velocity than actually existed?

A. A meter would be just as likely to indicate a less velocity as a greater velocity.

Q. Not any more likely?

A. No more likely.

Q. Are there any situations that you can think of that would cause such a result?

A. The pivot on which the wheel spins is occasionally sharpened, and after the pivot is sharpened, it takes a few days for the pivot to wear smooth. During that period there would be a very slight variation.

Q. If there should be a temporary interference by a small amount of weeds or string or anything of that kind that would wrap around the pivot, would that have any effect temporarily?

A. If such a thing occurred, it would. The meters, however, are inspected so frequently that any condition of that kind could not exist for more than an observation at a single point.

Q. An interference of that kind lasting only a very short time would indicate a less velocity than actually existed, wouldn't it?

A. Yes.

Q. Would cause the indication of less velocity?

A. Yes.

Q. Is there any way you can guard against those things occurring except by frequent inspection?

A. The meter wheel is so built that it is designed to throw off anything of that kind and in my experience, with one exception I think, I have never found anything of the kind on the meter. In the canal of the Niagara Falls Power Compay, late in the fall, there was an enor ous mass of dead vegetation floating in the water, and at times that would wrap around the meter. I have never seen it anywhere else.

Q. Did you testify as to the effect in the St. Lawrence River of the diversion of water at Chicago?

A. Of the effect in the river? No, sir.

Q. The St. Lawrence River?

A. No, sir.

Q. How frequently did you find the effect of these weeds in the power canal?

A. It was only on two or three days which followed severe storms.

Q. Well, how frequently did you find the weeds interfering with the efficiency of the meter?

A. The weeds were removed from the meter about once every thirty minutes.

Q. And how many times?

A. During these—I think there were three days.

Q. Every thirty minutes for three days?

A. Yes.

Re-direct Examination by Mr. Wilkerson.

Q. I think you said you never had any experience with weeds except at the one place?

A. Yes.

Q. That was on the Niagara River?

A. Yes.

Q. Was there a bed of weeds in the river above where you made the observations?

A. Yes, sir.

Q. Very thick?

A. Yes, sir, very thick.

Q. And the effect of the storm was to loosen those?

A. Yes.

Q. What did you do with those observations, when you found the weeds?

A. They were all rejected.

Q. You didn't take those into consideration at all?

A. No.

Q. And they do not enter into this result about which you testified?

A. No.

Q. You did not have any trouble with weeds in connection with any of these other observations about which you testified?

A. No, sir.

Q. In either the St. Clair River or any other place concerning which you testified?

A. No, sir.

Q. Take the measurements in the St. Clair for instance,

was there anything present there which interfered with the operation of this meter, weeds?

A. There were no weeds there whatsoever. At times after a storm, when a meter occupied a position close to the bottom of the river, there was a little sand.

Q. Could you detect that situation?

A. Yes.

Q. What did you do with those observations?

A. Those observations where it was known that it occurred were rejected.

Q. What about your detecting them in that situation, did you watch for it closely?

A. Yes, it was watched for closely and the meter was examined each time after it had been to the bottom, and thoroughly cleaned so that the condition was remedied.

Re-cross Examination by Mr. Williams.

Q. What would be the effect upon the accuracy of your measurements of the passing of boats in the channel?

A. I have been unable to detect any effect in the observations.

Q. Is it your opinion then that the passing of boats at the time you were making your observations would not affect the accuracy of those measurements?

A. I do not think that the passing of boats did affect the accuracy of any of the measurements.

Q. There were boats passing through the channel during the time that you were making your measurements, were there not?

A. There were a few.

Q. When was it that you made these measurements in the St. Clair River?

A. Last November and December.

Q. How many days were occupied in making those measurements?

A. The measurements of the discharge of the river were made on nineteen days on the upper section.

Q. How many days were occupied on the other section?

A. Measurements were made on eight different days.

Q. Will you give us the dates on which you made the observations on the upper section?

A. On November 18, 27, 28, December 1, 2, 4, 9, 10, 11, 12, 15, 16, 17 and 19.

Q. What were the dates of your observations on the other sections?

A. November 7, 9, 10, 11, 21, 23, December 14 and 18.

Further Re-direct Examination by Mr. Wilkerson.

Q. Counsel asked you about passing boats. Were there many passing boats at the time you made these observations?

A. There were very few passing boats.

Q. Why?

A. Both on account of the lateness of the season and the unfavorable year for vessel commerce.

Q. I am not quite sure that I understood your answer as to the effect of a new pin on this meter.

A. The construction of the meter is such that each revolution of the wheel makes and breaks an electric circuit which operates a counting register at the surface. The contact is made on the back end of the wheel. There is a disc, half of it is hard rubber and half of it is silver, and bearing on this disc with a very slight pressure is a small silver headed pin which is insulated from the body of the meter. The pins wear out, and it is necessary occasionally to replace them. When a pin is replaced, it is ordinarily slightly longer than the old one which was removed, although an attempt is made to get the pressure as nearly uniform as possible. Any change from that cause is very slight, however.

Q. If the pin presses a little harder does it make the meter indicate a greater or less velocity?

A. It makes the meter indicate a greater velocity. I am mistaken; it would indicate a less velocity.

Q. Maybe I can clear that up. Does it make any difference in the result whether the pin is changed when you are rating the meter or when you are making these measurements?

A. When the pin is changed the pin is ordinarily changed during the rating, so that the rating is made under the new conditions. Occasionally it is necessary to change the pin during the measurements.

Q. Is there any difference in the result when the change is made in the rating or in the making of the observation; if so what?

A. When the change is made at the time of the rating,

the velocities are too large as the new condition is embodied in the rating.

Q. How often do you rate the meter?

A. Meters are ordinarily rated about—well the time varies. On the Niagara River work, the meters were rated about once a month. On the St. Clair River work, the meters were rated before beginning the work and after the work was completed.

Q. How many meters did you use?

A. We used four meters.

Q. In both pieces of work?

A. On the St. Clair River, and three meters on the Niagara River at one time.

Q. Did you make any tests from day to day which would indicate the rating of the meter?

A. On the Niagara River, at least once a week the meters were run side by side in the channel, and simultaneous observations obtained, which showed any change in the rating of any meter.

Q. That is there was a check?

A. Yes.

Q. A check among the meters?

A. Yes. On the St. Clair River every measurement of a vertical curve gave a check on the rating of the two meters employed, by observations when running at four-tenths depths side by side.

Q. Did you make any spinning tests, spinning the meter out of the water?

A. Once a day it was customary to spin the meters in the air and record the number of seconds they would run. The test is ordinarily made in the morning after the meters were cleaned, the first thing in the morning.

Q. Let me put this question to you: just tell us all the precautions you took to see that the meters remained in condition?

A. I didn't catch your question.

Q. You started out to state with reference to one precaution that you took to see that the meters remained in good condition. Go ahead with that and state any other precaution that you took to check up on these meters and see that they remained in condition?

A. The meters were always handled with extreme care. They were cleaned and oiled by one of two men; that is the cleaning was confined to two men, so that it was as nearly uni-

form as possible. Spinning tests in the morning indicated any abnormal condition in the meter. Current meter tests weekly on the Niagara River, and five and six times a day on the St. Clair River, showed up any temporary abnormal condition in the meter. And the meters were very carefully examined each night for any unusual condition in wear on the sides of the body, or anything which would interfere in their holding the rating. They were watched as carefully as it was possible to watch them.

Mr. Wilkerson: That is all.

F. G. RAY, a witness called on behalf of the Government having been duly cautioned and sworn, testified as follows:

Direct Examination by Mr. Wilkerson.

Q. What is your name?

A. F. G. Ray.

Q. Where do you live?

A. Detroit.

Q. What is your occupation?

A. Civil engineer.

Q. How long have you been engaged in that occupation?

A. I graduated from the State University of Iowa in 1892; and I have been engaged in civil engineering work since then.

Q. In a general way, what work have you done since 1892?

A. I was engaged with the Mississippi River Commission, from the fall of 1892 until 1900. Since then I have been engaged with the Lake Survey.

Q. What has been the scope of your work on the Lake Survey?

A. I have had charge of field parties on triangulation, hydrography and topography during the summer seasons; and have been employed on reduction of notes, water levels, hydraulics, etc., in the winter.

Q. Have you done any work in connection with the determination of what you call critical areas on the lakes?

A. Our field work has been principally an examination of critical areas.

Q. What do you mean by critical areas?

A. Areas that show depths that are or are suspected to be dangerous to navigation; and investigation of channels where the navigable depths are narrow and close.

Q. What particular critical areas have you investigated? Start in with the lower end of Lake Michigan, for instance, and come around?

A. Last season I made a survey of the south end of Lake Michigan, extending from the vicinity of Gary to the mouth of the Chicago River.

Q. What was the nature of that work, what were you trying to find out?

A. It was principally sounding and sweeping for shoals, wrecks and other obstructions to navigation.

Q. Did you find any shallow places down there?

A. We found a number of shoals in the vicinity of Indiana Harbor, that were not charted correctly.

Q. What did you find? State specifically the facts that you found with reference to those shoals?

A. You mean the nature of the shoals?

Q. Yes, and how deep the water was; what limitation, if any, they imposed on the draft of vessels. You are referring, to refresh your recollection, to some chart or map?

A. This is a chart of the last season's work.

Q. That you caused to be prepared?

A. That I caused to be prepared.

Q. Refer to that now, refresh your recollection and just give us the facts with reference to those shoals?

A. There is a series of irregular sand shoals, hard sand bottom, lying off in a northeasterly direction from Indiana Harbor, extending out some five or six miles, in which the prevailing depths are from 16 to 18 feet.

Q. Of what extent are those depths of 16 to 18 feet, for how much of the lake?

A. The area of shallow water is very irregular. There are several parallel reefs that are from one to two miles long, extending about north by west and south by east in direction. There is deep water between them. These shoals start near the shore and extend, as I said before, out about five or six miles, and practically block the entrance to Indiana Harbor.

Q. Vessel men going to Gary or Indiana Harbor have to take what course?

A. Vessels bound for Gary still come by the way of South Chicago. There are no aids to navigation yet at the Gary harbor. They come to South Chicago, pick up the light station there and go due east about seven miles and then south into the harbor, in a roundabout course to escape these shoals.

Q. Do these conditions you describe here have anything to do with that?

A. Yes.

Q. What?

A. There is no navigable depth across these shoals. They are obliged to go around, with the present draft of boats.

Q. What other critical areas do you know anything about?

A. I might enumerate practically all of the harbors on Lake Michigan, though I have had nothing to do with some of them.

Q. I am speaking of your own observation. Go ahead, what is the fact with reference to the harbors of Lake Michigan, let us have in detail the facts about them?

A. Most of the harbors that I have had anything to do with are dredged to practically the present limits of navigation. Occasionally a boat goes in there with a specially low stage—

Q. When you speak of the present limits of navigation, what do you mean by that?

A. The present draft of the boats, that is, of the heavier laden boats.

Q. Well, now, take some of the harbors about which you know particularly?

A. The Milwaukee harbor, Racine.

Q. Tell us the facts about Milwaukee?

A. There are times when boats are obliged to wait for a rise in the stage to get across certain places that have shoaled to less depths than the general depth of the channel.

Q. That is to say, is Milwaukee harbor a harbor in which the depth of the water has anything to do with the size of boats that can come in?

A. All of the dredged harbors are affected by low stages of water.

Q. What other harbors are subject to that effect?

A. Racine Harbor and Green Bay, Sturgeon Bay canal. I suppose all of the harbors on the east shore. I am not familiar with them.

Q. I am asking you of the difficulties about which you know?

A. Cheboygan Harbor, Bay City.

Q. Do you know anything about the shoals in the straits off Cheboygan?

A. I made a survey of the shoals in the straits north and east of Cheboygan a year ago last summer.

Q. What is the fact about those, what did you find?

A. There are several shoals in that vicinity in which there are depths of 19 to 22 feet.

Q. Over what area?

A. They are small areas, several shoals.

Q. Does that have any effect upon the sailing course of vessels, if so, what?

A. The Lake Survey found it necessary to change the sailing courses on the Straits chart about a mile to the northward.

Q. Why?

A. To escape these shoals.

Q. Go on around, what other critical areas do you have knowledge of?

A. Alpena.

Q. What is the fact about that?

A. That is a dredged channel which is limited by the depth of dredging. The south end of Lake Huron is also shoal.

Q. Covering what area?

A. The channel from the head of St. Clair River for perhaps two or three miles northward.

Q. What harbors does that affect?

A. It is the south end of Lake Huron.

Q. Does that affect navigation to any points?

A. The entire navigation down the Detroit River passes through that channel. With a south wind, the boats drag the bottom there continually. The channel through the St. Clair—

Q. Is the navigation there limited by the depth of the water?

A. The navigation there is limited by the depth of the water at the present time.

Q. How deep is the water?

A. It is about 19 to 20 feet; depending considerably on the direction of the wind.

Q. What other critical areas have you investigated?

A. The channel through Lake St. Clair.

Q. What is the fact about that?

A. That is very little deeper than the present draft. There have been complaints of boats striking the bottom.

Q. Did you see anything of vessels dragging through the St. Clair?

A. I have followed boats through there when they stirred up the mud and sand from the bottom with their propellors.

Q. How many times?

A. I have a recollection of seeing that two or three times.

Q. Have you covered now the critical areas that you have investigated?

A. There is a large area at the west end of Lake Erie that is limited by the stage of water.

Q. How large?

A. Several miles from the mouth of the Detroit River out to deep water.

Q. What navigation does that affect?

A. Affects all the commerce on Lake Erie, commerce from upper ports.

Q. How deep is the water there?

A. It varies according to the stage of Lake Erie and the direction of the wind.

Q. Between what limits?

A. It would be between 19 and 21 feet.

Q. Over how extensive an area does that condition in the west end of Lake Erie affect navigation?

A. I am not prepared to say as to how large the area is.

Q. How many miles would you say? Vessels say coming down the river bound for Buffalo, how many miles—

A. Some three or four miles from the mouth of the river covers.

Q. That is, there is a space of three or four miles where that condition would affect the vessels?

A. From the mouth of the river.

Q. Have you investigated any other critical areas?

A. I should call the entrance to Green Bay through the Poverty Island passage a critical area.

Q. What do you know about that?

A. There is a varying depth of about 22 feet.

Q. Over what area?

A. It is just a short distance, perhaps a quarter to a half a mile.

Q. Is there any other critical area of which you have knowledge?

A. There is what might be called a critical area north of Thunder Bay Island.

Q. What is the fact about that?

A. There is quite an extensive area there with a prevailing depth of 26 feet and a minimum depth of 25.

Q. You say, "quite extensive." Can you define the limits a little more accurately?

A. The limits, within the five fathom curve is probably about sixteen to eighteen square miles.

Q. Vessels bound to what ports are affected by that condition there?

A. Practically all of the traffic from Lake Superior or Lake Michigan to Lake Erie passes over this area.

Q. You have had to do in your work with the Lake Survey with water gauge readings, have you?

A. I have had considerable to do with the reduction of the records.

Q. Have you had anything to do with the readings themselves?

A. I have inspected the gauges occasionally, and instructed the gauge tenders.

Q. I wish you would somewhat in detail describe these water gauges and tell us how the readings are made, and what part they play in these measurements?

A. The gauge that we use for our regular stations is an automatic self-registering gauge designed by Mr. Haskell, in which the stage of the water is shown on a continuous hydrograph. The gauge is run by clock work. The record is made on a continuous roll, generally for about a month's duration for each roll. The time is marked hourly by a separate device, and a stationary pencil on this gauge marks the datum plane. The records are derived from scaling between the datum plane and the stage line. The value of the datum is derived by a series of staff gauge readings and the scalings from the roll at the time the staff gauge readings are taken give the value of the datum plane. These staff gauges are referred to our standard bench marks. In reducing the records for purposes of getting daily and monthly means, we scale hourly readings, hourly ordinates. The mean of the twenty-four hourly ordinates constitutes the daily mean, and the mean of the daily means for the month gives the monthly mean.

Q. What do you know about the accuracy of these readings?

A. In what respect?

Q. Is there any checking up on that or verifying it?

A. A test of accuracy comes through a comparison of different gauges on the same lake or connnected lakes.

Q. What do you know about that now? Are you able to make any statements as to the accuracy of those readings?

A. We have gauges on Lakes Michigan and Huron which give a comparison in monthly means each month, and these

checked always, practically always, within a few hundredths of a foot.

Q. Between each other?

A. Between each other; sometimes there is a variation due to prevailing winds, but you can bank on the average.

Q. What does that agreement indicate with reference to the accuracy of the observations?

A. It indicates that any movement on one part of the lake is felt over the entire area of the lake.

In making our level adjustment for establishing datum, the water levels were used in connection with the precise levels, and were given the same weight as the line of precise instrumental levels.

Q. I think you said you had something to do with the computations determining the relation that exists between the stage of the lake and the outflow through the rivers?

A. Yes.

Q. What have you had to do as to those computations?

A. I have made up some of the computations, checked others, and have always studied the readings that have been sent in by the several assistants; am familiar with their work.

Q. You are familiar with the process used, are you?

A. Yes, sir.

Q. And with your practical work, and your knowledge of the subject as a basis, are you able to make any statement as to the relation that exists between the stages of Lakes Michigan and Huron and the outflow through the St. Clair River; if so, what is the fact?

A. I made a computation from the observations that were taken by other parties, and I derived an increment of outflow which is between twenty-one and twenty-two thousand cubic feet per second.

Q. What do you mean by increment of outflow?

A. Difference in outflow for a change of one foot stage on Lakes Michigan and Huron.

Q. Do you know anything about the relation that exists between the levels of Lakes Huron and Michigan and Erie, and Lake St. Clair?

A. The effect of a varying stage of Lake Erie on Lake St. Clair is about 44 per cent., and of Huron on Lake St. Clair about 37 per cent.

Q. What is the effect of the lowering of those lakes upon St. Clair?

A. They would have the same effect; the lowering of Lake

Huron would lower Lake St. Clair about 37 per cent. Lowering of Lake Erie would lower Lake St. Clair about 44 per cent. Those percentages are derived from the past gauge records that we have.

Q. You have gone all through those computations?

A. Yes, sir.

Q. You have had to do with them. You are speaking of work you have done yourself?

A. I have done that myself, yes, sir.

Q. If Lakes Michigan and Huron were lowered two inches, and Lake Erie two and a half inches, what would be the effect upon the level of Lake St. Clair?

A. It would be about an inch and three-quarters on Lake St. Clair.

Q. How do you determine that?

A. The effect on Lake St. Clair from the lowering of Lake Huron is about 37 per cent. I would give about three-quarters of an inch as the effect from the lowering on Lake Huron, and the lowering from Lake Erie would be about 44 per cent., of two and a half inches, or a trifle over one inch.

Q. You and the two together?

A. Add the two together.

Q. Which gives the total effect?

A. Total effect; would be an inch and three-fourths practically.

Q. You have come in contact, have you, Mr. Ray, with matters relating to navigation, in your connection with the Lake Survey?

A. Matters relating to what?

Q. Relating to navigation; that is to say, have you come in contact with matters relating to navigation to such an extent that you have any knowledge as to the effect of a lowering of two or three inches in the critical areas about which you have testified upon navigation?

A. I think I have.

Q. What would be that effect?

A. The effect of a lowering of two or three inches would be to lessen the draft of vessels by that much.

Q. Where would it have a practical effect?

A. It would have a practical effect on the load of vessels for passage through the critical rivers or into shoal harbors.

Q. Over the critical points and the critical areas about which you testified?

A. Yes.

Cross-Examination by Mr. Williams.

Q. In your opinion, Mr. Ray, would it be advisable to now proceed to deepen the lake at these critical points which you have testified about?

A. I did not catch the first part of your question.

Q. (The question was read to the witness.) In the interests of navigation?

A. I think it would be impracticable in some cases.

Q. Would it be necessary in order to serve the interests of navigation?

A. Any lowering of the waters of the lake would decrease the allowable draft of boats.

Q. You do not catch the purport of my question. I ask you whether or not in your judgment it would be in the interests of navigation to now proceed to dredge out and deepen the lake at these critical points that you have testified about?

A. It would be to the advantage of navigation to have some of these places dredged.

Q. Just indicate one of those places that you think it would be in the interests of navigation to dredge?

A. Lime Kiln Crossing.

Q. What is the depth of the water now at the Lime Kiln Crossing?

A. It varies with the stage. I think the limit now is about 21 feet.

Q. And in your opinion to what extent should that be deepened at that point?

A. I am not prepared to say as regards to that.

Q. Do you think it would be necessary to deepen it any? Would it be in the interest of navigation?

A. It would always be in the interest of navigation to have deeper channels.

Q. We are speaking now of this particular point, Lime Kiln Crossing.

A. (No response.)

Q. Are you familiar with the expense of deepening channels?

A. I am not.

Q. These critical areas that you have testified about, where the depth of water is from 23 to 25 feet, under what circumstances are those areas incapable of accommodating navigation, any navigation now taking place on the Great Lakes?

A. Vessels loaded to 20 feet would strike bottom and dam-

age themselves in considerably deeper water in a heavy sea; or during extreme low stages caused by prevailing winds. The rolling of the boat and the dragging down of the boat under headway also give a deeper draft.

Q. How many feet would you say that that rolling effect would be noticeable, or the diving effect.

A. I would not consider anything less than 30 feet would be safe depth, in a heavy sea.

Q. For a 20-foot draft vessel?

A. For the deep laden boats.

Q. That is if a vessel was loaded to a depth of 20 feet, you would consider it necessary to have a depth of 30 feet in order to protect that vessel in case of heavy sea?

A. That, of course, gives some margin of safety.

Q. Well, how much of a margin of safety is there in that ten feet?

A. I believe that a boat loaded to 20 feet would touch on 28 feet of water (mean stage) under the most adverse circumstances.

Q. How is that?

A. A boat would touch on something in the neighborhood of 28 feet, so they have reported.

Q. Then there would be, in your opinion, a margin of about two feet by providing for a 30 foot depth, a margin of safety of at least two feet and no more?

A. I don't think that is measurable precisely.

Q. In your opinion. You cannot testify to an accurate mathematical certainty, on a proposition of that kind, I assume?

A. I would not care to.

Re-direct Examination by Mr. Wilkerson.

Q. Coming back to those shoals again, and the relation of shallow water there to practical navigation of the lakes, is there any kind of weather which might have some effect on navigation, even though there were a channel around, if they went into South Chicago and went around that way?

A. It is very often the practice of masters to hug the lee shore to protect themselves from the heavy seas out in the open lake, and some of these critical areas are along the shores.

Q. You cannot always follow the channel around the shoals in thick weather, can you?

A. You cannot.

Q. Do you know anything about the improvements which are proposed and under way, which will make these critical points about which you have testified more important with reference to navigation?

A. I suppose the construction of the Livingston channel and the new lock at the Sault will have an effect of deepening the draft of boats.

Q. What would be the relation of that situation to these critical areas about which you have testified?

A. That will make depths of between 20 and 30 feet more critical than for shoaler draft boats.

Mr. Wilkerson: That is all.

Recess to May 26, 1909, at the hour of 9:30 o'clock a. m.

F. C. SHENEHON, a witness called on behalf of the Government, was first duly cautioned and sworn and testified as follows:

Direct Examination by Mr. Wilkerson.

Q. What is your name?

A. F. C. Shenehon.

Q. Where do you live?

A. Detroit.

Q. What is your occupation?

A. Civil engineer.

Q. What position do you hold at present?

A. I am principal civilian engineer of the United States Lake Survey.

Q. Stationed where?

A. At Detroit.

Q. What has been your education as an engineer, college education?

A. I attended the University of Minnesota, and hold two degrees, Bachelor of Civil Engineering and Civil Engineer.

Q. What has been the nature of your work since you commenced the active practice of your profession?

A. I was on railroad location and construction between 1886 and 1888. In 1888, I opened an office at Sault Ste. Marie and was in general practice as a civil engineer; and in 1891 I entered the service of the Engineer Department of the Government in the construction of the Poe lock at Sault Ste.

Marie. I was at Sault Ste. Marie engaged on work connected with the building of the lock and the channellization of St. Mary's River up to 1898. The work there included also discharge measurements, on St. Mary's River made in 1896, and reduction of measurements and discussion of hydraulic measurements at that time.

Q. What next?

A. In 1898, July, 1898, I was transferred to Buffalo as engineer for the Board of Engineers on Deep Waterways, in the discharge measurements of the Niagara River; and for two months had charge of the office in that work. That included slope measurements on the river, and discharge measurements at the International Bridge. The Lake Survey then took up the work, and I had charge of the office at Buffalo up to August, 1900. During that period we were engaged in making discharge measurements and the reduction of the same. In August of 1898, I was transferred to the St. Lawrence, and made discharge measurements of the St. Lawrence River during the fall of 1900 and the spring of 1901. Then I was engaged on surveys, a resurvey of the St. Lawrence River for the balance of that year.

I should have stated that during the winter of 1901, I made discharge measurements of the upper St. Lawrence River through the ice, in corroboration of the measurements at Point Three Points. During 1902 I was engaged in surveys on the St. Lawrence River. In 1903, 1904 and 1905 I was in charge of surveys on the lakes, mainly Lake Erie, using the steamer General Williams. In connection with that work, I was afloat making surveys, and became acquainted with lake conditions. In 1906, I was engaged in work on the Niagara River in connection with the Preservation of Niagara Falls, hydraulic work; and during that season I was ordered to the Detroit office to relieve Mr. E. E. Haskell, Principal Assistant Engineer of the Lake Survey, Mr. Haskell going to Cornell University as Dean of the School of Civil Engineering. Since that time I have acted as principal Civilian Engineer of the Lake Survey.

Q. You have spoken, as part of your work and experience, of having had to do with the making of discharge measurements. What do you mean by that? What is the purpose of such measurements? You referred to the Niagara River, the St. Lawrence and the St. Clair River in that connection?

A. The object of the discharge measurements is to establish a relation between the elevation of the lake surface and

the river outflow. That is, for a particular elevation of the lake surface in the vicinity of the head of the Niagara River, for instance, there is a certain volume of outflow, perhaps 200,000 cubic feet per second. Now, when the lake rises a foot, the outflow is increased for two reasons, namely: because the water is deeper in the river, and because also it is flowing with a somewhat higher velocity. And when the lake at the head of Niagara River has gone up a foot, the discharge might be 222,000 cubic feet per second instead of the 200,000 cubic feet at the foot lower level. A long series of observations, or a series of observations in which the stage of the lake is at different elevations, allows us to state a relation between the elevation of the lake surface and the quantity of water flowing out of the river.

Q. You have given some consideration, have you not, Mr. Shenehon, to the question which is presented in this case, namely, the extent of the lowering of the Great Lakes system due to a diversion of the water from the lake at Chicago?

A. I have given very considerable attention to it.

Q. You have gone over the questions that are involved, and have made a special study of them, have you not?

A. Yes.

Q. With a view to reaching a conclusion on that subject?

A. Yes.

Q. Now let me put rather a general question to you first, before we go into those matters that relate to the determination of the exact extent of the lowering. As a result of your observations and study, which you have given to these questions, what have you to say as to the effect of the diversion of the water from Lake Michigan at Chicago upon the elevation of Lakes Huron and Michigan; and state your reasons for it?

A. It is certain to be followed by a lowering of Lakes Michigan and Huron.

Q. Why do you say that, independent of any obesrvations or computation as to the extent of the lowering; I mean the general principles that apply there that lead you to make that as an absolute statement?

A. The level of the lake is determined by the amount of water presented for discharge in its outlets, and the natural outlet (in the case of Lakes Michigan and Huron, the St. Clair River), at a given lake elevation, can do a certain amount of work in disposing of that surplus water. Now, if the work of the St. Clair River is assisted by an independent, or a new canal, as at Chicago, the amount of water to be disposed of by

the St. Clair River is lessened, and the lake will drop to a point where the sum total of the outflow in the St. Clair River and the drainage canal equals what it would be in the St. Clair River, at a higher lake elevation under the earlier conditions.

Q. A moment ago you made some reference to velocity, in connection with the depth of the lake. Will you state again and a little more in detail just what that relation is. I think you said the more water there was in the lake, the higher the lake was, the faster the water would flow?

A. It is flowing under a higher head.

Q. Is that the result of the application of natural laws?

A. It is a general principle that the speed of water bears some relation to its head, other things being equal.

Q. Now you have spoken of the lowering of the lakes as the result of the diversion of water at Chicago. With what meaning do you use the word "lowering"?

A. Lowering is referred to the lake surface which would have prevailed in the absence of the diversion; that is, the lake may actually rise, while this lowering is going on at the same time, in just the same way that a man who is on a railroad train traveling *east* may reach the tail end of the car he is in by walking *westward*. It is a case of two movements going on at the same time. This lowering is going on, and it is independent of the other fluctuations that may prevail at the same time.

Q. What is the relation between the lowering caused by the diversion of this water at Chicago and the outflow in the St Clair River?

A. I do not know that I understand the question.

Q. (The question was read to the witness.)

A. The level of Lakes Michigan and Huron would fall until the lake at a lessor stage is discharging in the two outlets what is discharged in the St. Clair River alone under the normal condition of lake level.

Q. In connection with the waters of the Great Lakes, you make use of the term "net supply." With what meaning is that term used?

A. Over a long term of years it is the amount of water discharged from the lake through its outlet.

Q. Now what are the elements that enter into the determination of this net supply?

A. In the case of Lakes Michigan and Huron, the water brought in by the St. Mary's River, and the rainfall upon the lake's surface itself, the rainfall upon its drainage area or

water shed, less the evaporation which takes place from the water surface and from this water shed.

Q. You speak of evaporation, rainfall, etc., as being elements in determining the quantity of water there is in the lakes to be disposed of. Those are variable elements, I assume; that is, they change from time to time?

A. Yes.

Q. Now what relation exists between those and this element of the diversion of the water at Chicago?

A. Why, the diversion is independent of it. It makes no change in these elements, evaporation, rainfall.

Q. That is to say that remains a fixed factor?

A. Yes.

Q. Which modifies what would be the resultant of the others, whatever that might be?

A. Yes.

Q. I think you have already stated that you have made considerable study and have done considerable work in investigating the outflow through the St. Clair River, did you, Mr. Shenehon?

A. I have done some work in investigating the St. Clair River.

Q. And in connection with the matter that we now have under consideration here, you caused to be made certain plates showing the result of the observations, did you?

A. Yes.

Q. Now I wish you would take up those plates. They have already been marked here for identification as "Complainant's Exhibits 1, 2, 3 and 4," respectively. Starting in with No. 1, will you state what the purpose of preparing that was, how it was prepared and what you had to do with the platting of those observations; what you know with reference to the correctness of the platting, and what the conclusion reached from the observations which are there platted is, with reference to the relation between the elevation of the lake and the discharge of the St. Clair River?

A. On this plat, the elevations of Lake Huron at Harbor Beach are platted in the vertical.

Q. These observations with reference to the stage of the lake were made from the records here in the office?

A. From the records of the United States Lake Survey.

Q. And the others, the observations as to the outflow, where did you get those figures?

A. From the measurements of the St. Clair River as derived from the records of the United States Lake Survey.

Q. Are those records here in Detroit, are they kept here?

A. Yes.

Q. In permanent form?

A. Yes.

Q. You have the names of the men who made the observations in each case, have you?

A. Yes.

Q. And that is a matter of record here?

A. Yes.

Q. What do you know as to whether or not the observations both as to lake elevation and as to the outflow through the river were correctly put down on the plate?

A. I have checked the platting of that, and know that they are correctly platted.

Q. The platting then is a correct representation of those observations as they appear from the records of the Lake Survey?

A. Yes.

Mr. Wilkerson: Are you gentlemen ready at this time to decide this question: whether this plat may be considered precisely as if the witnesses who made the observations were produced and testified; that these observations were made in the way in which it has already been testified in the case as to observations with reference to the determination of the stage of the lake and the outflow; and that if each one of the witnesses who had to do with the making of these observations were put on the stand, he would testify that he made the particular observation, and that it is correctly put down in the records of the office. What I desire to obviate is the necessity of producing what you would call the best evidence with reference to the observations, and to give to the records of the Lake Survey the same effect that would be given to the testimony of the witness, if he was on the stand and said that he made that observation.

Mr. Williams: We will accept the records of field work, as filed and reduced in this department, as being competent evidence, subject to an inquiry as to the probable limits of error of the original observations.

Mr. Wilkerson: Subject to the right on your part to inquire into probable error of individual observations.

Mr. Williams: Yes. Of course, I would say this, I do not know that we are prepared to admit the correctness of all the

methods of reduction. In using the word reduction of observations, I mean to include simply the determination of the actual elevation of a station, for instance, or the determination of the quantity of discharge in an individual observation. We would not want to admit the correctness of these methods in themselves. We will admit the correctness of the data on which they are based.

Mr. Wilkerson: That is the point. The agreement is that the records of the Lake Survey may be treated as of the same effect as the testimony of the witnesses who made the observations; and it is not necessary to produce, and introduce in the record in this case all of those records, but that the witness may say they are correctly represented on the chart. You have then, of course, the right if you want to, to take those observations and to recheck them to see whether or not they have been in fact correctly platted.

Mr. Williams: They would be as open to us as though the man was testifying.

Mr. Wilkerson: Yes. Now, we have Mr. Shenehon's statement that they are correctly put down. You have the unquestioned right to check that if you wish and to show that the platting is inaccurate in any respect, or that you reach different results from the ones he has reached. In other words we get the observations as the foundation.

Mr. Williams: Yes, the original data we accept.

Mr. Wilkerson: Each side can go ahead with its own method.

Q. Starting out now with the foundation that you have on this plat "Complainant's Exhibit No. 1" a correct graphic representation of the observations as they appear from the records of the Lake Survey, will you now go ahead with your description of the plat?

A. The elevation of Lake Huron at Harbor Beach is platted for a discharge observation in the vertical, and the volume of river flow is platted in the horizontal scale, increasing from the left hand towards the right. Using these two scales as a system of rectangular coordinates, an observation which here consists of a group of ten actual discharge observations, except as specifically stated on the plate itself, is platted in the vertical at its proper elevation of Lake Huron, and in the horizontal with the corresponding volume of outflow in cubic feet per second. After the observations thus grouped are platted, a straight line is drawn threading these observations, and this straight line is taken to indicate the

relation between lake elevation and volume of outflow. The exceptions to the groups having ten observations in each are: U has four, Y six, Z eight and Alpha seven. The total number of discharge measurements is indicated at 255. A note appears on this plate that observations of 1901 were adjusted for abnormal stage of Lake St. Clair. Those observations were not taken into account in drawing the line or deriving the increment. They are platted simply to show where they do fall when adjusted for the abnormal stage of Lake St. Clair.

Q. Why were those disregarded, Mr. Shenehon?

A. During the winter and spring of 1901, St. Clair River was blocked with ice, and Lake St. Clair showed an abnormally low stage.

Q. Was that an extremely extraordinary condition, the one that was prevalent that year?

A. Yes. I do not know another instance where Lake St. Clair was as low and held as low in its relation to Lake Huron, as that particular spring.

Q. Was the discrepancy a wide one?

A. They were rejected and treated in this way, because they do not represent normal conditions between Lake Huron and Lake St. Clair. The attempt to get the law of discharge is to get it for normal conditions and the use of these observations of 1901 would have falsified, rather than made the truth clearer.

Q. Having drawn that line representing the law of discharge, you derived what we refer to in this matter as the increment. How do you determine that after you plat the observations?

A. This diagonal line passes between two horizontal lines a foot apart in lake elevation, as between 580 and 581, and dropping a vertical line from the point of intersection with the upper horizontal until it intersects the lower, the base of the triangle formed is the increment. An increment simply means the rate of change of outflow for a change of a foot in elevation in lake surface. That description is perhaps rather involved, because the increment is an exceedingly simple thing. It bears the same relation in a discussion of this kind that interest does in financial discussions. It is the rate. It is the rate of change of outflow for a foot change in the lake level. If we had taken two observations, one of them being at 581 and another one at 580, and these observations

were absolutely correct, the difference between those would be the increment.

Q. The increment as derived from those particular observations is correctly stated on that plat is it?

A. Within such limits as I will state later in my evidence.

Q. Now I understand that the data relating to those observations have been placed in the hands of counsel on the other side?

A. Yes.

Q. For the purpose of going over them and making any question they desire with reference to the accuracy of the plat as shown?

A. Yes.

Mr. Wilkerson: It is understood that we need not put those figures in the record, is it not, Mr. Williams, unless you wish to have them in by reason of something which you may wish to question as to the accuracy of the plat as drawn?

Mr. Williams: I think we would like to have this material here bearing upon the summary of discharges of the Niagara River and of the St. Clair River, testified to as being correct transcripts from the original field data.

Mr. Wilkerson: Q. With reference to these original observations, just what data have you furnished the counsel on the other side, so that we may have it here in the record?

A. For the St. Clair River, tables marked: U. S. Lake Survey, discharge measurements, Dry Dock Section, St. Clair River 1899, 1900, 1902; Tables 1, 2, 3, 4, and 5. With the same heading, Table A, the measurements of 1901 showing the adjustment made for abnormal stage of Lake St. Clair, Table not indicated by letter or number, with the same heading, for the year 1908. A table marked: U. S. Lake Survey; hydraulics of St. Clair River; summary of discharge measurements, Section Gorge, Sherman Moore, Jr., engineer, April, 1909; marked Table 5. Table No. 2, summary of discharges, Open Section, Niagara River, F. C. Shenehon, U. S. Assistant Engineer 1906. Table No. 2, same heading. Table No. 1, summary of discharges International Bridge Section Niagara River, F. C. Shenehon, U. S. Assistant Engineer 1906. Continuation of the same table showing measurements, Number 5 to 68, inclusive. Continuation of the same table showing the measurements 69 to 124, inclusive, with such exceptions in the inclusion as noted on the last sheet. U. S. Lake Survey, Preservation of Niagara Falls, elevation of Lake Erie derived from discharge of Niagara River, Inter-

national Bridge, Buffalo, New York. Table 47 in three parts. These are the observations of 1907 and '8. Table No. 1, summary of discharges, Three Point Section St. Lawrence River, F. C. Shenehon, Assistant Engineer May, 1906, in two parts, including observations 1 to 96, inclusive.

Q. These tables show the facts with reference to the original observations upon which these plats are based?

A. Yes. A reservation should be made in making that statement for the St. Clair particularly of certain transfers of water level which are included in the reduction of the observations as for instance between Fort Gratiot, and Harbor Beach.

Q. Just explain that?

A. Where two water gauges are a short distance apart (and when I say short, that may mean as much as one hundred miles) the elevation of one may be derived from known elevations of the other; and the accuracy with which this may be done is so great that it is given the same belief as the best precise levels. In other words, the water surface is a great leveling instrument itself, and two water gauges and the water surface form a leveling instrument, so we can pass from one gauge to the other. This is true also of the equivalent relation between the lake water gauge and the river surface; and some changes have been made in elevations between the G. T. R. Gage near lead of river and Harbor Beach, in reducing these observations. The error in such a case is small. There may be an error as much as one-tenth in the transfers from Dry Dock section to Harbor Beach, one-tenth of a foot. The fall between Harbor Beach and G. T. R. Gage, as I recollect it is 77/100 of a foot; that is the normal ordinary fall.

Q. Now with reference to your checking up of these tables, as has been already indicated, is there any other explanation that you would like to make?

A. No.

Mr. Wilkerson: That covers everything that you wish to know, for the purpose of going over them. The question of actually incorporating these in the record, we will reserve until you gentlemen have the opportunity to go through them more in detail?

Mr. Williams: Yes. You can say now on the record, I think, that there will be no objection made to the admission of these tables, on the ground of their not being the best evidence, by either side.

Mr. Wilkerson: These tables will be taken as if supported by the testimony of the witnesses who made the observations?

Mr. Williams: That is it.

Mr. Wilkerson: And their correctness will be assumed.

Mr. Williams: That is that they are a correct representation of the work of those witnesses.

Mr. Wilkerson: With the additions and explanations that Mr. Shenehon has made as to one or two points here.

Mr. Williams: Yes.

Mr. Wilkerson: Of course it would be unnecessary for us to put them in the record, and it would only encumber the record unless there is some matter concerning which you wish to question the accuracy of our charts, because the way the record stands now we have that summarized on the plat, so that they become immaterial.

Mr. Williams: Unless we want to introduce them.

Mr. Wilkerson: Unless you want to put them in for some reason. I think now there is no question about either the plats that have been already identified or this data, as to its availability for use by either side as the best evidence in the case.

Mr. Williams: That is all that part of the plat which refers to this data. We are going to object to those parts of the plat which contain those scales, as conclusions. We are going to object to this part of the plat on the left side; in the first place, on the ground it assumes to show the difference between a situation with no diversion at Chicago and a situation where there would be 14,000 cubic feet diversion. That is not the issue in this suit. There is only 4,000 cubic feet involved in this suit. All of this we will object to going into evidence at all.

Mr. Wilkerson: I will put a question to the witness about that scale at the side. (Q.) You had that prepared, did you?

A. Yes.

Q. It correctly represents the result of the plat, does it?

A. It represents two parallel scales in which one corresponds with the horizontal side of the triangle referred to before, and the other the vertical side. It reduces to a scale of inches the relation between change of lake surface elevation and change of outflow. It permits the application of the rate of outflow, or increment, to a particular diversion, as 4,000 cubic feet per second, graphically and readily. And its purpose is none other than to make that process easy, and clear.

Q. Is there anything else now with reference to this Exhibit No. 1, in connection with its preparation, or in explanation of it, that you have to add to what you have said already, Mr. Shenehon?

A. The note on the plat states the discharge observations of 1899, 1900 and 1902 are shown by circles; the observations of 1901 are shown by triangles and those of 1908 by squares. The object of this is to distinguish them. The number of observations for each year: 1899, there were 90 measurements of the river flow; 1900, 66 measurements of the river flow; 1901, 36 measurements; 1902, 48 measurements; 1908, 15. This is on the Dry Dock section. In 1908, 22 additional observations were made on a new section not shown on this chart. This shows 219 measurements of the river flow made under conditions approaching normal. I say approaching normal because individual observations might have shown some tilt up of the lake, Lake Huron, to which St. Clair did not immediately respond; but part of these would be where the lake was a little high, and probably an equal number would be where Lake Huron was on the low side. The errors that may come from this are compensating, and the grouping of the observations as has been done would serve to eliminate or offset any error that might be introduced from this cause.

Q. Exhibits 2, 3 and 4 were also prepared under your direction?

A. Yes.

Q. What you have said with reference to the correctness of the observations as represented on Complainant's Exhibit No. 1 relating to the St. Clair is applicable to each of these other plats is it?

A. Yes, with such explanations as the plates themselves bear regarding the number of observations and the grouping.

Q. Let us take up No. 2: Is there anything in connection with No. 2 that you should add by way of explanation?

A. In the case of the discharge of the St. Lawrence, this represents the discharge as it was taken in 1901, 1902, and the relation between elevation of water surface and volume of discharge is for the water surface of the St. Lawrence River at Ogdensburg. The movements of the water surface at Ogdensburg are about two per cent different from those of Lake Ontario itself; that is when the water goes up a foot at Ogdensburg, it will go up a foot and two hundredths in Lake Ontario. A further reservation of statement should be

made regarding this chart that in 1903 one of the outflow channels at the Galops Rapids was dammed by the Canadian Government and the increment of discharge was lessened by that damming. The change in the discharge was 5½ per cent, and it is assumed that for a given stage of the river at Ogdensburg, the discharge after the Gut dam was put in place (and it was put in place in 1903) was 5½ per cent less than it was before. It is assumed that the increment has changed in the same ratio; that where the increment is shown as 28,870 here, it should be lessened 5½ per cent.

While touching on that point, it might be well to state that the 1908 observations on the St. Lawrence River verified the value of the 5½ per cent change within, I think, a half of one per cent. That loss of discharge by reason of the Gut dam was most accurately deduced by water gauge readings in the lower river at the Rapide Plat. The water gauge is read daily and has been for a great many years, and the discharge observations calibrate the weir. The same condition holds at the head of the Long Sault Rapids above Cornwall. There the Canadian authorities read the water gauge daily at noon, and that weir was also calibrated, so that when the Gut dam was put in place by the loss in level on these particular weirs, we knew very exactly what loss of discharge was occasioned by the building of this dam. So it is not an estimate; it is an accurately derived statement; and the corroboration of the 1908 observations is confirmatory of that.

Q. Those are the observations with reference to which Mr. Moore testified on yesterday?

A. Yes.

Q. Is there anything further you want to state with reference to that?

A. I might state that the total number of discharge observations is 93 in that 1901-1902 work.

Q. Is there anything further with reference to No. 2 or with reference to Numbers 3 and 4 that you wish to add by way of explanation?

A. No. 3 and 4 need no explanation, except as the explanations are contained on the sheets themselves. I might state here that the number of discharge observations in 1898 to 1900 at the International Bridge were 101, and in 1907 and '8 there were 118 that were utilized on this chart. Subsequent to this eight more observations were taken last fall, which are not incorporated. That makes a total of 219 observations utilized in this chart. In the case of the Open Section on the

Niagara River, the total number of discharge observations is 121.

Mr. Wilkerson: I think I made my statement broad enough about these original observations to cover all the plats.

Mr. Williams: Yes. It may be understood that what was said at the time of the discussion concerning Plat No. 1 applies to all these plats.

The Witness: Seventeen observations made in 1898 by the Deep Waterways Commission were utilized to this extent.

Q. Observations made where?

A. At the International Bridge, on the Niagara River. They were made under my direction, incidentally. The velocities at the different stations, the twenty-one different stations across the river were used, but in reducing them the coefficients and cross sectional areas, as deduced later and more accurately by the Lake Survey, were used, but to the extent of taking the velocity, the data is Deep Waterways data.

Mr. Williams: Q. That is they were used by applying to them the sections which you had later more accurately done?

A. Yes. It might be well to add that in this work the United States was in a measure collaborating with the Deep Waterways, as they were in the precise levels run on the St. Lawrence.

Mr. Wilkerson: Q. Now, Mr. Shenehon, what do you say as to the extent of the lowering of Lakes Huron and Michigan as a result of the diversion of 4,000 cubic feet of water per second at Chicago, and on what do you base your answer?

A. The lowering would be between two and two and a half inches in my opinion.

Q. And would that answer apply proportionately to the diversions of other quantities up to say fourteen or fifteen thousand cubic feet per second?

A. Yes.

Q. On what do you base that answer?

A. The observations made by the Lake Survey, the discharge observations, with a possible error in the increment of 25 per cent. The observations as platted indicate a lowering of two inches, and in my belief that is the least lowering that is probable.

Q. Why do you say that is the least lowering that is probable?

A. I base that on the fact that Sabin's earlier measurements indicated an increment of about 19,000 and the measurements made at the Gorge section during 1908 by Mr. Moore

indicate an increment in the neighborhood of 20,000. I base it further on the fact that the physical conditions in the St. Clair river are such as to indicate a fairly small increment. That is, a river that is narrow and gorged, and has to get its cross sectional area by depth in large part is more likely to have a small increment, than one with a broad outlet. That point is well illustrated in the Niagara River, where the upper river is considerably narrower than the river at the head of the Rapids at Niagara Falls. The broad river, something like three-quarters of a mile at Niagara Falls, with not much over a quarter of a mile at Buffalo, makes the increment about half at Niagara Falls of what it is at Buffalo, in the upper river. And we have a further illustration of that when we go down to Suspension Bridge and the Whirlpool. There the increment is somewhere in the neighborhood of 9,000, less than 9,000, and the reason for the small increment there is the narrowness of the river about 400 feet; the river is gorged. And the same is true of Suspension Bridge. A fairly similar condition exists at the head of the St. Clair River, at what is known as the gorge there; it has a width of about 800 feet. It has a depth of over 60 feet with a width of about 800 feet.

Another reason why I think the increment is likely to be smaller than 24,000 rather than larger than 24,000 is the certain relations holding between Lake Erie and Lake Huron. The movements of Lake Huron are larger than those of Lake Erie, which would indicate that the increment is smaller. Perhaps those are not very definite reasons for my belief that the increment is smaller than 24,000, but it has influenced my judgment and I believe it to be true.

Q. What would be the effect of the lowering of the level of Lakes Michigan and Huron upon the St. Marys River?

A. Well, the lowering at any point on Lake Michigan would be accompanied by a similar lowering throughout the whole of Lakes Michigan and Huron, and in all harbors and bays, and would extend up St. Mary's River with some small diminution; I should say it would reach the locks with a loss of 20 per cent. That is 80 per cent of the effect shown on Lake Michigan would be indicated in the floor of the Poe lock, or over the floor of the Poe lock.

Q. What is your reason for saying that 80 per cent of that effect would be found there?

A. That is an estimate, and is based in some measure on back water effects in the Detroit River and the St. Clair River,

and in the Niagara River as well. The fall from the level of the water at the locks to Lake Huron is not much over a foot at the present time, and with a deep stream with no rapids, the back water effect, the largest percentage of it would go up. Speaking rather roundly, if 60 per cent of the effect would travel up the Detroit River from Lake Erie to Lake St. Clair, or 66⅔ as the Deep Waterways estimate it, that is up a rise of 3½ feet, it seems very reasonable that 80 per cent would go up the St. Marys River, and if 50 per cent of the effects of a rise on Lake St. Clair would be transmitted to Lakes Huron and Michigan, that is up a rise of about 5 feet the 80 per cent for St. Marys River seems a very safe estimate. Under present conditions, it has not been computed; we have not observations enough. The taking away of the cofferdam in west Neebish has lowered the water at the Sault locks and brought in a new condition of back water effect, and 80 per cent I think is a conservative statement.

Q. Would the effect of a diversion of water at Chicago upon the elevation of the lakes manifest itself immediately?

A. No, it would take some months.

Q. How long would it take for it to assert itself?

A. Taking an increment for the St. Clair River of 23,820 or 24,000 speaking of it roundly, it would take about four years. If the increment were half that, it would only take two years. It varies directly as the increment.

Q. That is to accomplish how much of the total effect?

A. That would be nine-tenths.

Q. It would accomplish nine-tenths of it in about four years?

A. Yes. To get the other tenth would take just as long.

Q. You said you had to do with the measuring of discharges in the Niagara River?

A. Yes, I was in charge of the Buffalo office from July, 1898, until August, 1900.

Q. Give us some information with reference to the detail of measuring those discharges, and also with reference to the extent of the measurements?

A. The first section of the river measured was that under the lower chord of the International Bridge. The International Bridge crosses the river at what is known as Black Rock and consists of nine spans, and these spans were divided up so that each river width of about 80 feet was considered as a small stream by itself. The first three spans were divided into two stations each, and the spans four, five and

six (I am counting from the American side) had three stations, and spans seven and eight, two each, and span nine, one. There was very little flow in the ninth span; the water was very shallow and small current. The elevation of the water surface was determined by water gauges, one on each side of the river. These gauges were of the box and bottle type which accurately give the water surface to 1/100 of a foot. Later on a self registering water gauge was put in the slip at the foot of Austin street, which is about 3/10 lower down the river; that is 3/10 in elevation. The river was sounded at very frequent intervals, I believe as often as ten feet, very accurately sounded to get the cross sectional area, in conjunction with the water surface elevation.

In sounding, the water surface itself was used as the plane from which measurements were made. By that I mean to say that we did not take the plane of the water surface as indicated by the water gauge but the measurement of depth was between the water surface and the bottom, in each position. I state this because the possible curvature of the water surface is eliminated by doing that. The sounding was done with a 140-pound cast iron weight which was of a projectile shape. It was drawn out sharp at the nose and it was slotted at the stern and a tail put in it so that when it was in the current it was held nose-on, with very little current resistance. It was let down by $\frac{1}{8}$ of an inch wire from a reel; the reel having a circumference of exactly five feet. In order to insure the accuracy of the indications of the reel, it was tested before the soundings and built up, so that exactly 20 feet of the wire made four turns of the reel. Under the influence of current pressures the weight sagged down stream a short distance, and to compensate this it was hauled up above the water surface by guys, and a small correction was applied for the inclination of the submerged wire. In 50 feet of water this correction would not exceed, and I think in all cases was less than a half a foot. That is with water running five miles an hour and 50 feet deep, that was the condition. In most of the spans the depth is less and the current is less swift, and the correction amounted to only perhaps 2/10 of a foot.

After getting the cross sectional area by water gauges and soundings, a meter is let down at 3/10 depth, about midway of each of the stations, one at a time, and a second meter was made to traverse every tenth of depth over a number of sections throughout the station, as often as 20 feet in the

width of the river, each 20 feet, and in many cases, as when approaching the piers, more frequently; and the velocity relations were established between this traveling meter and the one that was stationary at the station or at the three-tenths depths of the station, which we call the index. These observations were made in great detail and over considerable periods, and in the end we derive the volume of the water passing per second, when the velocity indicated at the index is multiplied by the cross sectional area, and reduced by a coefficient which is determined by these velocity relations. After the work I have been speaking of, coefficient work, after that has been completed, a discharge measurement consists of taking a velocity measurement, or two velocity measurements as a rule of two minutes length each, on each station, each of the twenty-one stations of the Bridge Section. At the same time a self registering water gauge located in the lake above the head of the river indicates with a precision of one to two one hundredths of a foot the lake elevation at the time. The volume of outflow, as indicated by the current meters and the section gauge, is then determined with respect to the elevation of the lake as shown by the self registering gauge.

Q. Are those observations that you made in the Niagara River embodied in any one of the plates that are in this record?

A. Exhibit 3, International Bridge section.

Q. Those observations were made under your directions, and many of them by yourself?

A. Yes; personally in part and under my direction all of it.

Q. So that you had the opportunity to know very definitely with reference to the care with which they were made and as to their accuracy?

A. Yes, I made the program, and in some part the methods employed, and personally saw to it that every check that would insure the highest accuracy was used.

Q. I think you mentioned some other measurements of outflow you had to do with personally?

A. Yes. After completing the measurements at the bridge section, in order to verify the relations found there, a new section was established in the open river about 1,800 feet below the International Bridge. This is known as the Open Section. In that section there were seventeen stations, each one of a hundred feet in width. When I say "station" I am using it in two senses. The one hundred foot width of the river,

we sometimes speak of as a panel and sometimes as a station; and the point where we observe, the vertical line midway of the panel is spoken of also as the station; but in the Open Section we observed at the four-tenths depth at station in making discharge measurements.

On the Open Section we had water gauges at each end of the section, that is on each side of the river, and when I say on each side of the river I mean the Island side, that is the American side (there is an island coming in there), and the Canadian side. These gauges were constructed so that we could read from the instrument boat, the Catamaran, the elevation of the water surface to 1/100 of a foot, at any time. And as we made our observation for velocity we also read the gauge, one or both. The soundings were made on that section every ten feet by the same methods as indicated for the bridge section except that we needed no guying as we were close to the water. On that section 121 measurements of the flow were made, and are incorporated in Exhibit No. 4.

Q. What was the result of those measurements, so far as the increment was concerned? Was this second set of observations made for the purpose of checking the prior ones?

A. Yes, to verify the prior observations.

Q. What was the result?

A. The volume of outflow checks within 1.3 per cent that of the International Bridge.

Q. What does that indicate to you as an engineer with reference to the correctness of this work, the obtaining of that result?

A. It indicates correctness, that the work is correct.

Q. You have given us your statement with reference to the effect of the diversion of water at Chicago upon the elevation of Lakes Michigan and Huron. What would be the effect upon Lake Erie?

A. That is of 4,000 cubic feet?

Q. Yes.

A. Lake Erie would be lowered. All of the Great Lakes below Superior, below the foot of the locks in St. Marys River would be lowered.

Q. Speaking of the amount of water which it is proposed to divert at Chicago, I take 4,000 because that is the figure charged in the bill, and I assume when you make a statement with reference to 4,000, the statement which you make would apply proportionately to other quantities?

A. Yes.

Q. Within a limit of up to 14,000 cubic feet per second, I will say?

A. Yes.

Q. So it will not be necessary to speak of the effect with reference to all these different quantities, but when you speak of it with respect to 4,000, you will be understood as having your answer apply proportionately to other quantities. Is that correct?

A. Yes, that is correct.

Q. To what extent would Lake Erie be lowered, and upon what do you base your answer? Before you answer that, Mr. Shenehon, going back to the Niagara River, did you take the increment of the Niagara River also, as you did the outflow, those two sets of observations about which you testified?

A. Yes.

Q. How did that check?

A. The increment as indicated by the Open Section is 21,640 and the increment as shown by the International Bridge section is 21,900.

Q. Does that indicate the same thing to you as an engineer as to the correctness of this work, the fact of that agreement?

A. Yes.

Q. Now as to Lake Erie again?

A. I think while we are on increments I would like to say a little something.

Q. All right, if there is any further explanation of that, you may make it now before we take up the effect on Lake Erie?

A. In a report made by me in 1906, I make the increment at mean lake level, 21,720.

Q. What river are you now speaking about?

A. I am speaking of the Niagara River; that is by the Open Section, 21,720.

Q. To whom was that report made?

A. That was made to Colonel Luck, officer in charge of the Lake Survey.

Q. Is it published?

A. No, unpublished. It became eventually a part of the report to the Chief of Engineers for that year, but was not published.

Q. It is referred to in that report?

A. Not in the printed report. The policy of the govern-

ment is not to print technical publications at the present time.

The International Bridge section shows an increment of about 22,000. In these reports, the law of discharge was not taken as an exactly straight line, but the discharge was taken to vary as the 3/2 power of a certain depth at the head of the river. For the Open Section the increment between Lake Erie elevations 569 and 570 is about 19,290 and between elevations 574 and 575 is 23,210. In the plats Exhibits 3 and 4, the discharge line is given as a straight line, and the error of taking it as a straight line is insubstantial, so far as the matters in this case go.

Q. That is by that you mean that there is no substantial difference in the result obtained when you draw the straight line as it is in the plates which have been offered in evidence and when you draw it as a slight curve as drawn in the other computation?

A. As regards the effect on the lake level, I should say whether you take a straight or curved line, whether you use the increments as shown in my 1906 report or whether you use those shown on the plates, the effect on the level would not vary one-sixteenth of an inch; that is taking the lake in the four or five years in which it may be lowered. If you consider the lake at a pretty high stage, then the lake would be tending to lower at a lesser rate, but when the lake is lower, it is tending to lower at a greater rate, and the lowering at mean lake level is the thing that counts.

Q. As I understand one of your last statements—I want to be sure that I am correct in it and if I am not, correct me—you start out with these observations which are put down on these plates. There are two different methods of determining this increment, one used in your report, about which you testified?

A. Yes.

Q. And the other used on the plate?

A. Yes.

Q. I understand you to say that the difference which would come from using the one method of computation rather than the other would not amount to more than 1/16 of an inch?

A. That is right. I want to explain that a little further. Most of these discharge lines are doubtless curves instead of straight lines. There are several reasons for that. There are so many more forms of curves than there are straight lines, only one straight line, the chances are always that it

may not be exactly a straight line. Unless you are splitting hairs, or trying to get down to the last refinement, you are not warranted in using curved lines. I might illustrate that by considering the surface of the earth or the surface of a small pond. We think of that as being a perfectly straight line across. We know it is simply an arc on the globe, of the circle of the earth; it is curved, but substantially and for all practical purposes it is a straight line.

Q. That is if the radius of the circle was big enough, the curved part becomes practically a straight line?

A. The curvature is so slight it does not in any way negative the substantial accuracy of using a straight line so far as arriving at the lowering of the lake levels is concerned.

Q. And for that reason these lines were drawn on the plates which you prepared for the purposes of this case in the interest of simplifying the operation?

A. To simplify the process, that is all.

Q. Is there any further statement you have to make with reference to this increment?

A. I did not give the increment in the International Bridge Section.

Q. Just give that now?

A. Between elevations 569 and 570 of Lake Erie, the increment is 19,540, and between 574 and 575, it is 23,510.

Q. Now we will take up Lake Erie?

A. The effect on Lake Erie of the diversion of 4,000 cubic feet would be about 2¼ inches.

Q. Upon what do you base that?

A. That is based on my work on the Niagara River and my knowledge of the results obtained from that, which is corroborated by the charts.

Q. And by the later observations in 1908?

A. And by the later observations. Yes, those were made under my direction as Principal Civilian Engineer of the Lake Survey. The planning of the work of the preservation of Niagara Falls, the hydraulic work there, was part of my work, and the initiation of it.

Q. What would be the effect on the Niagara River?

A. At Austin street, which is just below Black Rock, about 82 per cent and at Chippewa which is just above the rapids at Niagara Falls about 56 per cent of the lowering of Lake Erie. The lowering at Suspension Bridge or in the pool below the Falls and above Suspension Bridge, would be about 230 per cent, and in the whirlpool about 250 per cent.

Q. What would be the effect of the lowering due to this diversion at Chicago upon the Detroit River?

A. It would be lowered. In the vicinity of the Lime Kilns on the lower river it would be practically the same as in Lake Erie. And as you go further up the river, up towards St. Clair, it diminishes slightly.

Q. What would be the effect of the lowering by this diversion in Lake St. Clair and in the St. Clair River?

A. Computations made by the Lake Survey indicate about 41 per cent of the effect of Huron present on Lake St. Clair and about 45 per cent of the effect of Lake Erie.

Q. And to get the total effect you would take the sum of those two, would you?

A. About 86 per cent of the mean of the two lowerings would give it very closely.

Q. Eighty-six per cent of the mean?

A. Eighty-six per cent of the mean would give it very closely. That is on St. Clair the mean of the effect on Erie and Huron. Other computations show 37 per cent of Huron and 44 per cent of Erie, and that would indicate about 81 per cent of the mean. Perhaps 80 per cent might be a safe statement to make on that, or an average statement, 80 per cent of the mean.

Q. Are those computations made by the Lake Survey published?

A. The computation made by Sabin, the former of the two I give, is published in the 1900 report, page 5398.

Q. Is that the last computation made by the Lake Survey?

A. The computation by Mr. Ray, the latter of the two, I think is as late as anything we have.

Q. Those are the two you had in mind when you were testifying?

A. Yes.

Q. The only thing I wanted to bring out for the information of the gentlemen on the other side was as to whether or not these computations were published and if they were we would give them the references in the record?

A. Mr. Ray's computation has not been published.

Q. But Mr. Sabin's has.

A. And I want to say in regard to getting at the distribution between Huron and Erie as to the percentage of the effect of each, it is a little indeterminate. The total effect on Lake St. Clair, if the effect on Huron was 2¼ inches and the same thing on Erie, 80 per cent would be a very close

approximation to the truth of the effect on Lake St. Clair. But the nature of the reduction with varying gauge readings, is such there is some indetermination as to where the effect comes from, Huron or Erie. The effect of Erie comes as backwater and the effect of Huron is that of less water passing through Lake St. Clair. Less backwater tends to increase the outflow through the St. Clair River, so the thing is a little complicated.

Q. Have you made measurements on the St. Lawrence, of the same nature?

A. Yes, I made measurements in 1900 and 1901.

Q. What were the details of those measurements and the extent of them?

A. A hydraulic section was taken at Point Three Points, which is about twenty miles below Ogdensburg, and very close to the narrowest point in the river, where the conditions are exceedingly favorable for accurate measurements. The river at this point is about 1,700 feet wide and we had seventeen stations or panels on that river. The detail is much the same as the measurement of the Open Section of the Niagara River. We made 92 measurements there and 26 measurements were made at the same place by Mr. Moore during the past season, under my direction. During the winter of 1901, February, 1900, I measured a second section in the St. Lawrence River above Ogdensburg where the river is three-quarters of a mile wide.

Q. How is that section designated?

A. Nevins Point section.

Q. Were those winter measurements?

A. Those were made through the ice in the winter season. As I recollect it, we had twenty stations there or panels, which were 200 feet in width. The current had a mean speed of about one foot per second on this section and the depth I believe was in the neighborhood of 60 feet, mean depth 51 feet. We made these measurements for discharge there. The conditions for soundings, of course, on a section of that kind were very excellent for accuracy; and the conditions for velocity measurements were not as good; the slow velocity of one foot per second is more difficult to measure. The winter measurements checked the summer measurements within less than one per cent.

Q. Was the work which you did on the St. Lawrence River embodied in any one of these plates that has been prepared here?

A. The winter measurements?

Q. Yes.

A. You mean the summer or winter measurements?

Q. Either one of them?

A. The 93 measurements of which I have spoken are incorporated on Exhibit 2; those made at the section Three Points.

Q. And the winter measurements check with the others that you have stated?

A. They corroborated the summer measurements so far as volume is concerned. The range was not sufficient to determine anything regarding the increment.

Q. What would be the effect of the diversion of this water at Chicago upon Lake Ontario and the St. Lawrence River?

A. It would lower them; lower Lake Ontario and the St. Lawrence River to the Gulf of St. Lawrence.

Q. And to what extent?

A. The river at Ogdensburg, for 4,000 cubic feet, would be lowered 1¾ inches; and substantially the same on Lake Ontario. In the lower river in the approach to the Morrisburg Canal above the Rapide Plats, it would be 50 per cent. greater, 150 per cent. of that. I am stating this roundly. Lake St. Francis, as I remember it, the lowering would be a little less, but that is in Canadian territory, and I do not know that we need to go into that.

Q. You have referred once or twice during the course of your testimony to the building of the Gut dam in the St. Lawrence river?

A. Yes.

Q. And the measurements made for the purpose of determining the effect of that upon the increment and the volume of outflow. I wish you would state a little in detail what the facts about that are?

A. I did state it.

Q. Is there anything in addition to what you have already stated?

A. By means of the measurements at the Three Point section, we write out the outflow relations for the river over the Rapide Plat. That is another weir and outflow, just the same as the Galops Rapids is above, and we did the same thing, also at the Long Sault Rapids; so we have now the Galops Rapids, the Rapide Plats and the Long Sault Rapids. There is water passing over three different weirs. We calibrated these three weirs. The Galops Rapids Weir was interfered with by the building of the Gut dam, but the other two were free to meas-

ure the water, so the loss of outflow in the Galops Rapids was shown by a lowering of the water at the head of the Rapide Plats and the head of the Long Sault Rapids. The lowering appeared as the dam went in; it is very determinable. I ought to say in this connection that preceding the building of the Gut dam, I made a report on what the effect would be if they did build that dam.

Q. Based upon what?

A. My general knowledge of the conditions.

Q. And upon observations that had been made before that time, and general methods?

A. Yes, based upon the discharge measurements of the St. Lawrence River. The conditions were such that an accurate statement could not be made. We had to scale off the cross-sectional area of the Gut; we had the soundings there.

Q. Your computations were borne out, were they, by the actual observations?

A. It came within the limits stated. The actual rise of Lake Ontario by reason of the Gut dam was about five inches.

Q. You used a phrase that I think counsel on both sides would like to have you explain a little more fully. You spoke of calibrating the weir?

A. That is simply taking the discharge measurements and gauge readings at the same time; we get a relation between the gauge height and the amount of flow. It does not have to be necessarily in the lake; it can be in the river at any point. We have calibrated the weirs of the Niagara River at the head of the Rapids, and again at the Suspension Bridge and the Whirlpool, as I have stated earlier. Each rapid in a river, where there is a pool above it, becames a measuring instrument to estimate the flow of the river. While you measure in one place, the same amount of water goes through the whole river; if you have gauge readings at different points, you get the relation between the gauge readings for any point and the volume of outflow, and you can make a plat, such as in this case, Exhibits 1 to 4.

Q. What do you say as to the precision of river gauging done by the Lake Survey?

A. I consider a discharge measurement, or rather a series of them, to have a precision of 1 to 2 per cent.

Q. What is the reason why you think it has that precision?

A. That is in volume, not increment; the precision of the increment is not as great, perhaps 10 per cent. And as I have already stated, in the case of the St. Clair River, the incre-

ment may be an error of as much as 25 per cent. The reasons for my belief in the precision of volume is the corroboration that has invariably accompanied the measurement of duplicate sections, that is, the measuring of two sections in the same river. I speak now of the recent Lake Survey work, the work since 1896. In the Niagara River, as I have already testified, the second section corroborated the first within about 1.3 per cent. The precision of the summer measurements on the St. Lawrence River were corroborated by the winter section. The measurements on the power canals at Niagara Falls, made by Mr. Moore, concerning which he testified yesterday, as these were made under my direction and with my knowledge, I presume it is proper for me to state those?

Q. Certainly.

A. The second section corroborated the first on the Niagara Falls Power Company's canal within half of 1 per cent., and in the case of the hydraulic canal, that is the Schoelkopf Canal, the second section corroborated the first within 1.3 per cent. In the St. Clair River, the measurements made under my direction by Mr. Moore in 1908 corroborate the earlier measurements within 2 per cent.; show about 2 per cent. less flow than in the earlier measurements. The evidence given by these measurements at two sections on a stream, canal or river, are very strong confirmation to my mind of the correctness of the method employed. In 1906, I urged upon the Principal Assistant Engineer of the Lake Survey the advisability of making tests of the current meters, to see whether or not they did give the true velocity of the water. I thought the Lake Survey had so many velocity measurements that in its own records it ought to have a test of the current meters, and to get at the clear truth, to apply a correction for the meters or have a co-efficient of correction, so that our data would be gotten down to the limits of precision, which was what we were working for in all respects. And I made tests on the Detroit River at Fort Wayne, or abreast of Fort Wayne, to find out whether or not the velocities shown by the current meters were the actual velocities at which the water was moving, and 76 measurements, traverses of colored water over a 200-foot base, showed that the current meters indicated the same velocity as the colored fluid was traveling, within one-fifth of one per cent. As the result of those observations my report to the Lake Survey was that we needed to make no corrections of our discharge observations for the meter error.

I can go into that more in detail if it is necessary. I have a report on the subject here, as a matter of fact.

Q. You have your report here, have you?

A. Yes, I have it.

Mr. Wilkerson: We will have it marked as an exhibit for identification, and if you gentlemen want to refer to it, or want to incorporate it in the record, you can do that hereafter. The paper produced by the witness is marked Exhibit No. 6 for identification. It is headed: "Current Meter Tests."

Whereupon document referred to by counsel was marked for identification "Government's Exhibit No. 6."

Q. In order to have a complete explanation of your reasons for saying that the measurements made by this current meter are accurate, you may read such portions of that paper as will explain, or add to what you have said already, and you may have the entire report, if deemed advisable hereafter, incorporated in the record.

A. In making these tests we used two of our steel pontoons. They are part of our pontoon sweep. These have overhanging decks and we extended the overhang of these pontoons further still so that we could drop a meter twelve feet beyond the hull, so as to get away from the hull influence. Then we took two of these pontoons and hung them in the current, one 200 feet below the other; the first suspended by an anchor above, and the second suspended from the first by two galvanized iron wires. On one of these wires a 200-foot length was laid off and beads were soldered on, and this 200-foot length was tested by steel tapes when the system was hanging in the river, or floating in the river current. Then we put one of two current meters about abreast of the upper up-stream bead, and the other one just below the down-stream bead. We injected with a bicycle pump about four ounces of a strong fluid bluing, or a strong solution of analine red; we tried both. This was injected in the river above the up-stream meter, and in injecting it, the bicycle pump was moved along at about the current speed, so that no change in the velocity of the colored water would take place. This ball of colored fluid, or the water itself which was colored by the injected bluing or red, was timed between the first meter and the second, with a stop watch, and the current meters were operated at the same time, which gave us two sets of velocities, the velocitiy shown by the colored fluid and the velocity indicated by the spinning wheels of the meter. If the two agreed, the test seems very

complete. I have already stated that 76 of these traverses, or 76 different colored balls going over the 200-foot base, the mean of these shows that the meter indications were within one-fifth of one per cent. of the velocity shown by the fluid.

These meters were rated immediately before the test on the still water base, following our customary methods.

Q. How do you rate a meter?

A. A meter is rated by moving it through still water over a 200-foot base, ordinarily. That is, a wire is stretched across a reservoir, or some still body of water, and on this wire are two beads soldered about 200 feet apart. The meter is suspended ahead of a boat, ordinarily ahead of a skiff, sometimes ahead of a catamaran or between the hulls of a catamaran. And in some of our rating, we even work on the ice, by suspending the meters through a slot in the ice. The meter is made to traverse this 200-foot base at a large variety of speeds, that is, such a variety as we are likely to find, or do find, in the stream that we are measuring; and the propeller wheel actually shows the relative motion between the water and the instrument. And our test indicated that it does not make any difference whether the water is moving, and the instrument is at rest, or the instrument is moving and the water is at rest; the relative movement is what the propellor shows. In stating this, I make the reservation that the flowing water should be fairly smooth water. I do not mean to say you could go out in rapids and measure the velocity very closely, with a float, or anything else, or with a current meter.

Q. What do you think about the precision of your observations as to soundings?

A. That is well within 1 per cent. in all cases.

Q. Why do you say that?

A. That is involved also in the check of two sections of a river. If the soundings were not accurate, why the results would be likely to diverge on two sections. We have also sounded the same sections a number of times over, and the precision indicated is very great. That came out in the resounding of the spans of the International bridge. The difficulty of sounding becomes greater as the water is swifter and deeper; and in the third span of the International bridge the water is running about five miles an hour and is about 50 feet deep; and the second sounding corroborated the first within one-tenth of a foot, that is, the mean sounding. Then the St. Lawrence, the duplicate soundings there, come very close. I do not know just how close it was, but it was within a

tenth of a foot, the mean. The soundings are certain, as we make them, to be well within 1 per cent.

Q. What do you think about the precision of the observations which you made with the water gauges?

A. That cannot be expressed as a percentage, as that means very little; it should be stated as absolute. The water gauge readings as made by me for the Niagara River and for the St. Lawrence do not have an error exceeding one-fourth of an inch on the water surface. And when I say that, I mean for individual discharge measurement, the mean, or the readings which give the final result are less in error than that; I should say within one one-hundredth of a foot, or one-eighth of an inch. I have already stated it is my opinion on the St. Clair River that the water level transfers may have made an error of as much as one-tenth of a foot, in some of the readings. There are some cases on some of our gauges in the lakes where settlement of a pier on which they are located may temporarily give us incorrect readings; but we test our gauges twice a year with a spirit level, we have inspections, and as I have already said two water gauges on one of the Great Lakes with a water stretch between, that forms a leveling instrument; and we are constantly watching our gauges. As an illustration of how we can detect from one gauge an error in another, I might state a case that occurred on Lake Erie. The District Engineer's office maintains a self-registering water gauge of the Lake Survey type at Amherstberg. The Lake Survey maintains a similar gauge at Cleveland. Upon examining the records at Cleveland and Amherstburg, I found that something was wrong with the Cleveland gauge. I told them that the Cleveland gauge was showing one-tenth of a foot too low; that is, about an inch and a quarter too low. An examination of the Cleveland gauge was made and they found a small leak in the float. Upon emptying the float and testing the gauge, the actual error of the gauge was found to be from that cause 11/100 of a foot, that is, an inch and three-eighths. That indicates how from one gauge we can state whether or not things are going on right at another; and a process we are watching pretty carefully.

Q. I do not know whether I quite understood what you said about the settling of the piers?

A. I mean that if a water gauge were located on a pier as at Milwaukee, and that pier should settle as piers sometimes do, that gauge might give an incorrect result for a while; but we are watching for those things.

Q. Are those errors involved in the discharge measurements?

A. No, those do not involve the discharge measurements. During discharge measurements, we are watching things with a care that we do not exercise at other times; everything is checked up very carefully frequently.

Q. You are just stating something that might happen, that did not happen in connection with any of these measurements that we have here under consideration?

A. No, that don't affect the measurements under consideration.

Recess to 1:30 p. m.

Parties met at 2:30 p. m.

Q. In connection with these plates about which you have testified, you made reference to the number of observations which had been made, laying stress upon that as one of the things to be taken into consideration in your opinion as to the accuracy of the result. I wish you would explain a little more in detail just what the effect of considering a large number of these observations is in eliminating any mistake which might appear if only one or two or three observations were taken?

A. In the case of the Niagara River, including both the International Bridge section and the open section we have 353 individual, separate measurements of the volume of flow of the river. The length of time over which these observations extended gave us a considerable range of Lake Erie stage. We have nearly four feet of range. The number of observations mean that we used not only a number of different current meters, individual meters, in making the measurements, but the rating of these meters was slightly different from time to time. That is, we would rate the meters and make a certain number of measurements; rate the meters again and make some more measurements and so on. And in the end this has the effect of eliminating instrumental error. Then the other minor errors that might enter into the work, there might be an error in an individual case in the gauge reading; there might be a clerical error in taking it off, but in the great multiplicity of measurements these are eliminated.

Q. Is what you said with reference to the number of observations in connection with the determination of this particular result a thing that is peculiar to this computation, or is it something that applies generally to scientific observations?

A. It is a fact that is general; the number of observations, within limits, increases the accuracy or the precision of the result. I want to make one correction in a statement that I made, I did not make it specific, on the increment of the Niagara River.

Q. You may make that correction.

A. I stated the possible error in the increment of the St. Clair River is 25 per cent., and in my judgment it would be below the increment as shown; that is, the increment would be less rather than greater, for reasons that I gave. And on the St. Lawrence River, the error in increment is probably 10 per cent., but in the Niagara River not over 5 per cent. That 5 per cent. is what I failed to state.

Q. When you were speaking of the degree of precision?

A. Yes, and I perhaps should give the reason why I say that, the range of four feet, in the case of Lake Erie, on the Niagara River, gives a high precision in the trend of the line, and on that the increment is based. In the case of the St. Clair River, with a less range, the exact inclination of the line is less determinate; that is one of the factors. On the St. Lawrence River, we had a range of about 2.4 feet which gave us a good determination, but not as good as the range of four feet on the Niagara River.

Q. What would be the effect of the diversion of this 4,000 cubic feet per second at Chicago on the water power in the St. Lawrence and Niagara River.

Mr. Williams: I object to that, for the reasons previously stated.

A. The fall of the Niagara River from the intake of the Niagara Falls Power Company to the level of the river at the portal in the gorge is about 220 feet. That means for each cubic foot per second of water 25 horse-powers, theoretical horse-powers; that is the potential in the water. For 4,000 cubic feet that would be 100,000 horse-power. The efficiency of turbines and the conditions at Niagara Falls are such that we may expect as high an efficiency as 80 per cent. of that. I should say 80,000 horse-power would be the amount of power in the fall at the cataract, that is, in the rapids above the cataract and at the cataract of the Niagara River. That is on the turbine shaft. The Whirlpool Rapids and the lower rapids of Niagara River have an additional fall of about 88 feet, and 4,000 cubic feet per second would mean 40,000 horse-power theoretical, or 32,000 on the turbine shaft. On the St. Lawrence River the Long Sault Rapids alone has a fall of

about 50 feet, and the loss of horse-power there by the abstraction of 4,000 cubic feet would be somewhere in the neighborhood of 23,000 horse-power, or 18,000 horse-power on the turbine shaft,—assuming the same efficiency there. The investigations, the hydraulic investigations of the Niagara River, which were very extensive and are still in progress, for the preservation of Niagara Falls, has a bearing on the matter of water power at that point. We were ascertaining in that investigation the effects of diversions of water for power purposes.

Q. Have you given any consideration to the question of the effect of ice on these rivers, the St. Clair, Niagara and St. Lawrence, on the outflow through the rivers?

A. In my report of 1902 I make a discussion of the ice effect on the St. Lawrence River; and it is found there that the month of December the ice has no retarding influence on the outflow. January, February and March are the months and the only months that have an influence on the outflow. In the Niagara River, the effect of the ice is less marked, and some discharge measurements were made during the ice season. We made 27 measurements during the winter season, and those show somewhat smaller flow during the winter season. The observations on the Niagara are not extended enough nor the conditions constant enough to determine the ice effect. As regards ice on the St. Clair River, if it is proper to do so, I would like to read an extract from the report of the Deep Waterways, 1896.

Q. You refer now to what report?

A. This is the earlier Deep Waterways Board, not the one referred to in my former evidence.

Q. Let us get the exact title of the book?

A. This is United States Deep Waterways Commission, bearing the date: Washington, Government Printing Office, 1897. The Commissioners were James B. Angell of Michigan University, John E. Russell and Lyman E. Cooley. Cooley, I believe, is the technical man, and he is also, I think, or has been, connected with the Drainage Canal. It is page 21.

Mr. Williams: Before Mr. Shenehon reads that, I would like to have him state whether or not the opinions expressed there or the facts stated there coincide with his own opinion.

Mr. Wilkerson: I thought I would have him indicate the portions of the report to which he refers, and then have him make such statements based upon his own investigation as he

sees fit. I thought that was preliminary to some statement he was about to make. Am I correct in that?

Mr. Williams: There is a part of the report he desires to make his own statement. I have no objection to that but I want Mr. Shenehon's judgment and not that of these gentlemen, unless he has made sufficient investigation so that he feels he has an opinion which coincides with the opinion expressed in the report.

Mr. Wilkerson: Let us first have the parts of the report. Read the parts of the report, Mr. Shenehon; then we will see what develops after you read it?

A. The paragraph marked E on page 21: "The average ice season in the Straits of Mackinac is from January 6th to April 15th, or ninety-nine days. It will thus be seen that through navigation is limited by the closing of Lake St. Clair and the opening of Mackinac, or from December 17th to April 15th, a period of one hundred and nineteen days. The Mackinac ice is understood to be largely the accumulated drift of the two lakes."

On page 199, the same report: "The average dates of closing and opening of St. Clair Flats Lighthouse, Michigan, is December 15th, and April 4." That, I believe, is from official records, and the tabulation goes into that more in detail. My own belief is that the ice season on the St. Clair River is ordinarily between, say December 15th and April 15th. Occasionally the ice does last through April, and I believe there are some records of its holding into May; 1901 was a case in point.

Q. What is that ice effect?

A. It is a lessening of the discharge through the ice retardation.

Q. What is the effect of that upon the lowering which would be caused by the diversion at Chicago?

A. Whatever retardation comes from that and whatever lifting of the Lakes Michigan and Huron there is, is something I should say navigation was entitled to irrespective of the Chicago Drainage Canal. If the ice shuts off half the flow of the river, as it does at times, the presumption is—and I state this only as a presumption—that the increment is lessened. And if the increment is lessened during that period, the tendency of Lakes Michigan and Huron is to lower at a greater rate than indicated by the open season increment. By that I mean that if the increment becomes 12,000 instead of 24,000, and that should be a continuous condition, the low-

ering would be four inches for 4,000 instead of two inches for 4,000; and during that period that the ice is in place, the tendency of the lake to lower is greatly due to the Chicago Drainage Canal. It is rising at the same time, but the drainage canal effect is towards a greater lowering than indicated by the open river flow. We have no observations that very clearly show that is the case with the increment, and I state it as a presumption. It looks that way to me.

Q. Is there anything else now that you have in mind, with reference to the ice effect in these rivers? Is there anything you have knowledge of that you have not stated?

A. I do not recall any other fact.

Q. You have covered that condition?

A. I think so.

Q. What knowledge have you on the subject of scouring in the St. Clair River?

A. The observations made under my direction by Mr. Moore last fall, 1908.

Q. Did you follow that work closely?

A. In a general way; not very closely. I knew the results.

Q. I mean with reference to the methods used?

A. Yes, I instructed him regarding the methods to be used and the sections to be sounded.

Q. And the observations which were made were the ones about which you testified yesterday, as the result of your directions?

A. Yes.

Q. What was the result of that investigation?

A. No scour; taking the sections as a whole there is no scour indicated. By that I mean no lowering of the river at that place in the period between 1901, I think, and 1908. I believe in one section the bottom seems to be a little deeper and there is a little less water, but there seems to be no evidence in the whole thing of scouring. There is a movement indicated of certain parts of the river bottom. I know of no evidence of scour in the St. Clair River as a whole, or in the head of the St. Clair River, that is making the discharge any different now than it was in 1898. The discharge observations made in 1908, the corroboration of those with the earlier discharges seems to be evidence of no change of regimen in the river.

Q. What can you say as to the effect on Lake Erie of the diversions at Niagara Falls?

A. Up to the present time it is practically nothing; that is,

Lake Erie has not been affected; while the diversions have caused some lowering of the river above the rapids, certain other elements have tended to compensate that lowering; and any lowering of Lake Erie that has resulted is exceedingly small.

Q. What other outlets in Lake Michigan and Huron are there other than the St. Clair River and the Drainage Canal?

A. I know of none.

Q. Is that a subject to which you have given some consideration?

A. In a humorous way.

Q. What do you say as to that for Lake Erie and Lake Ontario?

A. Lake Erie, of course, has the Erie Canal and the Welland Canal in addition to the Niagara River; and Lake Ontario has no other outlet than the St. Lawrence River.

Q. When you say you do not know of any other outlet, by that do you mean that nobody claims to have knowledge of any such outlet as that?

A. I know of nobody.

Mr. Williams: Let the record show an objection to the counsel asking the witness as to what somebody else claims.

Mr. Wilkerson: Well, what is the present state of knowledge on that subject, so far as you know?

A. I know of no claim that there are any subterranean outlets, if that is what you refer to.

Q. I mean by anybody who claims to have any knowledge on the subject.

A. I know of nobody that claims that there is such an outlet.

Q. In this work in which you have been engaged, have you had any occasion to give consideration to matters relating to data on rainfall, evaporation?

A. Not large consideration, no.

Q. Well, have you given any consideration to it?

A. It has been brought to my attention. I understand that it is one of the elements in an observation of lake levels, if you have adequate data, to take the rainfall and the run-off and the evaporation, and co-ordinate them with the discharge summer and winter and arrive at the lake level. I have never thought that in evaporation, particularly, we had any data that would permit us to figure in that way.

Q. You have studied it with a view to reaching a conclusion as to the reliability of those observations, have you?

A. Yes, I have an opinion on that.

Q. For such a purpose?

A. Yes, for such a purpose. I have an opinion on that.

Q. I wish you would state what that is and your reasons for it.

A. Observations on evaporation have been conducted in reservoirs on shore, and they are not extensive as I know them. We have no observations in mid-lake areas, on an area of the lake that is surrounded by water on all sides is likely to be very different from evaporation in a reservoir on shore. And any attempt to state with any definiteness what the evaporation is on any one of the Great Lakes has little weight in my opinion.

Q. I think you covered perhaps completely the point of the reliability of the data on outflow during the ice season, did you not? A. We haven't very definite knowledge for any particular year as to what the effect may be. Sabin on the St. Clair river made observations for flow during ice periods, and I believe that is all we have, on the St. Clair River. I have rather definite opinions on the St. Clair River, you understand, as I before testified. But one of the years that Sabin considered and made observations in was the year 1901, which was the most abnormal year as regards ice that I have any knowledge of; and I say that, after an examination of the elevation of Lake St. Clair with respect to Lake Huron. The effect of ice is to build up Lakes Michigan and Huron at the expense of Lake St. Clair, and after a period of this ice retardation, Lake St. Clair naturally is low; its supply has been cut off and the water drawn out of it. The same is true in a lesser degree of Lake Huron. 1901 is doubtless the most abnormal of the recent years as regards ice conditions; that is the ice retardation was greatest and continued longest into the spring. As regards rainfall, the absence of rainfall, stations upon the open lake areas themselves and the thin distribution of stations through the Canadian part of the water shed make the use of rainfall observations rather uncertain, and when I say that, what I mean is, that I do not see that observations on rainfall and evaporation and the winter flow of the St. Clair River could be used to detect the presence or absence of the effect of the present flow of the Chicago Drainage Canal. The two or three inches that might be the effect of the Drainage Canal, or that would be the effect of the Drainage Canal, masked by the conditions.

Q. What have you to say as to the effect of the fluctuations

of the lakes due to natural causes in making this loss of two or three inches which would result from the diversion of this water more or less serious?

A. I do not see that the fluctuation has any bearing on the case.

Q. Why do you say that?

A. Because whatever the water level is, if it had been lowered, say two inches, by a diversion, you would still be short your two inches where you needed it, in the critical places. The natural fluctuations due to winds and to seasonal conditions are independent of the drainage canal, and the loss in draft is always measured by the amount of the lowering; you are always two inches closer to the bottom in such a case, whether the lake is raised or whether the lake is tilted up or not; you are always two inches closer to the bottom than you would be otherwise; and when you are running over critical areas two inches may count. Perhaps I should say: when you are attempting to run over critical areas.

Q. As to the effect of the loss of two or three inches in the draft of vessels, do you give any consideration to that, do you add anything to the statements that have been made already on the subject, and do you know the statements that have been made?

A. I have been familiar with the subject for some time and I have spoken of the loss of draft or the loss of carrying power on one of the large lake freighters, due to loss of draft, as about a thousand tons (of 2,000 pounds) to the foot. That would be 83 1/3 tons to the inch. That is an approximate statement. That is, between say 19 and 20 feet; that is near the load limit.

Q. What do you mean by critical areas, critical places?

A. The areas that are shallow, and where the vessels passing are close to the bottom. In that I should extend it to areas where vessels will be close to the bottom when the deeper drafts on the lake, that are certain to come, are realized.

Q. I wish you would explain that a little in detail, telling us what some of these critical places are now; what changes there are likely to be and what the critical areas are that will be affected by that situation; and where the points are that this difference of two or three inches will make a difference in navigation?

A. The floor of the Poe lock is one of the critical points at the present time. The north end of Lake Michigan is an intricate place for navigation, with a good many shoals. And

when a shoal is two inches nearer the surface by the lowering of the lake level, it becomes more of a menace. The vessels in thick weather sometimes get astray, and loss of draft on a shoal may mean a very serious thing to a vessel. The Manitou Passage in Lake Michigan is a place of the same kind; Gray's reef passage, Sturgeon Bay canal is a critical point, and the entrance to Green Bay is a place where a vessel is likely to get into trouble. The foot of Lake Huron approaching the St. Clair River is another place; also Lake St. Clair; the foot of the Detroit River and Bar Point, which is just beyond the Detroit River, and the west end of Lake Erie; and more particularly that part of Lake Erie leading towards Toledo. The west end of Lake Erie is shallow. When the new lock is built at the Sault, giving greater drafts, the Poe lock will cease to be a critical point; and when the Livingston channel is built in the main Detroit River that will cease to be a critical point. But these others remain; these are fixed and that is what I mean by saying that the points that are critical at the present time, after improvements have been made permitting deeper navigation, those that are safely passed over now, two inches of lowering will reduce their efficiency.

Q. With reference to these plates that you have explained Mr. Shenehon, and with reference to the statements which you have made as to the effect of the diversion of this water, is there anything further that you have to add that suggests itself to you now, or any reports you have in mind that you wish to refer to, that bear on this matter? You think you have covered the ground now as far as you recall?

A. I think so.

Mr. Wilkerson: If there is anything in the way of explanation, or anything Mr. Shenehon wishes to refer to or put in, after reading over the testimony, I can recall him for that purpose.

Mr. Williams: Yes.

Mr. Wilkerson: With that reservation, you may cross-examine.

Mr. Williams: Before proceeding with the cross-examination, we have now introduced as an exhibit this chart showing lake levels. What I desire now is to have it appear in the record that the data from which this chart is compiled, in the way of published data concerning lake levels may be used by us without any objection as to its being the best evidence. The lake elevation observations are shown in the published reports, subject of course to the records from time to time. We

do not want to be obliged to call the men who read the gauge, if we want to show some of those lake elevations as published.

Mr. Wilkerson: You mean you would like to have the opportunity of checking this as against the data?

Mr. Williams: You may put it that way, although we have no question about it. But suppose we wish to make the computation concerning something or other on these lakes, where the scale is not sufficiently accurate to get what we want. What we want would be the opportunity to go back to the table of monthly means, which they have, and to use those tables rather than this chart.

Mr. Wilkerson: I suppose as to any particular data, you can furnish, on reasonable notice, the data which you have in the office?

Mr. Shenehon: Yes.

Mr. Wilkerson: I can see no objection to that.

Mr. Williams: All we want is, if we wish some of that data we will not be obliged to verify it by calling the men who made the reduction, but it will be accepted as evidence.

Mr. Wilkerson: I take it we can have the same understanding with reference to that as we had concerning the data on which the charts are based.

Mr. Williams: That is all we want.

Mr. Wilkerson: In other words, we take the records of the office here with the same effect as if the man himself were put on the witness stand and produced the data?

Mr. Williams: There is one other point: There is a regulation of the Engineer Corps that they shall not give out information in matters of this kind to parties engaged in suits against the government, so that it must be agreed to here.

Mr. Wilkerson: Of course you are entitled to it, because you would have the right—

Mr. Williams: I do not think that is the government's attitude, but I understand there is that rule.

Mr. Wilkerson: This chart having been produced, you are entitled to the data if you want it, for the purpose of cross-examining the witness who produces it. All that you have to do in order to get any data that has any bearing on this case is to let us know what the particular data is, and I think I am safe in saying we will let you have it, if it is in existence.

Mr. Shenehon: I see no reason why that should not be done.

Cross-Examination by Mr. Williams.

Q. The Livingston channel to which you referred is an improvement now in progress on the Detroit River, is it?

A. Yes.

Q. What is the nature of that improvement?

A. The Livingston channel is a proposed channel under improvement at present, passing to the westward of Bois Blanc Island. The present channel runs to the eastward of Bois Blanc Island. And this channel is intended as a channel for downbound traffic, for heavy laden traffic coming down. It starts in above the Lime Kiln crossing above Stony Island and runs out to the Detroit River light.

Q. Is that in American or in Canadian waters?

A. It is in American waters.

Q. What is the extent of the improvement; in other words what are the dimensions of the proposed channel, what is the proposed depth and width?

A. Three hundred feet width, and about 24 feet depth.

Q. What is the present depth of water along the course of the proposed channel; that is the original depth without the improvements?

A. Anywhere from 4 feet to 21, 22 feet, 27 feet in places there.

Q. This improvement is being carried on by what method, dredging?

A. The rock cutting in the vicinity of Stony Island is cofferdammed, and being taken out in the dry.

Q. And the remainder of it?

A. The balance is being taken out by dredging.

Q. What is done with the spoil, the excavated material?

A. It is being put into spoil banks, and I believe into compensating the loss of increased flow due to that channel in the river.

Q. What in your opinion will be the effect of the construction of the channel on the level of Lake St. Clair?

A. I cannot form an opinion on that, because I do not know the extent of the compensation. I think the intention is to put sufficient compensation in to take care of the additional channelway, or flow area, so that no change will be made in Lake St. Clair.

Q. Will the cross sectional area of the Detroit River be increased by the construction of this channel?

A. It will be lessened, as I understand the compensation.

Q. What compensating works are contemplated, other than the depositing of the excavated material in the shallower parts of the river?

A. None that I know of.

Q. If there are no other compensating works contemplated, would you say that the excavated material deposited in the shallow parts will take up more space and reduce the cross sectional area any more than it did in its original location?

A. I have not given sufficient study to that to give an intelligent opinion on the subject.

Q. Assuming, Mr. Shenehon, that in the construction of this channel the excavated material is taken out and deposited in the shallow parts of the river, and that nothing else is done for the purpose of compensating for the new channel, what is your opinion as to the effect of that work upon the amount of water flowing through the channel, as changed by the new work?

A. I have not investigated that sufficiently to give an opinion that would be of any weight.

Q. You have no opinion then, I assume, as to the effect of this work upon the level of Lake St. Clair, or upon the depth of water over the critical areas?

A. In Lake St. Clair you mean, and in the Detroit River?

Q. Yes.

A. My only understanding of the thing is that the compensation will be complete.

Q. And that therefore there will be no change?

A. There will be no change.

Q. In the cross sectional area, or the amount of water—

A. In the level of Lake St. Clair.

Q. —or the amount of water flowing through the Detroit River as modified by this channel?

A. Yes.

Mr. Wilkerson: Who is constructing this channel?

A. The United States engineer office for this district.

Q. It is a government improvement, is that right?

A. Yes. I should add that investigations regarding the water levels of the Livingston channel have been instituted by Col. Townsend and Major Kellor; and Mr. Ray has made some figures on the subject. I have given little attention to it myself. The intention is, however, to compensate.

Mr. Williams: You have testified with reference to the Neebish channel in the St. Marys River?

A. Yes.

Q. What is the nature of that improvement?

A. That is a new downbound channel in the west Neebish of the St. Marys River.

Q. What was the original depth of water approximately in that part of the river where this channel was constructed?

A. I could not testify to that without looking it up.

Q. Passing that for the moment, what is the nature of the dimensions of the new channel? Is it completed?

A. Yes, it is completed.

Q. When was it completed?

A. It was completed in winter of 1907-8.

Q. What are the dimensions of the new channel, width and depth?

A. I believe it is 300 feet wide and 22 to 24 feet in depth. I am not certain of the depth.

Q. What was the nature of the excavation there?

A. That was rock, with mud in upper approach.

Q. Rock excavation?

A. Yes.

Q. What was done with the excavated rock?

A. I am testifying in regard to this without having seen it since it was started, or completed; simply on general knowledge. I have not followed the thing closely and my testimony cannot be very accurate regarding the dimensions there.

Q. Do you know whether or not it was intended or attempted to make any compensation there?

A. I think not.

Q. What was the effect, so far as you know, of the construction of the channel upon the level of the water at the foot of the locks?

A. The effect was to lower it.

Q. To what extent?

A. I am not positive. I do not think the data is sufficient to enable us to state accurately. It may be as much as two or three inches; I believe it was fully that.

Mr. Wilkerson: That was a government improvement also?

A. That was a government improvement, yes. As regards compensation in St. Marys River at the West Neebish, I think an attempt to compensate there would have created currents in the channels that would have made navigation difficult.

Mr. Williams: The original depth was the question that you did not wish to answer until you had seen that document which you now have?

A. Make that 24 feet.

Q. That is for the original depth?
A. No, that is the finished channel.
Q. The finished channel?
A. Yes.
Q. Now the original depth?
A. The original depth is about 15 or 16 feet.
Q. What is the range from the minimum to the maximum, just generally?
A. From four feet, and some rocks are indicated above water so we will have to call it zero; from three to four feet, to 16 or 17.
Q. Now you have before you a map here showing another channel on the easterly side?
A. That is the middle Neebish.
Q. When was the work constructed?
A. The Hay Lake channel was opened about 1894, a little before the opening of the Poe lock. The Poe lock was opened in 1896, and my impression was that the—
Q. It was prior to 1896, that is near enough?
A. The Hay Lake channel was opened, the Northwest opened it when I went up on her, which was in the neighborhood of 1894. Some vessels were running through prior to that.
Q. Now, Mr. Shenehon, with the map before you, can you testify briefly what the original depth was along the course of the Hay Lake channel, and what the improvement consisted of?
A. That is the middle Neebish you are talking about now?
Q. Yes?
A. The original condition is not shown on this earlier chart here, but I should say it was not very different from the condition in the West Neebish. The old channel, the East Neebish, was the original channel, and they had 12 feet of water in the old days; and there was less coming up through the middle Neebish.
Q. What are the dimensions of the middle Neebish now?
A. That scales about 400 feet. I have not personally seen the middle Neebish, nor been very familiar with it since 1898.
Q. The depth of water through that Channel is what?
A. Twenty-two feet is indicated here.
Q. You testified, I believe, on direct examination as to the slope of the St. Marys River?
A. Yes.

Q. The slope from the foot of the locks to Lake Huron is about how much now?

A. Something over a foot. I said our elevations were not sufficient to accurately determine that; at least I have not personally looked into the matter.

Q. Do you know or have you available records from which you can ascertain what the change in that slope has been during the past twenty years, say since 1888?

A. From 1886 to 1890, the mean slope between the water at the foot of the locks and the Harbor Beach gauge is 1.99 feet, practically two feet. From 1891 to 1895, 2.40, 2.4 feet. From 1896 to 1900, 2.74 feet. 1901 to 1905, 2.14. Now that slope is in a measure, dependent on the amount of water going through the river; that has some effect on it, a lowering of stage of Lake Huron, as we stated in our back water effects, before.

Q. Was there any record prior to 1886?

A. Yes, they reach back to 1871, to 1875. That was prior to the improvements though there.

Q. Suppose we have them from 1871 down, if you have them conveniently before you?

A. Very well; 1871 to 1875—these are five-year periods—3.03; 1876 to 1880, 2.30; 1881 to 1885, 2.07; 1886 to 1890 you already have as 1.99.

Q. Now from 1905 to date, your information, you say, is not entirely accurate?

A. No, this is from a report dated 1906. I have not brought that up to date.

Q. Can you briefly indicate the improvements that were made these several periods, which caused the variation, or had a tendency to cause the variation in the slope. For instance from 1875 to 1880, there was a difference of about 7/10 of a foot in the slope. Was there any improvement constructed there at that time that might have had the effect of reducing the slope to that extent?

A. I know of none.

Q. Are there any of the variations in slope indicated by the figures that you have given that you would say in your opinion were attributable to any improvements constructed in the St. Marys River?

A. Perhaps I can get at what you are after by one single statement.

Q. That is what I would like?

A. I think it is very probable that the water has been low-

ered a foot at the locks by reason of improvements in the river.

Q. That is the several improvements?

A. Yes. At the Middle Neebish, there was some compensation; a dam was run through the shallow water, but I think the compensation was incomplete, and yet I speak without full knowledge of the hydraulics of that lower river. A compensation I think at Little Rapids was attempted also. I do not know to what extent it was effective.

Q. Has the effect which you have indicated as resulting from these improvements resulted in the lowering of the water over the mitre sills of the Poe lock?

A. Yes.

Q. To the same extent as you have indicated?

A. I should say a foot, yes. I will state that as strong as you like

Q. And that lowering would have the same effect upon navigation as the lowering caused by diversion at Chicago, which would be sufficient to lower the level of Lake Huron a foot, would it not?

A. I see no difference.

Mr. Wilkerson: You refer to that as in the St. Marys River; not over the lower lakes?

A. I refer to it simply on the floor of the Poe lock.

Q. Not over the lower lakes?

Mr. Williams: No, we do not understand it that way.

The Witness: In that particular case the alternative of introducing very swift current or accepting a lowering at the locks was presented, and the lowering at the locks, in view of a new lock, was considered the lesser evil.

Mr. Wilkerson: It was a choice between evils was it?

A. Yes.

Mr. Williams: What is the tendency of the several improvements now under way and in contemplation by the government, as to the lowering of the level of the upper lakes?

A. By the upper lakes you mean Michigan and Huron?

Q. All the lakes above where the improvement is either being made or contemplated?

A. You mean the effect on Lake Superior?

Q. Not the lake itself, but the effect upon the St. Marys River up to the foot of the locks, and the other lakes above where the improvement is being carried on. In other words, what I am getting at is: Isn't it the tendency of all the government improvements to lower the level of the lakes lying

above the point where the improvement is being made, and reducing the slopes?

A. I should say not.

Q. Are you familiar with the work done by the government in dredging at the foot of Lake Huron during the years 1889, 1891, 1892?

A. Not in detail.

Q. You are familiar with the fact that that work has been done?

A. Dredging has been done there, yes.

Q. Do you know what the tendency of that work has been upon the level of Lake Huron?

A. No.

Q. Do you know whether it had any effect?

A. No.

Q. You are familiar with the fact that dredging was done by the United States government in Lake St. Clair, during the years, 1893, 1894 and 1895?

A. I know dredging has been done, but not in detail.

Q. Do you know whether that work had any effect upon the level of the St. Clair River, and Lake Huron?

A. I do not know.

Q. Or either of them?

A. I do not know as regards amount; I should say a trivial effect would enter.

Q. There would be a tendency for it, would there not?

A. I should think so, yes; a small tendency to lower.

Q. Well, now, going back to the other question, wouldn't the tendency be in all improvements of this character to lower the level of the bodies of water lying above the point where the improvement was being carried on?

A. I should say the tendency would be on the side of the lowering rather than on the other side, but it is very small aside from the one case that I have testified about, regarding the water over the floor of the Poe lock. The tendency in creating channels has been to make a bigger opening, and a deposition of material elsewhere has tended to make a smaller opening there, and there has been compensation to a considerable extent; and that whole question of the lowering has to be taken altogether.

Mr. Wilkerson: These last dredgings you are speaking of now, do you know just where they have been made?

A. In Lake St. Clair?

Q. Yes.

A. In the neighborhood of the Flats and also at the foot of Lake St. Clair.

Q. Are those critical points?

A. Yes.

Mr. Williams: Assume that there was a natural channel 2,000 feet in width, with ten feet of water at the deepest point, having a slope of one foot in 10,000; the entire channel having a cross sectional area of 12,000 square feet. Then assume that the central portion of the channel was dredged to 20 feet in depth with a width of 240 feet, the excavated material deposited in the shallow portions so that when the improvement is completed the new channel has exactly the same cross sectional area as the original natural channel. What would you say as to the amount of water that would flow through the new channel as compared with the old, assuming that there has been no change in the slope. Mr. Williams has given you a diagram or sketch of the two channels such as are embodied in my question.

A. If I comprehend this question right, an approximate answer to this is that the amount of water would vary as the square root of 20 to the square root of 10. That is not accurate; it is simply an approximation.

Q. What I wanted to get was would the amount of water be increased or decreased?

A. For the same slope in the compact section, as compared with the shallow one?

Q. Yes.

A. The water would be increased, the amount of flow would be increased.

Q. Then if in a shallow channel a deep channel is constructed and the only compensation attempted is to deposit the excavated material in the shallow parts, so that the cross sectional area was not in any way decreased, the amount of water flowing through the new channel would be increased, assuming the same slope?

A. Yes, there would be more water, considerably more through the compact channel. That statement that it would be in the proportion of the square root of 20 to the square root of 10 was very approximate. It would be the square roots of the hydraulic radii.

Q. Your approximate answer would indicate an increase of about 40 per cent in the amount of water flowing through the same sectional area?

A. I think perhaps it would be a little less than that. There

would be decidedly more water under those circumstances; if the compensation was one square foot per square foot of cross sectional area, it would not compensate it.

Mr. Wilkerson: If they piled this up, so that they made the cross sectional area less, you mean?

A. I testified in the Detroit River the intention was to make compensation by making the area less. That is considered in the plans for compensation in the lower Detroit River.

Q. That in deepening, the cross sectional area is to be diminished?

A. To get an effective compensation.

Q. And that is done by piling up the excavated material in a way which diminishes the size of the cross section?

A. Cuts off part of the cross section that compensates the new cut, by that additional 40 per cent, or whatever may be needed to take care of it.

Mr. Williams: Assume in the previous hypothetical question that everything was filled in except the artificial channel, 300 feet at the top and 240 feet at the bottom, all the shallow part was filled so that the cross sectional area of the new channel would be considerably less than the total cross sectional area of the original channel. What would you say in that case as to the amount of water that would flow through the new channel as compared with the old, assuming the same slope?

A. Without careful computations, I would not care to give an answer to that question. The general proposition that in compensating you need to cut off more area of shallow water than the increased area in a compact section is well established; there is no question about that. And in discussing the working up of the method of this compensation in the lower Detroit River, that is taken into consideration; the form of the section, as to whether it was compact, and the form of the shallower section which has to be cut off to compensate it.

Q. In order to render the compensation complete, the cross sectional area in the new channel in the Detroit River will be less than the cross sectional area of the river at that point?

A. Yes.

Q. I will ask you, after having propounded this hypothetical question to you, whether or not the case presented by the question that I asked you does not fairly illustrate the con-

ditions of the connecting waters of the great lakes as they stand, without the improvements? In other words, isn't the problem which I have suggested a fair statement of the situation as it exists?

A. No, for the reason that other matters have come in that enter into the case. I have discussed them somewhat in my report on the preservation of Niagara Falls, on the Niagara River there. And there the narrowing of the river in places, the extension of docks out from the original shore line has a tendency to cut off part of the cross sectional area. At Tonawanda on the Niagara River, for instance, an encroachment has been made; dredged material is as a rule dumped in the river itself and has a compensating effect. In the Detroit River for instance, the advance of the dock line has narrowed the river along the Detroit front; and it is true on the Canadian side as well; and the tendency is encroachment, in a good many cases they compensate.

Q. But you cannot any more than fill up the shallow parts of the river with this excavated material?

A. There is no excavated material opposite Detroit, but the dock line has been advanced and cut off the river.

Q. The docks cannot extend further than the line of navigation?

A. The harbor line is the limit of the docks; that is established by the War Department. I might say that on Lake Ontario an improvement, if it may be considered such, the Gut dam, to which our government consented and is therefore a party to, raised the elevation of the St. Lawrence River and Lake Ontario four to five inches, as I have previously testified.

Q. What was the amount of head figured by you in estimating the water power at Niagara, at these power plants?

A. 220 feet; that is at the cataract and the rapids above the cataract.

Q. And you figured the entire fall from what point?

A. From the intake of the Niagara Falls Power Company to the portal, which is the outlet of the same company.

Q. Are there any losses in the head or in the tail race?

A. I took account of those in the 80 per cent. I made a reduction of 20 per cent for loss.

Q. You mean that your estimate of 25-horse power per cubic foot was theoretical horse power?

A. Theoretical, on the head of 220 feet. It is 220 divided by 8.8.

Q. And then your loss of 20 per cent in the actual is what you allowed for the loss in head and tail races?

A. Yes.

Q. What degree of efficiency do you figure then in the wheels?

A. Perhaps 84 or 85. For those wheels on the high heads, I understand the efficiency is very high. Higher than the ordinary turbines.

Q. 84 or 85, if you allowed for efficiency 85 per cent, that would only leave 5 per cent that would have been lost by reason of head and tail races?

A. That is something over ten feet; the actual head under which the Niagara Falls Hydraulic Company is operating is about 210 feet. That is between head water and tail water.

Q. Is this head you are testifying about on the American or Canadian side?

A. That is on the American side.

Q. You were asked by Mr. Wilkerson with reference to diversions at Niagara, and the effect of those diversions, if any, upon the level of Lake Erie. What diversions did you have in mind?

A. The diversions of the Niagara Falls Power Company; the Niagara Falls Hydraulic Power & Manufacturing Company, and the Ontario Company on the Canadian side.

Q. How many cubic feet per second would you say is involved in those relations?

A. Something less than 20,000.

Q. 220,000 cubic feet per second?

A. Per second, yes; that is there is not that much in use at the present time. Perhaps 15,000 cubic feet per second would be a closer estimate.

Q. Now what were the compensating influences that caused those diversions to fail to influence the level?

A. Why I should state in this connection that our earlier measurements of the river were made in 1898, when about half the present diversion of the Niagara Falls Power Company was in effect, and the added diversions since that time—I am speaking very roundly now—may be eight or ten thousand cubic feet per second. I think perhaps I have not stated that correctly. The effect of a diversion of about 11,000 cubic feet above the rapids there would lower Lake Erie about half an inch, 5/100, and during certain years, 1904 and 1905, the divertors of the Ontario Company were in place, and those backed the river up, so that there was a rise of something

like four inches in the river above the rapids there at Niagara Falls, and that would temporarily give Lake Erie a tendency to rise, but the rise would be very small; it would be 3/16 of four inches.

WILLIAM LIVINGSTON, a witness recalled for further cross-examination by Mr. Williams, testified as follows:

Q. Mr. Livingston, one of the questions that was asked you, which you said you would look up was with reference to the percentage of boats that would be affected by a diminution of draft of two inches, boats that ply in the northern lakes, and in the harbors of Lake Michigan, that do not pass through the St. Clair and Detroit Rivers?

A. That do not pass through?

Q. Yes.

A. I cannot give it to you. I have sent for the information but I have not obtained it. I want with your permission to correct one statement I made the last time I was in. I said that the average cost per day for the running expenses of a boat was $160. That of course was exclusive of loading and unloading; I am just talking about the operating expenses of a boat independent of that. It would be $160 a day including insurance. I started to get these matters in motion and I had to send over to get some data that I didn't have in the office, and I got to figuring over and looking over some statements which I have, and I would like to correct that. I think I made that too low; I think I should have made that $180 a day. I find there are two or three things I neglected to take into consideration. We always increase the wages of our employes, for instance, the first of October, increase them ten dollars and so on, depending on the positions they are in. And there are a number of other matters, and I find a difference too in many of our fleets in the way of computing expenses; the system of bookkeeping is a little different, so I am satisfied now, after spending a little time, that for that class of boats, 10,000 tons, I should have said $180 a day to have been safe. I would like to correct that. Ordinary maintenance and upkeep such as painting and minor repairs are included in the $180 per day; that also covers insurance.

Detroit, Michigan, June 4, 1909, 10 A. M.

Parties met pursuant to notice.

F. C. SHENEHON, resumed the stand for further cross-examination by Mr. Williams and testified as follows:

Q. You have charge, Mr. Shenehon, of the publication of charts showing the channels through the Great Lakes and connecting waters?

A. The Lake Survey issues those charts.

Q. And they are under your direction?

A. Under the direction of the officer of the Lake Survey. I understand you mean finished charts that were published?

Q. Yes.

A. The Principal Civilian Engineer, which is my title, has more direct charge of the field process, although as First Assistant to the officer in charge, he has an indirect charge of the whole office. But my supervision over the actual publication of the charts is rather small.

Q. Can you furnish us charts from which can be obtained cross sections of the Detroit River at the Lime Kiln Crossing?

A. The chart of the Detroit River will give that, but not with a high degree of precision.

Q. Within what degree of precision would you say the chart would give that cross section of area?

A. I should say within 5 per cent.

Q. Have you one of those charts available?

(Witness produced a chart which was marked for identification "Defendant's Exhibit A, June 4, 1909"; the same being a chart of the Detroit River projected from a trigonometrical survey issued under the direction of Major C. B. Comstock, of the Corps of Engineers, Brigadier General U. S. A., in 1873. Additions and corrections under the direction of Major W. L. Fisk, Corps of Engineers, U. S. Army, in 1902-4, and Colonel G. J. Lydecker, Corps of Engineers U. S. Army, 1905-6, and Major Charles Keller, Corps of Engineers, 1907-9.)

The Witness: I should like to change that precision to 10 per cent. I figured on about one foot of allowance there, and I see there is only about ten feet of water in place; 5 to 10 per cent, make that.

Q. Would you say that it was precise within one foot; that was the basis of the estimate?

A. Yes, I should say it was closer than that.

Q. By referring to that chart, can you readily give us the original depth along the section of the Detroit River in the Lime Kiln, or if you have other sources of information from which you can give the information, let us have them.

A. This shows the condition of the river on March 20, 1909, not in its original condition.

Q. Do you know, Mr. Shenehon, what the depth originally was along that section?

A. No, I do not.

Q. Can you state what the widths and depths of the channels through that section are, at the present time?

Mr. Wilkerson: You mean the dimensions before any improvements were made at all?

Mr. Williams: That was the other question, but he says he cannot give that. Now I ask for the width and depth of the present channel.

A. The width of channel given is scaled from the chart and shows for the Lime Kiln 600 feet.

Q. Six hundred feet in width?

A. Six hundred feet in width, yes; with a depth of twenty-one feet when Lake Erie is at elevation 571, by the levels of 1903.

Q. Have you in your custody or in your office surveys or charts or any other sources of information from which you could give us the original depth of the channel at that point?

A. I think so. I will have to have them looked up.

Q. What is the total width of the river at that point, the width of that section rather?

A. About 8600 feet.

Q. Is there a current over the entire width?

A. I think so.

Mr. Wilkerson: You are now speaking of the Lime Kiln crossing?

Mr. Williams: Yes, the section of the Detroit River at that point.

Q. Does Stony Island have any effect upon the current in that section?

A. Stony Island is above the section I measured, and in the wake of Stony Island, below Stony Island there should be dead water for a certain distance.

Q. At the point where you measured, you will say there is a current across the entire channel?

A. The section measured is about 2100 feet below Stony Island, and I should say there was current in every portion of that.

Q. In giving your answer as to the width of the present channels, 600 feet, did you include the Livingstone channel in that statement?

A. No.

Q. I believe you testified to it before, but so that we can get it all together, will you now state the dimensions of the Livingstone channel now in course of construction?

A. Three hundred feet in width at that point of the river, and 22 feet deep below Lake Erie elevation 571.

Q. Can you give the dimensions of the channels that are cut off by the cofferdam, which is shown on the chart?

A. The cofferdam from the east point of Stony Island extends eastward about 1400 feet, and the completed portion extends down stream about half a mile. The old pier of the Michigan Central Railroad, which coincides with the upper end of the cofferdam, had an original length of 1200 feet.

Q. What is the width of the channel at the upper end of the cofferdam; the entire river? The cofferdam is not situated at the point where you made the measurements of a few moments ago?

A. No, about 3200 feet above the section measured.

Q. At that point its width is what?

A. At that point the river width is about 3500 feet east of Stony Island and 1100 feet west of Stony Island.

Q. Can you give us the depth of water along the upper end of the cofferdam?

A. From five to fifteen feet.

Q. That is shown on the chart?

A. The nearest soundings indicated are five, six, ten and fifteen.

Q. What is the most accurate method of measuring water, Mr. Shenehon?

A. Such rivers as we have under consideration, the current meter method.

Q. Without reference to the rivers we have under consideration, what would you say was the most accurate method of measuring water? Isn't it by weight, the most accurate method?

A. By weight, yes.

Q. And next to that what would you say was the most accurate?

A. By volume, the size of the vessel containing it.

Q. And the next to that?

A. Current meters.

Q. What would you say as to the degree of accuracy that may be reached in the measuring of water by means of a weir as compared with current meters?

A. I should say the current meter method is as accurate.

Q. Is as accurate?

A. Is as accurate, yes.

Q. Would you say it was more accurate?

A. Very inaccurate work can be done with a weir.

Q. Assume the same degree of skill exercised in measuring with a weir as would be exercised in measuring with a current meter?

A. I am not familiar with weir measurements by having made any personally. I have a very general knowledge of the subject, and the exact degree of precision I am not prepared to state.

Q. In making your gaugings with a meter, you seek to get the meter in the same vertical section at each gauging?

A. That is at the same station, as we call it; it is the same vertical line; when I say the same, within a few feet of the same.

Q. You make an effort to get it as near the same as possible?

A. Within the limits we regard as required by the accuracy, yes.

Q. How close would you say you are able to do it?

A. Oh, four or five feet, or less.

Q. Are the velocities in a flowing stream uniform from one point to another?

A. No. Let me understand what you mean. You mean do they vary in uniformity from one point to another by regular gradations. What is the meaning of your question?

Q. I mean are they uniform; is there any law so that you can tell from the gauging at one point exactly what the velocity is at another point some feet distant from that?

A. Taking a station well out in the stream, of one of the sections that we have used in the Lake Survey measurements, the velocity four or five feet away from a particular station is very well known; the variation is sufficiently uniform so that we do know.

Q. Is it absolutely uniform?

A. I should say not.

Q. It would be practically impossible, would it not, to observe the velocity of a stream at every point?

A. Yes.

Q. Assume a circular pipe of a uniform diameter, and flowing water through it, what would you say as to the uniformity of flow through a river as compared with the uniformity of flow through that kind of a channel, opening?

A. I should say the uniformity through the river was very much higher, through such sections as we have used in our gauging.

Q. I call your attention, Mr. Shenehon, to page 5369 of Appendices III and KKK of the Annual Report of the Chief of Engineers for 1900, and particularly to this sentence appearing in the middle of the page: "The fluctuations in current velocity have usually rendered the determination of the distribution of the velocities in the vertical plane a difficult matter, for if the meter were left at one depth long enough to eliminate the effect of the short, wave-like fluctuations or pulsations of the current, a more permanent change might take place affecting the mean velocity at the station before all of the depths had been covered by the meter." Do you endorse that statement?

Mr. Wilkerson: This is from Mr. Sabin's report.

A. As I understand that statement, Mr. Sabin has reference to the older method of current meter measurements, in which you used a single meter; getting your vertical curve by starting at the surface, or a short distance below it and observing a certain definite time at each tenth of depth. The use of the multiple set, of which Mr. Sabin speaks, and the use of the two meter system that I have used myself, is intended to eliminate all possible sources of error or difficulties of which Mr. Sabin speaks. The water does come in pulsations to some small extent, and the more permanent change he speaks of, I take to mean a change coming with change of gauge.

Mr. Wilkerson: Did you read that sentence about the overcoming of the difficulty? I wish you would read that sentence so that we will have it all in the record.

Mr. Williams: The latter part of the sentence is as follows: "This difficulty is overcome by the use of the multiple meter set, with which the whole vertical curve is determined at one observation."

Mr. Wilkerson: That is the explanation that you referred to in your answer, is it?

A. Yes.

Mr. Williams: You endorse the statement then?

A. I state that the velocities in a river at a given point are fluctuating from minute to minute, and that a change of velocity does come with a change in the lake stage.

Q. And also that there may be certain pulsations that are not permanent in their character and not depending on lake stage, is that true?

A. Yes, if two observations were made, covering ten seconds, they would not closely agree.

Q. And the advantage of having this multiple meter set, which is mentioned in this paragraph, is in effect that the measurement is made at the several points simultaneously, so that anything that affects the meter at a given point would affect all the others at the same time?

A. That is the intention of the multiple meter set, yes.

Q. If that is an advantageous arrangement in the measurement of current velocity, what would you say as to the necessity for some arrangement being made by which the same degree of precision could be obtained by having horizontal measurements made simultaneously?

A. I think the gain to be made by the multiple meter set is one of time-saving rather than ultimate precision. I think just as high precision is gotten by two meters, as I myself have used them on the Niagara River and the St. Lawrence River.

Q. The purport of this report is that the multiple meter set was used for the purpose of curing the inaccuracies that might result from allowing the meter to be left at one depth long enough to eliminate these temporary effects, was it not?

A. The temporary effects that you speak of *are* temporary. The average relation in velocity between two points is fixed very decidedly. The only point is, how are you going to establish that relation, whether simultaneously by multiple meter sets, consisting of a number of meters, by two meters, or by a single meter that by a great many repetitions gets the average percentage relations in the curve. The *facility* of the operation is involved in the use of either two meters or a multiple meter set.

Q. And is not the accuracy of the observations also involved?

A. I do not think the accuracy obtained by the multiple

meter set is greater than the accuracy obtained by two meters.

Q. Is it greater than that obtained by one meter?

A. I think so, although a very large number of observations in the vertical with a single meter does give good results.

Q. Over what percentage of the area of a cross-section is the velocity actually measured in gauging?

A. Perhaps over 25 per cent.

Q. The same observation?

A. Perhaps I misunderstand your question.

Q. With a single gauging, you say that 25 per cent. of the entire area of the cross-section is actually measured.

A. I do not get the trend of your question. I do not know what you are getting at.

Q. Take the area of the cross-section occupied by the meter during a single observation on the St. Clair River.

A. That is a single discharge measurement?

Q. Single gauging?

A. Yes.

Q. The wheel has a certain diameter, and a certain area, hasn't it?

A. Yes.

Q. You observe at a certain number of points a single gauging?

A. Yes.

Q. Now what is the percentage of the actual cross-sectional area of a river covered by any single gauging; take the St. Clair River, for instance, as an illustration?

A. I should say about one-sixtieth of one per cent.

Q. I call your attention to Plate 12, following page 5400 of the report of the Chief of Engineers for 1900, Appendices III and KKK.

Mr. Wilkerson: Is it Plate 12 in connection with Mr. Sabin's report?

Mr. Williams: Yes.

Q. Will you explain that plate? Tell us just exactly what it means?

A. Figure I of this plate is a cross-section of the St. Clair River at Section Dry Dock, showing the bottom profile of the river, the water surface, of current meter stations 1 to 21; and velocities at or near percentage depths; that is close to the surface, close to the bottom and at each of the tenths of depth. These velocities are established by twelve discharge measurements, Nos. 49 to 60 inclusive. Using these velocities, contour

lines are drawn in, which are intended to show the lines of equal velocities.

Q. Each of the lines shown upon Figure I indicates a certain degree of velocity?

A. Commencing with the line at Station 6, that shows the location of the velocities having 3.4 feet per second. The next one to the right shows 3.6; the next one 3.8; the next one 4.0; the next one 4.2; and the small figure under Stations 13 and 14, 4.4. The lines to the left of Station 6, one line is the mean velocity that is a little heavier line than the others. And I think the lines differ by changes of .2 of a foot per second beyond.

Q. These stations numbered from 1 to 21 are a hundred feet apart?

A. I believe so. I should state in connection with this plate that it is my belief that it is the intention to give the velocities only in a general way, to show the distribution over the section; that the precision of the thing as it stands is not very high. It is made up from twelve discharges only.

Q. What degree of precision would you give this plate?

A. I could not make any statement on that point.

Q. What degree of precision would you say it would be possible to get in the drawing of a plate of this character?

A. What do you mean by precision?

Q. How accurately would it be possible to have a plate prepared, so that the lines drawn on it would represent the actual situation as to velocities?

A. Very close to one per cent.; and when I say that, I mean that instead of velocities being set down, the percentage relations of the velocities be set down The velocities indicated there are for twelve discharges.

Q. How many discharges would you say it would be necessary to have in order to prepare a plate to be of the accuracy that you have indicated?

A. The precision would depend more upon the co-efficient work than upon the discharge measurements.

Q. Then you would say that twelve observations would be sufficient?

A. I should say that twelve determinations of percentage relation between the index and any other point would give a very good determination of it.

Q. Will you explain what you mean by co-efficient work?

A. Co-efficient work is to establish the percentage relation between the velocity which measures by the meter at the sta-

tion index, (a particular depth as .3 or .4 depth in the river) and the velocities at other points. The object of co-efficient work is to establish a multiplier or co-efficient by which the velocity at the *index*, at a single station, is multiplied to get the mean velocity in that station. When I say "station" in the second case I mean in that 100-foot width of the river.

Q. Can you explain a little more in detail how you arrive at this multiplier that you have just mentioned? The actual observations occupied, as you say, about one-sixtieth of one per cent. of the entire area of the river being measured, cross-sectional area. How do you arrive at the velocities at the other points?

A. The process of river measurement is a sampling process. When I speak of the measurements in a river occupying a sixtieth of one per cent., I mean samples of the velocity taken cover that part of the area. A bridge engineer in building a steel bridge, I do not imagine takes more samples than one-sixtieth of one per cent. of the weight of the structure; probably less. Sampling of various kind, for wheat, and other things, I do not imagine takes more material.

Q. When you take that much of the material, what do you know about the rest?

A. When you take the measurement in the river, you know by a great many observations in support of that knowledge that the percentage relations is obtained. I will read certain testimony on that line if it is desirable.

Mr. Wilkerson: That is, you have a statement that will explain that.

The Witness: Showing the relations.

Mr. Wilkerson: Do you want that?

Mr. Williams: We are entirely willing. We want all the information we can obtain.

Mr. Wilkerson: I suggest if he has it in well worked out form, it would be perhaps better than the off-hand statement.

Mr. Williams: Now you may proceed. Give us the reference.

A. This is in the report of the Chief of Engineers for 1900, page 5343, and begins: "It has been demonstrated in river hydraulics that the velocities throughout a certain area maintain definite percentage relations, and when these relations are firmly established by ample observations, a single known velocity is the key to all others simultaneously existing, and hence to the discharge in the area involved. On this characteristic of river flow are based the methods used to determine the

volume of water which the river carries in its various stages and conditions. Like most hydraulic laws, this has its limitations and is more nearly absolute as the area considered approaches an element of river width. How accurate it is for the full river width is shown by the following tabulation, in which the mean velocities for each station derived from groups of discharge measurements are expressed as percentages of the mean velocity of all stations for the same group." And the table which follows is headed: "Open Section, Table 5, index velocities as percentages of mean index velocity. Now in this table, the velocities shown by groups—

Mr. Wilkerson: Q. What you have said heretofore is quoted?

A. Yes.

Q. Now you are testifying.

A. Yes, I am just talking. In this table the velocities shown by groups of *ten* discharge measurements are expressed for each station in the form of percentages of the mean index velocity, except that group No. 6, has *seven* discharge measurements in it. As an illustration of the precision with which the percentage relation is maintained, I take at random Station 9. The first group shows the velocity there to have a percentage of 118.2 of the mean velocity; the second group 121.1; the third group 120.5; the fourth group 121.4; the fifth group 121.6; the sixth group 122.1; and the mean of the whole is 120.7.

Mr. Williams: Q. Take Station 1, Mr. Shenehon.

A. Station 1 has a large variation and cuts very little figure in the discharge of the river. I took Section 9 because that carries a high percentage of the flow, and for a second reason because the mid river stations are less variable than those close to the shore.

Mr. Wilkerson: One is a station that is near the shore is it?

A. Yes, that is close to shore.

Q. How far from the shore?

A. Where the area change is fairly large at different lake stages.

Q. Just what percentage of the total flow passes through one?

A. It is less than one per cent., as I recollect it.

Mr. Williams: Q. Will you take Section 8, Mr. Shenehon, as shown by that table, that index?

A. Station 8 shows for the first group 121.3; second, 122.9;

third 124.6; fourth 124.9; fifth 124.5; sixth 123.3; mean 123.6.

Q. Will you look at plate No. 7, following page 5360 of the report of the Chief of Engineers for 1900 and explain the curve shown on that plate for Station 8?

Mr. Wilkerson: The cross-examination of the witness is, I assume, proceeding on the theory that the plates and protions of the reports referred to will be afterwards put in evidence by the defendant. That is correct, is it not?

Mr. Williams: Yes. We now ask to have this Plate No. 7 marked for identification as "Defendant's Exhibit C, June 4, 1909, cross-examination of Mr. Shenehon." Plate 12, following page 5400 of report of 1900 will be identified as "Defendant's Exhibit B, Shenehon's cross-examination."

Q. (Last question read as follows: "Will you look at Plate No. 7, following page 5360 of the report of the Chief of Engineers for 1900 and explain the curve shown on that plate for Station 8.")

A. Station 8 is marked at the bottom of the curve I am explaining. This shows the velocity at that particular station on the Open Section of the Niagara River, or rather the percentage velocity with respect to the velocity at the *index,* which is always 100 per cent. These percentage velocities are platted on the horizontal scale (in a system of rectangular co-ordinates), and the river depths expressed in elevations are shown in the vertical scale. Using this series of heights above the bottom, or elevations, and the percentage velocities, the observations are platted, as shown along the curved line. Those that are platted in solid black circles at the *sub-surface,* the index and the .8 depth and the bottom observations (except for the index always 100), were derived from discharge measurements in addition to the other co-efficient work. That is in measuring a discharge of the river, a current meter was run at the index depth, which is 4/10, roundly, of the river depth at a particular station. The second meter is run at the sub-surface for two minutes, then the second meter is dropped down alongside of the index meter and run for two minutes more. Then it is dropped down to the .8 depth and run for two minutes more, and on a part of the observations it is run down to what is called the bottom observation and run for two minutes more. So each discharge observation, in addition to giving the absolute velocity at the index gives also the percentage relations from surface to bottom throughout the vertical. And as I have already testified, the velocity relationship betwen the stations gives the trans-

verse curve. The observations shown by open circles were derived from special observations, made specifically as co-efficient work. After platting these observations, the curved line is drawn in as a fair line, and it is made to thread, or pass through, the sub-surface, index, .8 and bottom observation.

Q. In doing that, there are a number of points that were determined by several observations that are not touched by the curved line.

A. It is assumed that the law of gravitation under which the river is flowing will be expressed by a fair curve, for the vertical curve; and where we have but two observations as at elevation 547, to pass the curve through that would make a wavering line instead of a fair curve. The weight of the two observations does not warrant that. I wish to say, however, that if a line were drawn that did thread every observation in that curve and that of Station 6 on the same plate, that the results so far as the river discharge is concerned, would be the same; there would be no sustantial change.

Q. But as a matter of fact the observations at point 547, 545, 542, 537, were practically not considered in the drawing of the line?

A. The line was drawn for the most part so as to thread the obseravtions. When I say that, for instance take the observation at 545 and that at 547, the line is drawn between them. And the line cuts a point that might be a mean between those observations, in elevation as well as in velocity, percentage of velocity.

Q. As a matter of fact the line could just as well have been drawn from these index points to .8 depth, from that point on to bottom observation, without any reference to the observations of the points mentioned?

A. No, that is not so.

Q. Suppose that observations at 547, 545 and 542 were all eliminated from consideration; that you were drawing a curve that would pass through the observation of the sub-surface, the index, at .8 depth and bottom, what difference would there be in the shape of the curve?

A. That was 537, was it, Mr. Williams?

Q. Leave out 537, 542; the points determined by four observations there. Leave out 545, the point determined by six observations and 547, the point determined by two observations, eliminate all those, what would be the difference if any in the direction of the line? Eliminate everything between the index and the bottom observation.

A. The observations at 545 and at 547 have been given weight in drawing the line. You notice the line hugs the observation of 6 rather than it does the 2; perhaps I ought to reverse that and say the observation hugs the line a little more closely; the six observations having greater weight, it brings it closer to the line. The observation at 542 and that at 537 do not seem to have swerved the line largely.

Q. If the line passes through the observation at point 543, which is determined by six observations, and passes through the index point and the .8 depth point, how could you very well vary the direction of the line, even eliminating the points at 545 and 547?

A. Whether the observations at 545 and 547 were present or absent makes very little difference in the trend of the line at that point. The observations are confirmatory of the general trend of the line, as they stand.

Q. Would it not be a fairer indication of the actual result of the observation to have drawn your line so as to pass through the point determined at 545 as the result of six observations than to pass by that point and to pass through the points at 548 and 552, which were the result of only two observations each?

A. The object of drawing the line ought to be very clearly kept in mind. We are endeavoring to get the mean percentage velocity ordinate, and whether or not we draw a mean line between two observations or whether we waver the line and thread the particular observations, the result is the same substantially.

Q. Would your contour lines on a map or plate showing the cross sectional area be the same if the line were drawn through point 545 as it is drawn in the direction in which we find it? Wouldn't that make a difference in our contour chart?

A. If the line which we call the vertical curve were drawn so as to pass through 6 at 543 and also through the 6 at 545; through the 2 at 547, joining the line at the 2 at 549 again, the mean ordinate, which is what we are after, would be substantially the same. There would be substantially no effect on the discharge of the river.

Q. Now there is a variation in the velocity of this particular Station 8 within distances of two and three feet, isn't there?

A. In the vertical?

Q. Yes.

A. Very distinct towards the bottom, yes.

Q. That being true, what means of information have you, what knowledge have you as to what the variation may be between this vertical and the next one which is a hundred feet distant?

A. The general form taken by the vertical curve is such that we feel full confidence in view of the corroboration of results and extended river experience, that in midstream we may safely extend the coefficient.

Q. A distance of a hundred feet?

A. For a distance of 50 feet each side of our section. To illustrate that, let me look up the coefficients. I do not find that the coefficients are given for the Open Section, but for the St. Lawrence beginning with Station 4, we have a coefficiency of—

Q. What is the reference there?

A. This is the report of 1902, page 2803. This is my report on the St. Lawrence River, and I am reading from Table No. 19; beginning with Station 1, 88.8 per cent; Station 2, 90.8; Station 3, 88.5; Station 4, 85.6; Station 5, 87.7; Station 6, 89.5; Station 7, 90.7; Station 8, 94.8; Station 9, 94.1; Station 10, 92; Station 11, 92.2; Station 12, 90.5; Station 13, 89.9; Station 14, 92; Station 15, 92.7; Station 16, 91; Station 17, 92.7. The weighted mean is 89.8. Now, if these vertical coefficients, which represent the mean ordinate of this curve, if they vary very slightly from one station to another, even though they form a curve which is slightly different, the result would be no different in the volume of discharge. After a very considerable experience in river measurements, I have the utmost confidence in the continuity of changes of velocity in a river.

Q. And in their uniformity?

A. And in the uniformity, where we would expect it, as in midstream, or in the open part of an open river. Towards shore we do get eccentric conditions, but these by extra observations are considered. The shore end stations of a discharge section in a river carry but one to two per cent ordinarily of the volume of flow; and if in these stations we have an error as large as 10 per cent, the error of the whole volume of the discharge is only one to two-tenths of one per cent, which is insignificant. The big volume of flow is carried in the mid-river sections.

Q. You have finished your answer, have you?

A. I have found something I was looking for; that is the

mean velocity coefficients in the Open Section, that perhaps I had better read, as more pertinent than those in the St. Lawrence previously quoted.

Q. The reference is what?

A. This is page 5347 of the report of 1900. It is a tabulation headed "Open Section, Mean Velocity Coefficients." The depth on Station 1 of the Open Section is so small that velocity coefficients in the vertical are not given. I will give these for elevation 567: Station 2 is 92.8; Station 3, 92; Station 4, 92.5; Station 5, 92.6; Station 6, 92.6; Station 7, 92.6; Station 8, 93.2; Station 9, 92; Station 10, 89.9; Station 11, 89.5; Station 12, 91.2; Station 13, 92.9; Station 14, 91.2; Station 15, 90.6; Station 16, 91.1; Station 17, which is in extremely shallow water and which does not give a fair value for the coefficient is 84.8. That last explanation is not quite correct; I should have stated that for Station 17 it includes the transverse coefficient as well as the depth of water. These are the *mean velocity coefficients* including transverse as well as vertical. An examination of the coefficients derived by Sabin for the St. Clair River will show very close corroborations of these.

Q. I understand that these are the factors by which you multiply the velocity found at the index point?

A. Yes, multiply the velocity shown by a discharge measurement at the index point by the mean velocity coefficient, and that by the cross sectional area; that gives the discharge.

Q. And your judgment is that the mean velocity shown at the index point on one vertical and the velocity shown at the index point on another vertical a hundred feet distant indicates the velocity for the entire 100 feet between the two?

A. No, that is not quite accurate.

Q. Well, state what the fact is with reference to that?

A. From the shore out as far as the indications warrant, a transverse curve is taken; that is the velocity is taken every ten feet, and the relation of the velocity to that the index point for the .4 depth, every 10 feet is taken. As soon as the open river is reached, where the sweep of the transverse curve is broad, these observations are not always taken. I believe they always were in the St. Clair River, but not in the St. Lawrence, and not in the Open Section of the Niagara River. The transverse curve is taken from the fair curve line joining the velocities at the index, as derived from the discharge measurements. That will show you a number of percentages,

showing the relation. Then platting those and drawing a line through them gives the transverse curve.

Q. As a matter of fact you have no information as to the velocities between your verticals except such as you get by the drawing of the transverse curve?

A. That is true in the Open Section of the Niagara River, except towards the end, towards the shore—

Q. Towards the shore ends?

A. And the same in the St. Lawrence River except towards the shore ends.

Q. And in those points there is considerable variation?

A. In the International Bridge Section of the Niagara River, the transverse curve is very accurately determined, on account of the bridge piers and the nature of the bottom there. It was accurately determined for as often as every twenty feet, and towards the piers more frequently, ten or five in some cases.

Q. And how accurately was it determined on the St. Clair River?

A. It is my belief it was taken every ten feet all the way across the river. I am not positive of that, but that is my belief, in the measurements made by Sabin.

Q. How many points in the cross section were actually measured in the Niagara River at the Open Section?

A. In Stations 1, 2, 3, and 17, that is about 200 feet at each end of the river, the transverse curve was measured and used in coefficient reductions. At distances of 33⅓ feet some observations were made for the transverse curve, and these were made by having a single meter at the index point and a second meter 33⅓ feet away on overhangs on a catamaran at the *sub-station point;* but in the reduction, those observations were not used. I would like to state the reason why they were not used, as set down in the report here.

Q. What page?

A. Page 5353 of the report of 1900. "In getting out coefficients, however, these substation verticals were not utilized for two reasons: first, the fixed point in the station verticals" (those are the ones marked in solid black circles on the Plate No. 7) "made their weight so great in comparison with those of the sub-stations," (the sub-stations means the 33⅓ foot points) "that it was difficult to arrive at a rational scheme of combining them. Second, the absence of current ratings as a basis for correcting the ratios made the indications of a compound instrument somewhat unreliable, so that the danger

of introducing an error seemed greater than the possibility of error from neglecting in midriver the transverse curve between stations."

In Plate No. 7, the fixed point shown by the solid black circles at the .8 depths as determined by 45 observations and at the sub-surface by 21, the bottom observations by 17,—those points were so thoroughly well established that it seemed a dilution of the accuracy of the work to attempt to introduce the transverse coefficient.

Q. Can you explain a little more fully what this difficulty seemed to be that you had in combining the observations?

A. Unless we took an equal number of observations on these intermediates, these 33⅓ foot points, the computation of the coefficient would mean the weighting of the several observations; and when I say weighting I mean, if we have a quantity measured a hundred times and we are combining that measurement with a quantity measured ten times, that former measurement having a hundred observations would have a greater weight, other things being equal, than the other.

Q. Before we get to that, is it not a fact that the reason these were discarded and not used, the first reason was that if you followed those observations you would get a different result from that which is obtained in your more reliable and greater number of observations at the index point?

A. As regards the discharge of the river, I do not know that that is the fact.

Q. Would you be able to offer any other explanation why there was difficulty in combining those observations with these non-reliable ones that you do rely on?

A. Perhaps I would better go on with the second statement, then we can talk of the whole thing together. It was found in the use of the two meters that there were slight divergences from day to day for the ratings, and the apparatus we had for observing these intermediate verticals made it difficult for us to compare one meter with another. The integrity of the two meter system depends on the fact that you combine the two meters by running them side by side in the current, and rate one with respect to the other for each day of your current work. And the apparatus for getting these 33⅓ foot points was so cumbersome that it was not easy, and was not done, as I recollect it. It was estimated that the possibility of getting an error of two per cent in these intermediate verticals was likely to give us an error

in the result greater than by not introducing the transverse curve. I have spoken of that as likely; I do not know as a matter of fact whether it would have changed the result one way or another. I was steering clear of the possibility of error and believe, now, that I chose wisely.

Q. You speak of the possibility of the meters used in these 33 foot points being likely to vary from day to day or during the same day in their rating?

A. Yes, there might be a variation the same day, possibly as much as one per cent, and from day to day there may be as much variation as two per cent.

Q. And the only reason that you have for believing that that would not be true where the observations are made at the index points is the fact that you were using two meters, one acting as a check upon the other?

A. In using two current meters in coefficient work, any slight variation as two per cent in the rating in the meter did not make any error in the percentage results because the meters were run in the current side-by-side, and the ratings were interlaced and made common in that way, so that it became a single instrument for coefficient work. When it came to discharge measurements then an error of two per cent in the absolute rating *did* make an error of two per cent in the discharge, and that was taken care of by using a number of meters, and rating them frequently; any error that might come into an individual observation being eliminated in the great multiplicity of observations.

Q. Do you remember the number of points in the cross section of Niagara, the Open Section that were actually measured in making the discharge measurements?

A. Seventeen; there were seventeen stations and a measurement at each of the seventeen stations constituting a river traverse, was a discharge measurement, taken in connection with the gauge readings.

Q. And at the International Bridge how many points were actually measured?

A. Twenty-one.

Q. Will you give us what the cross sectional area of the Niagara River at the Open Section was, also at the Bridge Section?

A. (No answer.) At 567.0 O H levels. Open 42,063 square feet. Bridge 39,335 square feet.

Q. At how many stations were observations made in the St. Lawrence, in making discharge observations?

A. At seventeen stations.

Q. Do you remember how many points in each station observed?

A. As a rule six in each discharge.

Q. And in some instances eleven?

A. At each station? No. The method there was to do the coefficient work at the same time we were making the discharge measurements; that is we had two meters and one would start (on the measurement of the discharge); it would start at the subsurface as zero and go to the 2/10, 4/10, 6/10, 8/10 depths and bottom. On the way back again, or some other discharge, measurements were observed on the odd tenths of depth, so each discharge measurement gave us a full set of vertical curves.

Q. What was the cross sectional area of the St. Lawrence River at the point where discharge measurements were taken?

A. 51,000 square feet roundly. It varied of course with the stage of the river.

Mr. Williams: I would like to have at this point Plate No. 6 marked as "Defendant's Exhibit D, June 4, 1909, Shenehon's cross-examination"; the plate following page 5360 of the Report of the Chief of Engineers for 1900.

Q. Please state the cross sectional area of the Niagara River at the International Bridge, where discharge measurements were taken?

A. At elevation 567.3, that was in levels of 1903, the cross sectional area is about 39,000 square feet.

Q. And the cross sectional area of the Open Section, what was that?

A. For the same elevation, about 42,000 square feet.

Recess to 1:45 p. m.

1:45 p. m., June 4, 1909.

The cross-examination of Mr. SHENEHON was resumed as follows:

Mr. Williams: Q. Have you now, Mr. Shenehon, the data from which you can give us the information asked for with reference to the Detroit River as it was prior to the improvements made by the United States Government?

A. Yes, I think so.

Q. What was the original depth of the Detroit River prior

to the making of improvements by the general government in the stretch from Stony Island to Fort Malden?

A. That is along the channel, along the vessel track?

Q. Yes.

A. Reading the soundings within the channel lines from abreast of Texas Dock downward, down stream for a distance of about 6,000 feet we have: 25 feet, 22 feet, 24 feet, 24 feet, 25 feet, 25 feet, 24½ feet, 22 feet, 24, 21¾, 21¾, 22¼, 22, 22¼, 23½, 22½, 22½, 23½, 24½, 19½, 18½, 18½, 18½, 18½, 20, 18½, 17½, 18½, 14½, 16½, 15½, 15, 15½, 15½, 16½, 17, 19½, 18½, 17½, 16½, 19½, 17¾, 17½, 18½, 19, 18½, 17½, 16½, 19, 18½, 19½, 19½, 20½, 20½, 19½, 22½, 19½, 21½, 22½. That would be about the limit.

Q. To what does that refer?

A. That refers to elevation of Lake Erie 573.2. To compare it with the elevations on this chart, Defendant's Exhibit A, subtract from those depths 2.2 feet.

Q. Subtract from those that you have given?

A. Yes.

Q. Compute for us the discharge capacity of the Detroit River at mean stage of Lake Erie for the reach from the head of Stony Island to Fort Malden as it existed prior to the first improvements and as it will be on completion of the Livingstone channel, assuming the material from the latter work is to be distributed over the area in a reasonable manner.

Mr. Wilkerson: That question propounded to the witness is to be taken by him and answered as opportunity presents itself.

Mr. Williams: Yes, that is right.

Q. You were about to continue, giving the title of the map from which the soundings were taken?

A. The soundings read are from the Lake Survey map or Field Sheet of 1873 U. S. Lake Survey, files 1-550; and the elevation of water surface is referred to Lake Erie 573.2.

Q. Mr. Shenehon, do these tables which I now hand you, or which I have in my hand correctly show the levels of Lake Superior, Michigan, Huron, St. Clair, Erie and Ontario as indicated by the records of your office?

A. They were prepared from the records in this office and I believe correctly represent those records.

Mr. Williams: I will ask to have these papers marked "Defendant's Exhibits D, E, F, G, H, and I" cross-examination of Mr. Shenehon, June 4, 1909.

The Witness: In connection with my answer, my attention has been called to the fact that certain changes have been made on the Milwaukee record due to the settlement of the pier there; and I am not certain whether it is incorporated on this record for Milwaukee or not. It is on the *hydrograph* of one of the prior exhibits showing lake elevation.

Mr. Wilkerson: You say that change was made on the hydrograph?

A. Yes, it is correct here; I am not certain whether it was made on these tables. I believe it was though.

Mr. Williams: Q. That is on Exhibit 5, May 24, 1909, it is correctly shown?

A. That change was only a matter of a few hundredths of a foot.

Q. In the report of the Chief of Engineers for the year 1904, pages 4096 and 4097, appear tables of elevation referring to Lake St. Clair; in which tables there are elevations shown in addition to those indicated upon the sheet known as Defendant's Exhibit G. Now what would you say as to the probable reliability of those tables as showing the elevation of Lake St. Clair?

A. I don't know that these are accurate. I do not know the source of them, as a matter of fact. In the case of the Detroit River and St. Clair River, I believe Mr. Sabin gathered some data from gages outside the office; and I do not know what the reliability of the data is. I have not studied that part of the subject. Prior to, say 1870, possibly extending into the early seventies, there are in some cases doubts as to the elevations; in certain cases I believe after that time, but in the seventies was the time the Lake Survey —it was one of the periods when the Lake Survey was operating largely, and at that time things were established on a firmer basis than they ever had been before, as regards water levels. Prior to that, error may exist in some of the data.

Q. Have you any reason to believe that in these tables, which I have called your attention to, in the report of 1904, there are inaccuracies in the table of elevations for Lake St. Clair to a greater extent than, say, one-tenth of a foot?

A. I do not know. In answering that question I understand you mean the earlier observations?

Q. The earlier observations and those which are not included in this sheet after 1872?

A. In the case of Lake St. Clair, I ought to explain that some observations are interpolated from the Windmill Point

gage. Subsequent to the publication of that 1904 report, precise levels were run from Algonac to the St. Clair Flats. That was last fall and the result of those levels caused a small adjustment in the nominal elevations of Lake St. Clair. What I mean is the mean of the elevation changed by I think .06, somewhere in that neighborhood.

Q. These tables to which I have called attention were prepared in your office, were they not?

A. Yes.

Q. You considered them reliable or you would not have published them, of course?

A. Personally I had nothing to do with the publication.

Q. You made the reports, or worked on them?

A. I was not Principal Assistant Engineer at the time that report was made. I began to be Principal Assistant in 1906. I had nothing to do with the compilation or issuing of that report except my own portion of it.

Q. Will you tell us who would be the proper person to interrogate on the question of the reliability of these tables showing the elevation of Lake St. Clair?

A. Mr. E. E. Haskell, now Dean of the College of Civil Engineering at Cornell University, was the principal Civilian Engineer at that time, and the report itself was made by Assistant Engineer Thomas Russell, who is a member of the Lake Survey at the present time.

Q. Now if these tables which have been marked as Defendant's Exhibits E to I, inclusive, show that the years 1860 to 1865, inclusive, the mean difference of elevation between Lakes Huron and Erie was 8.92 feet, would that be the correct difference, as near as the same could be determined, in your opinion?

A. Is that the mean for the full year or for the open season of navigation?

Q. That is the annual mean.

A. I should say that that mean would be influenced by ice conditions and would not necessarily be the proper relation between Lakes Huron and Lake St. Clair.

Q. This is Lakes Huron and Erie I am speaking of. The question was whether or not, if these tables show that the mean difference of elevation between Lakes Huron and Erie for those five years was 8.92 feet, would that be the correct difference as near as it can be determined?

A. For that time?

Q. For that time, for that period?

A. That is between the Cleveland Gage and the Harbor Beach gage, or Milwaukee?

Q. Milwaukee gage.

A. The Milwaukee gage, for that time; I do not know of any better way of determining the difference in elevation at that time.

Q. And you would answer similarly, with respect to the period from 1866 to 1871. We are assuming that these tables show a difference of 8.68, as the mean difference between Huron and Erie?

A. That is 1866 to 1871. I do not know of any better way of determining the difference.

Q. Would your answer be the same respecting the period from 1872 to 1877 where the mean difference from these tables would appear to be 9.01, as to the correct mean?

A. I assume if the Harbor Beach gage or the gage in that vicinity were available, the results from that should be used, I think, in that determination. That was made about 1874, I think.

Q. Are the observations made at that time included in the tables?

A. For Harbor Beach, yes. Aside from any small correction from that, which would be very small, that 9.01, provided the computation is correctly made, would be the best evidence we have regarding the difference between the lakes.

Q. And for the period from 1878 to 1883, inclusive, using the mean difference of elevation of 8.8 feet?

A. The Harbor Beach gage should be used in that, in conjunction with the Milwaukee?

Q. Yes.

A. Or independent of it?

Q. Which did you mean, in connection with it or independent of it or both?

A. They give practically the same result, so it is rather immaterial, it will not make much difference.

Q. Then that would be the correct difference as near as you can arrive at it?

A. It appears to be, yes.

Q. And for the period from 1884 to 1889, if the mean difference of elevation between these lakes appeared from these tables to be 9.18, would that be correct as near as it can be determined?

A. Yes, I think that is the proper—

Q. For the whole period covered from 1860 to 1889, in-

clusive, the average difference appears to be, from these tables, 8.91 feet. Is that correct?

A. I am assuming the correctness of your computations in this.

Q. Assuming that that computation is correct, and that the computation is based upon these tables, would you say that that was a correct average for those years, or would you say that there was any method of determining that mean difference any more accurately than that?

A. The mathematical process used insured the fact that it is the average, by the definition of average.

Q. Can you give any explanation of the fact that Mr. Wheeler in his testimony gave the average for the period from 1860 to 1880 as 8.52; assuming that our computation is correct? Have you any information as to how he arrived at that conclusion?

A. What do your computations make it for the same period; that is from 1860 to 1880?

Q. The ten-year periods do not end with 1880. Taking it clear to 1889, and the period from 1884 to 1889, which is the highest of any of them, gives it 8.91; taking it up to 1883, it gives 8.8?

A. Well, I do not think the process that you are using is a valid one, of comparing periods other than the same periods Mr. Wheeler used.

Q. Do you know what periods he used?

A. You have just said he used the period from 1860 to 1880. You cannot compare different periods and get the same result, unless the mean elevation of one of the lakes, at least, is the same for the two periods.

Q. These ten-year periods, all of them, show a higher average than the value which Mr. Wheeler got, this group, and it does not seem as though it would be proper to drop in there with something that would give a greater average for those twenty years than that made up of the ten-year period running on through?

A. My own computation for the years 1860 to 1879, both inclusive, gives 8.85. I do not know how Mr. Wheeler got his result; and it is possible that it comes in the old levels, the adjustment. He might have used his own tables in the 1903 report.

Mr. Wilkerson: By that you mean there has been an adjustment in these tables from time to time?

A. Yes, in the adjustment of the levels a certain correc-

tion was applied at Cleveland to bring them up to what we call the levels of 1903, and there was a difference also at Harbor Beach and Milwaukee.

Mr. Williams: Q. Those were taken into consideration in these tables, were they?

A. Yes, those tables are on 1903 levels.

Q. And if these tables show a mean difference from 1890 to 1908 of 8.4 feet, that would be as nearly correct as you can determine it?

A. That is the last period from 1890 on?

Q. 1890 to 1908?

A. Well, I would like to point out that your method of extending your period beyond 1880 to include the high water of 1886, and then in your second period including the low water of 1895, is hardly a fair one.

Mr. Wilkerson: Q. That would explain that difference to a very large extent?

A. Yes.

Mr. Williams: What difference?

Mr. Wilkerson: The 8.8—

Mr. Williams: That was prior to 1880.

The Witness: In high water Lake Huron will go up higher than Lake Erie, so the difference becomes greater as the stage increases. Including that high water of 1886 in your earlier average and including in your later average the low water of 1895, you get the lights and shades contrasted in a way that is not fair. For the 10 years between 1860 and 1879, I get a difference of 8.85; and for the years from 1880, including the year 1908, I get 8.62 as the difference. For the two periods considered, the fall between the lakes is .23 less in the latter period than the earlier one; and just what the stage of Lakes Michigan and Huron was at that time I have not computed. That would have some small bearing on that.

Q. Can you very quickly compute and give us the result of the computation, showing the difference for the period from 1890 to the present time?

A. Yes. 8.41.

Q. Now taking it on this assumption that for thirty years from 1860 to 1889, inclusive, the average fall between Lake Huron and Lake Erie was 8.91; and that for the nineteen years from 1890 to 1908 it was 8.41, to what would you ascribe the change of .51 feet, .5 of a foot, practically six inches?

A. In the earlier of the two periods mentioned, Lakes Michigan and Huron had an elevation of 581.71, and in the

latter period 581.05, as I compute it, making a difference in the stage of Michigan and Huron of .66 of a foot. Now on account of the higher stage of Lakes Michigan and Huron, you would expect the difference on Erie to be 70 per cent of 66, that is the ratio of the movements of the two lakes. You would expect the difference in level between the lakes for those two periods to be 0.46 foot apart, and I think you made it out .50; it checks within half an inch.

Q. Do you mean that if Lakes Huron and Michigan were six inches higher at a certain period than at another period that two-thirds of that excess in elevation would remain as a difference of elevation between the two lakes?

A. I mean to say that if you will plat Lake Erie with respect to Lake Huron you will find out that their elevations vary somewhat in the ratio of 100 to 70 or 100 to 70 per cent. By that I mean if Lake Huron goes up a foot or is a foot higher in any particular period, Lake Erie is .7 of a foot higher at the same time. That is an approximation you understand.

Q. If Lake Huron goes down a foot, what is the effect on Lake Erie?

A. As shown by the gage readings, that relation holds, lake goes down 0.7 foot.

Q. About .7?

A. About .7; or if Lake Erie goes down a certain amount, Lakes Michigan and Huron will go down the reciprocal of 7, which is somewhere in the neighborhood of 40 per cent greater. That is about 43 per cent in excess; and that is one of the reasons that I gave why I considered that the lowering, in the case of Lakes Michigan and Huron by the diversion at Chicago was likely to be in excess of the lowering caused on Erie. I took the case where the increment is most accurate, in the Niagara River, where we have a range of four feet. We find that the lowering is 2¼ inches. And if the lowering of Michigan and Huron is derived by means of that relation, it will be 40 per cent greater on Lakes Michigan and Huron, but that process is rather involved, and hardly defensible, in getting at it in that way.

Q. Mr. Shenehon, diverting from the regular course of procedure outlined, will the effect upon the elevation of Lake Erie be greater or less than that upon the elevation of Lakes Michigan and Huron, assuming that the elevation is changed by reason of the diversion at Chicago?

A. In my evidence on that point I showed the increment

of the Niagara River to be 22,000; and I stated the increment of the St. Clair River was 24,000 with a possible error of 25 per cent, which would reduce it to 19,000 if the full percentage was applied; and that indicates that I consider that the lowering on Lakes Michigan and Huron will be greater than on Lake Erie; I stated between 2 and 2½ inches, and I did not give much weight to that consideration of the relative movement of the two lakes, and yet if you will plat them it is astonishing with what precision in five-year periods the lakes will follow this line.

Q. Assuming that is true, have you any explanation to offer as to why this difference in mean elevations actually occurs?

A. For one period there is a certain mean elevation that is higher than for another period?

Q. Why there is a greater difference in one case than in another. You testify you think it is true?

A. If the increment of the St. Clair River were greater than that of the Niagara River, we would expect the fluctuations in stage at different periods to be greater. In a small pool that is a very clear relation. In the big lakes, the reservoir effect masks it to some considerable extent.

Q. In 1889 it appears that the difference in elevation between Lake Erie and Lake Huron, assuming this (indicating chart) to be correct now, is practically 8.9 feet?

A. Yes.

Q. The next year the difference in elevation is 8.1, or less. Now what I would like to have you do, if you can, is to explain why those variations in difference exist. We can understand the reason why the lake is higher at one time than another and why one lake is lower sometimes than at other times, but why is there the variation in difference of elevation of the two lakes, in so short a period?

A. That is about 0.8 of a foot, is it, the difference?

Q. Yes.

A. The curve of the water level of Lake Erie, as shown on Exhibit 5, shows steadily rising water for Lake Erie, beginning with November, 1889; continuing through the winter and up to June of 1890. The curve of Lake Huron beginning with December, 1889, shows lowering levels, up to March, 1890. The indications are that ice in the St. Clair River did not interfere with the flow of the St. Clair River, but during the winter season it continued to send good volumes of water to Lake Erie. It is possible that ice conditions in the Niagara

River had something to do also with allowing Lake Erie to climb up. Local climatic conditions, as large rainfall on the Lake Erie basin might have entered, while the precipitation on Michigan and Huron basins might have been small. The year selected is, so far as I can see, the most abnormal year since 1875, and the discrepancy of 0.8 between those years is not one that need give us any serious concern. The ice conditions and local rainfall effects may accumulate in one year out of twenty-five or thirty, so that we will get a condition that is as extraordinary as the one you speak of.

Q. Look at the year 1903, would you consider that same explanation as applicable to that year?

A. You mean the year 1901?

Q. 1903?

A. That is 0.4 of a foot difference for that year.

Q. Yes.

A. That is between the year 1903 and 1904 on one side and 1902 on the other.

Q. I understood you to state you considered this an abnormal year. I was only calling attention to the fact—

A. I mean as regards the difference between the two years; this is 0.4. I said it was the most abnormal year—

Q. Take 1901-2?

A. 1901, I have already called attention to in this case as a year of extraordinary ice conditions; and I think perhaps the ice condition will explain most of these differences; that is this large difference. In 1901, my evidence earlier in the case, shows the conditions were very abnormal. Did you want an answer to 1903?

Q. Yes, if you can give it?

A. That 0.4 is probably due to absence of ice effects in 1903, and difference in local precipitation, evaporation, and those elements in the case.

Q. To what would you ascribe the general tendency of a decrease in the difference of elevation between the two lakes, indicated by the fact that the average difference during the past twenty years is approximately 6 inches less than it was during the twenty years preceding?

A. I have already testified along that line.

Q. I did not get the explanation in my mind. I do not know whether it is in the record as to why the general tendency decreased. You gave an explanation of the specific years where there were abnormal years. Now the general

average for the past ten years appears to show a difference of elevation of 6 inches less than the preceding twenty years?

A. In the early period from 1860 to 1889, inclusive, the elevation of Lakes Michigan and Huron was 581.84. In the latter period from 1890 to 1908, inclusive, the elevation was 580.53, a difference of 1.31. Now Lake Erie, we expect to go down 70 per cent of Huron's lowering, which is .92, and the difference between 1.31 and .92 is the increased difference in level you would expect, which is practically 0.39; and I think you stated it to be .5 of a foot.

Mr. Wilkerson: You substitute the figures you give now for the ones you gave a few moments ago, is that right?

A. Yes, if the period is the same.

Mr. Williams: Yes.

Mr. Wilkerson: Assuming the period is the same, this amended computation that has been made here gives the figures more correctly than the other ones?

A. Yes.

Mr. Williams: Q. I understand that when there is a variation in the elevation of Lakes Huron and Michigan of 1.31 feet, or a lowering to that extent, that there is a lowering in Lake Erie of 70 per cent of that amount; and the 70 per cent of that amount deducted from the lowering in Lakes Huron and Michigan accounts for .4 of a foot difference. But what I am trying to get at is, have you an explanation to give why there is 70 per cent of that difference noticeable in Lake Erie, instead of 100 per cent or 120, or any other per cent?

A. That 70 per cent is a very approximate figure.

Q. Why isn't there just as much of an effect in Lake Erie as there is in Lakes Huron and Michigan? Why is it 70 per cent, or any other per cent?

A. It is 70 per cent because the observations show that the thing is running that way.

Q. But do you have any reason for it except that you have noticed that it was a fact?

A. I have stated that the reason I think, the controlling reason, is the fact that the increment in the St. Clair River is really smaller than the increment in the Niagara River. Let me make that clear: in the case of small pools where the reservoir effect does not enter so largely, and we can see the thing very much more clearly, if we know the increments of two pools as for instance the Whirlpool and the pool in the Niagara River above the Rapids, above the cateract; if we

know that the increments are in the ratio of 2.50 to 0.56, we know very well that the fluctuations would bear the inverse ratio. It is not entirely certain that when you take larger reservoirs like Lakes Michigan, Huron and Erie that you can —rather it is very certain that you cannot—argue with the same certainty that you would in the case of these smaller pools. The local supply, local runoff, local evaporation, those elements are likely to enter in, and I do not want to state, on the face of that, clearly that I know the increment in the St. Clair River is smaller than it is in the Niagara River; but I think it is a clear proposition.

Q. Will you state it as your belief that the increment in the St. Clair River is smaller than that of the Niagara River?

A. I have already done that in my evidence, yes. I gave that as one of my reasons why I thought 25 per cent was not an improbable error in the increment as it was set down on the chart, which shows 23,820.

Q. Suppose, Mr. Shenehon, that when an examination of the discharges were made with reference to the lake elevations it were found that for a known elevation of the lake there were two different discharges. Would you account for this as being probably the result of erroneous gage readings, within the limits that you have previously stated for the several gages?

A. No.

Q. How would you account for that?

A. I would account for it, if it might be in the Niagara River, for instance, that with a rapidly rising Lake Erie level at Buffalo, the river might not be in stable equilibrium as regards the flow.

Q. Suppose it were in the St. Clair River?

A. In the St. Clair River, that comes with stronger force even than the Niagara River, on account of greater length and the more complex condition entering, from Lake St. Clair's backwater effect.

Q. Taking into consideration the methods employed by the government in making these discharge measurements, what in your opinion is the probability of the gaging showing too high a discharge?

A. In which particular river?

Q. Take the St. Clair River?

A. For the mean condition as regards Lake Huron elevation and Lake St. Clair elevation, I believe the volume of discharge is accurate within one to two per cent.

Q. And if there be any error, do you think it would be more likely to show too high a discharge or too low?

A. Just as likely one side as the other. I see no reason for either having a preference.

Q. What situation might conduce to an observation showing a discharge actually in excess of that which was in the stream?

A. If when the meters were being rated, additional friction on the wheel, due to some causes that might enter, possibly a little silt on the disc or the shaft, possibly a weed caught on the wheel,—and then the instrument were taken to the river and the discharge made in which there was no silt on the meter wheel, no silt on the shaft, no weeds caught on the wheel, you might have a very small percentage greater discharge indicated, under those conditions. The probability, however, of these frictions on the disc, or on the shaft of the meter coming in, or anything in the form of weeds coming across the meter wheel, are very remote.

Q. Assuming that the meter has been correctly rated, then what situation could arise that would cause the meter to show too high a discharge?

A. A possibility enters of a little oil getting on the disc of the wheel, so that in the revolution of the wheel, instead of getting a single movement of the register, it doubles up, that is what we call skipping; that is a thing that is constantly listened for while the meters are in operation, and if that escaped the attention of the observer, your register might show a few more revolutions than were made by the meter wheel. That condition, however, is constantly watched for, and is very apparent when it does occur. It breaks the rhythm of the register sound.

Q. What would be the effect on the meter of currents in the river running obliquely to the section?

A. That is taken into account in the reduction of coefficients. We make a reduction for the direction of the current. Observations are made as to whether or not the current is cutting the section at right angles; if it is not, we introduce that into our velocity coefficients. No error will enter from that cause.

Q. What will be the effect on the meter of having the current strike it obliquely as compared with having it strike at right angles to the section?

A. The tail which controls the direction of the meter holds it nose on to the current.

Q. So that the meter always is absolutely parallel with the direction of the current?

A. Absolutely is too strong a word. I should say that the meter bears the same relation in its truthfulness with the thread of the current as it does in its truth to the direction of the rating base. If this occurs at all, it is eliminated between the rating base and the river; so that no error enters of that kind.

Q. Is a meter likely to increase the number of revolutions for a given velocity during a gaging?

A. It might, yes.

Q. To what extent?

A. One to two per cent.

Q. Can you account for that?

A. The meter might show cause by this skipping I have mentioned, this oil on the disc, why it should be cleaned, and upon taking it out and cleaning it and putting a little more oil on the pivot, you might better the lubrication. The lubrication, however, has very small effect on the spinning of the wheel.

Q. If floating material such as grass or weeds were to catch on the meter, would that effect be to increase or decrease the amount of discharge shown?

A. The lodgement of weeds or grass on the meter wheels, in my experience, has been practically zero.

Q. Assuming that there was such a thing?

A. The claim made in the patent for the Haskell meter is that it will throw off weeds; that the wheel is pointed at the nose, and it is rounded for the purpose of throwing off weeds if they should come along. If a weed did lodge square across the nose, it would slow up the wheel,—give fewer revolutions.

Q. Indicate a smaller velocity of the stream?

A. Yes.

Q. Until the weed was thrown off?

A. Yes. I know of only one case where weeds have entered into consideration, and that was in the observations in the power canal at Niagara Falls, in the fall of the year. Weeds in the lower Niagara River grow to very large extent, and towards fall they are loosened up, come down the river, and for a few days in 1907, the fall of 1907, the weeds gave some considerable trouble, mainly in accumulating across the vertical standard which carries the lead weight, and across the cable. That was a transient condition and due to the fact that the power canal is below a great mass of weeds,

the mass of weeds is so great there that it is difficult to get a small boat through. It must be understood that in the Niagara River, and I presume it is true also in the St. Clair, that the rivers themselves are not silt bearing, and there are few weeds. That is equally true of the St. Lawrence; the water is running clear, and as to the coming down of weeds there, I recollect none in my experience on the St. Lawrence River.

Q. What is the effect on the discharge of the St. Clair River of a rise in Lake St. Clair, will it increase it or decrease it?

A. A rise on Lake St. Clair decreases the discharge of the St. Clair River.

Q. A fall in Lake St. Clair would increase the flow in the St. Clair River?

A. Yes.

Q. Taking the plate, Government Exhibit 1, is the effect of the elevation of Lake St. Clair, taken into effect in determining the increment of the St. Clair River?

A. The observations are platted as indicated by the Huron gauge without change, except in the case of 1901 which is explained in this note. That was adjusted.

Q. The observations as to the elevation of Lake St. Clair?

A. The 1901 observations are adjusted for the abnormal stage of Lake St. Clair. That was the ice year, in which Lake St. Clair was low.

Q. Those observations that are platted on that plate indicate the level of Lake Huron and Michigan and the discharge through the St. Clair River, and the relation that one bears to the other?

A. Yes; and when I say the elevation of Lakes Michigan and Huron, it is the elevation of Lake Huron at Harbor Beach, which is set down here.

Q. The question is are the elevations of Lake St. Clair platted on that plate in any way?

A. No.

Q. Are they taken into account in any way in determining the increment according to the formula that appears on that plate?

A. Aside from the observations of 1901, no attention is paid to Lake St. Clair. Lake St. Clair is eliminated by the relation between Huron and Lake St. Clair. I do not mean by that that any manipulation of the figures was made. I simply say the period between 1899 and 1900, excluding 1901, 1902

and 1908, Lake St. Clair is taken for that period as being at a stage that is normal.

Q. That is you assume Lake St. Clair to have a certain elevation, which you arrive at from the elevation shown in Lake Huron and not by actual gage readings in Lake St. Clair itself?

A. Derived from the gage readings, yes.

Q. Gage readings of Lake Huron?

A. Lake Huron and Lake St. Clair both; that is platting one with respect to the other, just as they are on here (indicating plate).

Q. Please explain how you took into account in determining the increment of the St. Clair River the elevation of Lake St. Clair, at the time that observations were made as to the elevation of Lake Huron, and the discharge measurements were taken?

A. The discharge observations extending through four years, 1899, 1900, 1902 and 1908, are taken as extended enough to warrant a normal relation existing between Lake St. Clair and Lake Huron.

Q. What is that normal relation?

A. It is somewhere in the vicinity of a change of one foot on Lake Huron showing a change of 0.66 of a foot on Lake St. Clair. That 0.66 enters in no wise into the making of this plate (indicating Exhibit) except as the observations of 1901, which are not used in the computation here, have been adjusted to bring them up to a normal relation of Lake St. Clair.

Q. What do you consider the normal difference between the two lakes?

A. The plat as made here is made just as if we had no gage relations on Lake St. Clair; it is ignored.

Q. That is what I was trying to get at.

A. The discharge is taken as depending on Lake Huron stage, with the understanding—

Q. And on the assumption that Lake St. Clair is in a normal relation to Lake Huron all the time, or is stationary.

A. (No answer.)

Mr. Wilkerson: Q. You ignored that because at the time of the observations the gage readings showed the relation to be normal, is that right?

A. The fact of the normal relation of Lake St. Clair with respect to Lake Huron depends entirely on the length of

time over which the observations existed, and nothing further.

Mr. Williams: Suppose that in the group of observations Lake Huron rose, and Lake St. Clair rose at the same time; would the effect of the rise in Lake St. Clair increase or decrease the apparent increment due to the change in Lake Huron?

A. If Lake St. Clair rose at such a relation or made such a proper percentage rise of Lake Huron, the increment would not be affected.

Q. Would the rise of Lake St. Clair in itself increase or decrease the apparent increment?

A. If Lake Huron remained stationary and Lake St. Clair should go up say a tenth of a foot, the discharge would be lessened about 1,600 cubic feet per second; that is at the time when the discharge was about 200,000 cubic feet per second.

Q. When the discharge was decreased to that extent, the increment would be larger?

A. The increment is the difference of the discharges per foot change in Lake Huron stage; and we have got to take into account two of them, instead of a single one, to get at the rate of change, or the increment.

Q. Assuming that the raising of Lake St. Clair would cause a decrease of flow, if Lake Huron rose a foot, that rise of Lake St. Clair would cause a decrease of the apparent increment, would it not?

A. Now, let me see: you want Lake Huron to go up a foot. What is Lake St. Clair to do meanwhile?

Q. Suppose it goes up a tenth of a foot. Suppose Lake St. Clair is stationary to start with, does not go up at all?

A. And Lake Huron goes up a foot?

Q. Yes, and the level of Lake St. Clair is not changed?

A. I do not think that our formula would give accurate results with so large a difference in Lake St. Clair and Lake Huron.

Q. Suppose that there was a rise of .2 of a foot on Lake Huron, and Lake St. Clair remained stationary?

A. That would show an increased outflow, say with an increment of 24,000 of plus about 88/100 of one per cent of the volume of flow for lessened backwater. We take the backwater effect, that is the retardation of the outflow due to Lake St. Clair as about two-thirds of one per cent for each tenth of rise in Lake St. Clair; two-thirds of one per cent

of the volume of flow. That is an approximation, and I do not know—

Q. Are you assuming Lake St. Clair has remained stationary and a rise of .2 of a foot in Lake Huron?

A. Yes.

Q. The increased flow in such an event would be how much?

A. If your base flow was 200,000, it would be about 6,570 cubic feet per second.

Q. And suppose there was a rise of .2 of a foot in Lake Huron and a rise of one-tenth of a foot in Lake St. Clair, what would be the increase of discharge in St. Clair River?

A. That would be 5,240 cubic feet per second increase.

Q. Assume both lakes rise simultaneously .2 of a foot, what would be the additional discharge of the St. Clair River?

A. That would be about 3,900 cubic feet.

Recess to June 5th, 1909, 9:30 a. m.

June 5th, 1909, 9:30 o'clock a. m.

Cross-Examination of F. C. Shenehon resumed.

Mr. Williams: Q. In dealing with the Niagara River, is it necessary to consider the changes of elevation anywhere except in Lake Erie, in determining the increment in the Niagara River?

A. As a mean of the open season flow, no.

Q. And in dealing with the St. Lawrence River, would it be necessary to consider changes of elevation anywhere other than in Lake Ontario?

A. The St. Lawrence River, at the head of the Galops Rapids is the place in the river where the elevation of the water determines the outflow; in the vicinity of the Galops Rapids.

Q. In determining the increment of the St. Lawrence River, did you observe the observations of elevation in Lake Ontario?

A. The observations of Lake Ontario are made simultaneously, that is the water surface observation, tri-daily observations at Oswego, and the self-registering gage at Tibbitts Point, which is at the head of the river; also self-registering gage at Ogdensburg. Aside from the time when ice condi-

tions enter, the elevation at any one point permits us to derive the elevations for the other three points mentioned. That is the slope in the river above Ogdensburg is something less than a foot, normally about 0.85 foot, as I recall it, and from Ogdensburg to the Galops in the neighborhood of two feet. And when the water goes down a foot at the head of the Galops Rapids, it goes down a foot and two hundredths at Ogdensburg and a foot and four hundredths in Lake Ontario. The movement is almost identical, a little bit larger on Lake Ontario.

Q. Did you take into consideration in arriving at your increment, anything other than the elevations of Lake Ontario, and your discharge measurements in the St. Lawrence River?

A. The increment as derived is with respect to the water surface at Ogdensburg.

Q. Is it necessary to take any elevations anywhere else other than Ogdensburg in arriving at the increment?

A. To arrive at the increment? None other aside from those incident to the discharge measurements on the section.

Q. Is it your opinion, Mr. Shenehon, that the average difference of elevation, or fall from Lake Huron to Lake Erie, as indicated by the observations from 1890 to 1908, will be substantially permanent?

A. The elevation for Lake Erie for that period appears to be nearly half a foot below the mean stage of Lake Erie, since 1860. The permanence of that level, and by that I presume you mean over long periods of years, as ten or twenty years, is likely to be interferred with by artificial changes. Increasing diversion at Niagara Falls may have some small influence in lowering Lake Erie; possible larger diversions in the Welland Canal; possible larger diversions in the Erie Canal.

Q. Eliminating the artificial changes, such as you have indicated, what would you say as to the probable substantial permanence of the average fall, as indicated by the observations from 1890 to date?

A. I know no reason why the difference in elevation between Lakes Huron and Erie should be largely different from the difference 8.4, for that period. And when I say that, it might vary a tenth or two either way. And in this statement I am assuming periods long enough to eliminate eccentric variation such as you pointed out in the year 1890, I believe it was.

Q. Now, going back perhaps a little: if the conditions existing today are substantially permanent conditions, and the present difference in elevation of these two lakes is not due to temporary local conditions, can you state why the difference in elevation between these two lakes for this period from 1890 to 1908 is less than it was for the period of thirty years preceding 1890?

A. In the thirty years, the earlier period to which you refer, the elevation of Lakes Michigan and Huron was 581.84, and the fall between Michigan and Huron and Erie is 8.92, as I have just computed it. In the latter period, beginning with 1890, the elevation of Lakes Michigan and Huron is 580.53, and the fall is 8.41. This shows that Lakes Michigan and Huron are 1.31 feet lower for the latter period than for the former, and that the fall between them is 0.51 feet less for the latter period, when the lakes were low, than for the earlier period when they were high. I explained yesterday that in a general way, when Lakes Michigan and Huron go down one foot, Lake Erie goes down about 70 per cent of that, .7 of one foot. In these two periods, Lakes Michigan and Huron went down 1.31, and 70 per cent of that would be .92, and the difference between these is 0.39. That checks within .12 of a foot or an inch and a half of where we would expect Lake Erie would be, knowing where Lakes Michigan and Huron were, which is a very close check.

Q. What was the average elevation of Lake Erie for the latter period as compared with the former?

A. For the earlier period, 572.92, and for the latter period 572.12; that is Erie is .8 of a foot lower, where the computation I have made would expect it to be .92 of a foot, which is within an inch and a half of—

Q. Do you ascribe the lowering of the elevation of Lake Erie entirely to the fact that the elevation of Lakes Michigan and Huron has been lowered?

A. I should say that while Lake Erie's stage depends upon the supply that it gets from the St. Clair River and Detroit River to a large extent, that its own particular elevation involves local conditions as well; and by that I mean local rainfall, runoff and evaporation and elements of that kind, that enter into the problem.

Q. Is there any other reason in your mind why Lake Erie has been, as an average elevation, .8 of a foot lower than it formerly was, except the change in elevation in Lakes Huron and Michigan?

A. I have made no analysis of the rainfall and evaporation and runoff data.

Q. Do you consider that the fall in the elevation of Lakes Huron and Michigan would be sufficient cause for the lowering of the elevation of Lake Erie?

A. I do not attempt to explain the elevations of the lakes, at any time; to say why this lake is there, or why the other lake is at that particular point. For the period mentioned, as indicated by the computation I made, the lakes seemed to bear the proper relation to each other, and that is simply a matter of history. If you plat the records of one lake with respect to the other, in a general way they line up so as to indicate a movement of 70 per cent on Erie for one foot on Lake Huron, and for the particular period that relation seems to be borne out by the computation I made very closely. If you mean local diversions, Mr. Williams, in your question, as to whether more water has been used in the Welland Canal in recent years—

Q. No. What I was trying to get at is why the level of Lakes Huron and Michigan has been lowered by 1.31 feet and the level of Lake Erie has been lowered .8 of a foot in a period from 1890 to the present time, what caused the lowering of those lakes, that is what I am trying to get at.

A. I think the inclusion in that period of the extreme low water of 1895 explains why the mean is lower than the earlier period. That as I understand was a period in which we had record low water all over the country; not only in the great lakes, but in other rivers as well. The former period includes the period of 1886, which was the record high water. Since 1860.

Q. Suppose we eliminated both of those years, you would still find, would you not—

Q. Suppose we eliminate the low water of 1895, eliminate it entirely?

Mr. Wilkerson: I understand the periods we are talking about are the periods ending in 1889 inclusive, and then commencing with 1890 and running down to 1908?

Mr. Williams: Yes.

Mr. Wilkerson: So that the high water period, high water year as they call it, is in the first period, and the low water is in the second period. That is correct isn't it?

Mr. Williams: That is correct.

Mr. Wilkerson: So there will be no compensation, if the

one would balance the other, because they are in different periods.

Mr. Williams: Eliminate them both.

The Witness: I think it should be written into the records that this latter period does contain the artificial diversions of which I have spoken, while the earlier period does not.

Q. Do you want to be understood as saying that in your opinion those artificial diversions are accountable for the lowering of the elevation?

A. I want to be very clearly understood as saying that whatever diversion has taken place at Chicago has had its effect upon the lakes, and increased diversions in the Welland Canal have doubtless had an effect on Lake Erie.

Q. The diversion through the Welland Canal amounts to how much?

A. 1800 cubic feet per second, as I understand it.

Q. And formerly it was how much?

A. When I state that, I take it from the statement of the superintendent of the Welland Canal. I have made no measurements there; the Lake Survey has made none. As to what they were the prior period, I do not know, but I assume that they have been increased somewhat.

Q. Assume that all the diversion through the Welland Canal has taken place during the second period, what would be the effect of that diversion on the level of Lakes Erie, Huron and Michigan?

A. It would be somewhat in the neighborhood of an inch on Lake Erie.

Q. Is there any other reason that you can give for the lower elevation of these lakes?

A. Other than artificial, or other artificial reasons?

Q. Any reason that appeals to your mind as a good reason why the level of the lakes is lower in the second period?

A. I think there is a fair presumption that improvements for channelways, if I am getting at what you desire, may have had some small influence in lowering the lakes.

Q. How small in your opinion?

A. And when I state that I wish to state at the same time that other changes entering into the rivers, as the building out of docks, the deposition of dredged material, the encroachments opposite cities, and so on, have tended to compensate any lowering that might come from improved channels. I do not see any evidence between these two periods, between the period of the earlier thirty years and the latter

period after 1890, in the relative elevations of Lakes Michigan and Huron, and Erie to indicate that any large change has taken place in the regimen of the St. Clair River or of the Detroit River. So far as that evidence goes, it would indicate that the compensation is very close to complete.

Q. Well, then, in your opinion, the improvements in the channels have not contributed to this lowering?

A. Have not largely lowered the levels.

Q. What we are trying to get at is, what are the elements that in your opinion have contributed to the lowering, not those which you have not found?

A. I assume that the latter period has an entire permanence, and as I stated earlier, that the lakes were during that period somewhat below the mean lake level; and I perhaps might read into the evidence here the elevation of Lakes Michigan and Huron: for the period 1865 to 1869 it is 581.12; and for the period 1870 to 1874 (these are five-year periods), 581.47; while for the period 1905 to 1908 the elevation is 581.02. The last is a period of four years, and the last four years we have compared with the period beginning at the Civil War, and for the ten years, 1865 to 1874, the mean elevation is 581.30, which is about 3½ inches higher than the water has been during the last four years. That is, a period of ten years beginning about the Civil War in which the elevation of the water surface is only 3½ inches higher than the period for the last few years. The comparison of the two periods, as the thirty year period of your former statement and the twenty year period of the latter, is not entirely conclusive as to the fact that the lakes are permanently lowering. Yet to a certain extent it is presumable that they are, by reason of the diversions to which I have already referred, by channel improvements and of possibly very small influence coming from the power development at Niagara Falls. That last I do not think would exceed over half an inch on Lake Erie.

Q. You spoke of the diversion of water through the Welland Canal lowering the level of Lake Erie. Does that affect the level of Lakes Huron and Michigan in any way?

A. On the assumption that the lowering of a foot on Lake Erie would have the backwater effect of one-third that amount on Lakes Michigan and Huron, it would, yes.

Q. The diversion through the Welland Canal is one influence which you have mentioned. The effect of that would be one inch on Lake Erie, and one-third of an inch approxi-

mately on Huron and Michigan. Now what other diversions do you have in mind when you speak of diversions—

A. There is about seven or eight hundred cubic feet in the Erie Canal. I do not think that has increased largely between the two periods.

Q. Assuming that it was all taken out during the latter period and that there was none diverted in the preceding period, how much of an effect would that have on the level of Lake Erie?

A. That is the sum of the effects of the Welland and the Erie, is that what you mean?

Q. Just the Erie. You have given us the Welland, give us the Erie alone?

A. For 800 cubic feet would be less than half an inch.

Q. In Lake Erie?

A. Yes, it would be just about a half an inch. Welland Canal I think is about an inch and the Erie Canal is less than a half an inch.

Q. And the diversion through the Welland would be 1800 cubic feet?

A. Yes.

Q. The effect on Lakes Huron and Michigan of that diversion through the Welland Canal would be about one-third of the half inch?

A. Yes, a little less than that.

Q. What other diversions are there?

A. There is a possible lowering of a half an inch due to the power companies at Niagara Falls.

Q. About 1/6 inch of a fall on Lakes Michigan and Huron from the same cause, then? Are there any other diversions?

A. I wanted to find in my report on the preservation of Niagara Falls a statement concerning the changes in Niagara River; I do not find that reference. The purport of it was to show that for any dredging of the river, creation of artificial channels for navigation, that compensating effects have been introduced by the depositing of material and by the encroachment of docks on the shore line.

Q. We are still on the question now of the diversions that you have in mind as having been responsible for the lowering of these lake levels; and in addition to diversions, any other evidence, which in your opinion contributed to that lowering.

A. I think I have stated them all; the Chicago Drainage Canal; the difference in flow in the Welland Canal (an un-

known quantity to me); possibly small effect due to the power diversions at Niagara Falls, and channel improvements.

Q. How much effect do you attribute to the diversion through the Drainage Canal?

A. In the ratio of 4,000 cubic feet to two inches and a quarter.

Q. What do you understand the diversion has been in the past nine years?

A. I do not have the total. I believe the license is to divert 4,167 cubic feet per second.

Q. You would attribute 2½ inches then about, or 2¼ inches of this lowering to the diversion at Chicago, that is in Lakes Michigan and Huron?

A. Yes.

Q. Assume that the maximum diversion through the Sanitary District Canal at Chicago has been 5,630 cubic feet per second, and figuring upon that basis, what has been the effect on the levels of Lakes Huron, Michigan and Erie?

A. That is figuring on a continuous flow of that amount since 1900?

Q. Assume that. It is more than the actual flow has been, but taking that as a maximum flow during any period, and assume that as a constant flow?

A. That is 56 hundred, roundly.

Q. Yes.

Q. Yes.

A. It, however, is not a fact that 56 hundred has been diverted continuously since 1906, so the answer is an assumption.

Q. Yes.

A. About three inches.

Q. That is for Lakes Huron—

A. That is Lake Erie.

Q. That is for Lake Erie?

A. Yes.

Q. What is the effect on Lakes Michigan and Huron?

A. Between 2¾ and 3½, speaking roundly, on Michigan and Huron.

Q. Now then, have you mentioned all the causes which occur to you as having—

A. I imagine variations in rainfall, evaporation and so on, enter in.

Q. Have you made any examination of the rainfall data for those periods?

A. No, I haven't.

Q. And if the data indicated that the rainfall had been greater during the latter period than the former, what would you say then as to that having contributed to the lowering of the lake level?

A. I should want the evaporation data and know that it was sound, taking it into account also with the rainfall data. I should want also to know the ice condition existing in the St. Clair River and the Niagara River. I should not want to make a judgment by leaving out much of the important data on which a judgment could be based.

Q. At present then, without further investigation, you know of no causes other than those which you have enumerated which in your opinion would contribute to the lowering effect which has been observed on these lakes?

A. No.

Q. We have accounted for 5 inches of the fall in Lake Erie, and 4.17 inches fall in Lakes Huron and Michigan, by assuming that the entire diversion through the Welland Canal has been, during the latter period—

A. Which I believe is not true.

Q. Which is not true?

A. I should say it is not true; I think there is no large increment through the Erie Canal.

Q. And allowing that the Erie Canal has been a source of or a means of diversion in the latter period, which had not been previously, which is not true; and assuming the maximum flow through the Sanitary District Canal, which is not true, and in spite of all those the results account for only 4.17 fall in Lakes Huron and Michigan, and a fall of 5 inches in Lake Erie. Do the fluctuations on Lake Erie depend entirely on those of Lakes Huron and Michigan?

A. Before answering that question, I would like to put in one other element that has entered into this case, I think.

Q. That is has contributed to the lowering effect?

A. Yes.

Q. All right.

A. That is the impounding of water in Lake Superior that came with the building of the International Bridge and the Chandler-Dunbar wing dam. Lake Superior was raised during this latter period by both of those effects; by the International Bridge in part, and by the Chandler-Dunbar wing dam cutting off the flow in spans one and two of the International Bridge; and whatever water was impounded in Lake

Superior at that time was held up from the lower lakes. Lake Superior made a rise of somewhere between 4 and 6 inches, as I remember it.

Q. In your opinion what would be the extent of the effect on the elevation of Lakes Michigan, Huron and Erie of the works that you have just mentioned?

A. I could not state that, without a rather long computation.

Q. Would it be greater or less than the effect on Lake Superior itself; that is the corresponding effect? You say that Lake Superior had a higher elevation of from 4 to 6 inches. Would it make more or less than 4 to 6 inches difference in the elevation of Lakes Huron, Michigan and Erie?

A Very much less. I ought to make that matter for Lake Superior a little clearer; that matter of the lowering due to Lake Superior is nothing permanent. It was simply holding up the water for a period, and then the natural outflow of the Lake Superior area is re-established; and when I say the natural outflow, the surplus waters of Lake Superior come down the St. Marys River, and the condition is the lower lakes get their proper amount of water from that time on.

Q. How long was that condition in existence?

A. Why the bridge piers went in in the latter eighties, and the Chandler-Dunbar dam in the early nineties. I do not remember the exact dates.

Q. Over how many years would you say that the effect was noticeable?

A. You are getting me into a pretty involved line of mathematics.

Q. Approximately; taking the latter period of eighteen years, how many of those latter eighteen years would you say were affected by the impounding of water in Lake Superior? Perhaps this paragraph in this report would answer the question substantially, the report of 1903 (handing witness same). Is that of any service to you?

A. That shows that the bridge piers and the—I do not know whether that term "other small streams" indicates the Chandler-Dunbar dam or not. It speaks of that between 1887 and 1892.

Q. Without reference to the actual number of years during which the elevation was affected by the impounding of water in Lake Superior part of that effect was observable during part of the thirty year period, and part during the latter period?

A. I could not answer that without extended figuring.

Q. Has the effect of that impounding disappeared at the present time; the effect on the elevation of Lakes Huron, Michigan and Erie?

A. I should say yes; I should say practically the effect had disappeared. But there is this to be said about that, Mr. Williams: The mean lake elevations will show some small effect coming from that.

Q. Whatever the effect of that impounding in Lake Superior was on the elevation of Lakes Huron and Michigan, in the way of lowering the elevation, the effect having now disappeared, may we reasonably expect that Lakes Huron and Michigan will rise to the former stage, so that they will regain the loss occasioned by that?

A. I testified I thought it had disappeared. It had, so far as the impounding of water in Lake Superior was concerned, it had regained whatever was lost by that.

Q. It has regained it?

A. I testified that was my opinion.

Q. In your opinion does that effect account for any portion of the rise in the elevation of Lakes Huron and Michigan for 1905-1908?

A. I could not answer that without extended computation; it is impossible. You are asking me to account for a rise in the lake levels or a lowering of the lake levels. We know that those things are occurring from year to year. I have attempted to state very plainly that the elements on which a determination could be made, the rainfall data, the evaporation data, of which we have practically nothing, and the inaccurate knowledge of the ice conditions in the outflow rivers, all that data is necessary.

Q. I am not asking you now, Mr. Shenehon, for an answer as to the exact effect in inches or tenths of a foot. I would like to know whether or not in your opinion any part of the rise in the elevation of Lakes Huron and Michigan from 1905 to 1908 is due to the fact that the effect on the elevation by the impounding of water in Lake Superior has disappeared; not as to the extent of it, but whether it does to any extent account for it?

A. I should not wish to answer that without an extended computation. The conditions at Sault Ste. Marie are rather involved; the power canals, tapping the lake, and the compensating works having been put in on the Canadian side, so that you are getting into a pretty complex problem in that.

Q. Before leaving that subject, Mr. Shenehon, I understand that the situation is this: that the impounding of water in Lake Superior did in your opinion have an effect on the elevation of Lakes Michigan and Huron. That effect has disappeared but you do not desire to express an opinion one way or another as to whether or not the cause having disappeared that it would not have any effect at all on the elevation of Lakes Michigan and Huron?

Mr. Wilkerson: He limited it to certain years. Your question was for a certain period, 1904-1908.

Mr. Williams: Since the effect of the impounding has disappeared.

Mr. Wilkerson: He said with reference to those years, he would not want to express an opinion without computation.

Mr. Williams: The reason I have asked the question is because I want Mr. Shenehon to have an opportunity to explain if he wants to. If he desires to leave it just as it is I am satisfied.

Mr. Wilkerson: Would you prefer to make that computation and answer the question later on?

Mr. Williams: This is not a matter of computation.

The Witness: I should prefer on that whole matter to await a computation. Whether or not the effect disappears is a thing I am a little bit in doubt of, as I think it over; and how long it might take for that effect to disappear.

Q. Then you would prefer to modify your answer?

A. I do not like to give an opinion on that right off the bat; it is rather a complex thing.

Q. Then do you want to modify your answer as to the effect having disappeared?

A. I should like to reserve that.

Mr. Wilkerson: He said he preferred to reserve the whole question.

The Witness: Yes; it is a complex question. If you are temporarily impounding water in Lake Superior, St. Marys River is supplying Lakes Michigan and Huron with less water, and the St. Clair River is carrying the water off all the while, so we are very certain to have a lowering effect due to that. Now, after Lake Superior is at a higher plane and pours out simply its normal surplus of water, I think it is very certain that Lakes Michigan and Huron would re-establish themselves as would also Lake Erie and Lake Ontario, which would also be lowered during the impounding or sub-

sequent to it. But that matter I should like to reserve and think over. I think that is the truth.

Q. And if it has not yet occurred it will at some time; that is if the effect has not entirely disappeared up to this time, it will disappear at some time?

A. Yes.

Q. Now I will ask the question propounded some time ago with reference to the fluctuations of Lake Erie: Do they depend entirely upon those of Lake Huron?

A. No; the St. Clair River supplies the largest portion of water—the St. Clair River, Detroit River, supply the largest portion of water for Lake Erie; that is the prominent supply.

Q. But there are fluctuations of Lake Erie independent of fluctuations in Lake Huron and Lake St. Clair?

A. Yes, small fluctuations.

Q. What would be the effect on the discharge of the St. Clair River of a rise of Lake Erie?

Mr. Wilkerson: Huron remaining stationary?

Mr. Williams: Huron remaining stationary?

A. It would have the effect of retarding the outflow of the St. Clair River.

Q. Then the effect of a fall in Lake Erie would be what?

A. It would have a tendency to accelerate the flow.

Mr. Wilkerson: Huron remaining stationary?

Mr. Williams: Yes.

Q. Now, in determining the increment for the St. Clair River, is the elevation of Lake Erie taken into account?

A. It was not considered except as the observations extended over a long period. It is assumed that the conditions for that period were normal. I may state further that during the seasons of 1899, 1900, 1902, Lake St. Clair which governs by its backwater effect the outflow in the St. Clair River to the extent that I have already testified was at a normal condition; and to that extent both Lake Erie and Lake St. Clair have been considered in establishing the rate of outflow from Lake Huron, or the increment.

Q. Do you consider that the relative positions of Lakes Huron and Erie, during the time of the discharge observations, from 1899 to 1908, was representative of the continued relations of the two lakes?

A. The relation of Lake Huron to Lake Erie during 1899, 1900 and 1902 (and that should be reserved to the open season when discharge observations were being made), was in accordance with the relations of those two lakes, as shown by the

terms of years from 1875 down. An attempt was made, and I think successfully, to make the increment rather favorable to the contentions of the Sanitary District in this case in the Plate Exhibit 1 by making the increment there the greatest, and when I say that, I mean the year 1901 was excluded in that determination of the increment. I should say that the line as drawn to the observations, is the computed line excluding the year 1901. And when I say the line is set down favorable to the contention of the Sanitary District, in my opinion I believe the increment is smaller and the effect is greater, as I have already testified; and the reasons, I have given for it.

Q. At the time that these discharge observations were made which form the basis of Exhibit No. 1, the level of Lake Huron and of Lake Erie was below normal, was it not; that is below the mean?

A. For the St. Clair River, the observations between the years 1899 and 1902, inclusive, are from Lake Huron elevation 579.65 to 581.39, a range of 1.74 feet.

Q. And the mean elevation is what?

A. The mean elevation of Lake Huron is 581.32.

Q. That mean is for the entire period?

A. That is from 1860 including 1908, I believe. That is the upper limit of the observations cut the mean lake level but did not extend much above it.

Q. What was the elevation of Lake Erie during the time of those observations, as compared to the mean elevation?

A. I have not that data for the seasons of the year. What I gave you there is for the times of the observations, the limits of the observations.

Q. That is for the months?

A. No, I mean those were the actual lake observations, during the observation.

Q. During the actual period?

A. During the individual measurements; the highest measurement was 581.39 and the lowest 579.65.

Q. Would you be able to state whether or not Lake Erie was above or below normal at the time these observations were made?

A. On the St. Clair River you are speaking of Mr. Williams?

Q. The observations on the St. Clair River, yes.

A. During 1900, Lake Huron shows elevation of 580.46; during 1899 (and this is the open season) Lake Erie is at

572.11; during 1900 about the same; during 1902, it is 572.20, and the mean level taken as 572.61 is the latest, and that indicates that as a mean of the season, the lakes were below the mean lake level; but for the individual months, perhaps that should be tabulated and put into the case, if you care to have it, what the elevation was for the individual months during the discharge observation.

Mr. Wilkerson: Have not the figures, which form the basis of such a computation been identified here?

A. I think so.

Mr. Williams: Assuming, Mr. Shenehon, that at the time of making these discharge observations, the relative elevation of Lakes Huron and Erie was normal; Lake Erie is at an elevation below normal. Then assume that Lake Erie was at a normal stage of elevation, and that Huron was correspondingly higher, so that they maintained their relative elevations, what effect would that higher elevation of Lake Erie and corresponding higher elevation of Lake Huron have upon the discharge of the St. Clair River?

A. Why, the discharge of the St. Clair River would be greater for a higher stage of the two lakes where they maintained their relative relation.

Q. And the increment would be larger, would it not?

A. As a rule the increment increases somewhat for higher stages.

Q. Would you be willing to express an opinion, Mr. Shenehon, as to whether or not the relations existing between Lakes Huron, St. Clair and Erie for the periods of your observation represent average conditions that may be expected to prevail in the future?

A. It depends upon what the future contains.

Q. Under normal conditions?

A. You mean assuming larger diversions at Chicago, for instance?

Q. Assuming natural conditions?

A. I see no reason why they should be largely different.

Q. Was the effect of the storage of water in Lake Superior present at the time these observations were made?

A. That whole line of questions I would rather reserve. Speaking off hand I should say some effect was present at that time, but not to an extent to interfere with the relative elevation of Lakes Michigan, Huron and Erie within such limits as we expect them, one to follow the other.

Q. You mean the relative elevations of Huron and Erie?

A. Huron and Erie, yes.

Q. Assume that the decreased difference of level between Lakes Huron and Erie, which during the past nineteen years has been on an average of about 6 inches less than that during the preceding thirty years, is due to temporary causes; and that Lake Huron may be expected to rise relatively to Lake Erie to the old average difference. If that should occur, what in your opinion would the effect be on the discharge through the St. Clair River?

A. That is, you want to get the effect of the discharge on the St. Clair River for the conditions governing the latter period of the two as compared with the former period?

Q. No. It is a hypothetical question. The last nineteen years shows that the difference in elevation between Lakes Huron and Erie is six inches less than it was during the former period of thirty years. Now, assume that that change in difference of elevation is a mere temporary change, and that in the future the difference in elevation between the two lakes will go back to what it was during the first thirty years, be six inches more than it is at present; what would the effect of the resumption of that difference of elevation be upon the discharge through the St. Clair River?

A. You assume that both Lake Erie and Lake Huron go up to the former elevation, elevation of the period of the earlier thirty years?

Q. Yes; irrespective of their both going up; if they resume the difference of elevation?

A. Of course, my belief is that the difference of elevation is practically now what it was before. When you take into consideration the stage or the elevation of the lakes, that when one goes up a foot the other goes up .7 of a foot, so for higher stages you get a bigger difference in elevation.

Q. Take my question as a hypothetical question: Assume that during the past nineteen years the difference of elevation has changed so that there is six inches less difference?

A. At a fixed elevation for Lake Huron or for Lake Erie?

Q. Take the elevations of Lakes Huron and Erie as they were during the thirty-year period; and their relative elevations?

A. Do you want me to give a quantative result what the discharge would be in cubic feet per second for a given lake elevation?

Q. No, would it be more or less?

A. For the higher elevation of the lakes as they were in the earlier period the discharge would be somewhat higher.

Q. Irrespective of the elevation of the lakes, would a resumption of the difference in elevation to the same amount as existed in the former period of itself have any effect upon the amount of the discharge?

A. No substantial effect; perhaps one per cent.; that is, I computed that Lake Erie was within .12 of a foot, as I recollect it, of where my computations for relative elevation would bring it. And I have shown in other places in my evidence that the backwater coming up from Lake Erie was somewhere in the neighborhood of 80 per cent. and that one-tenth change on Lake St. Clair, that is, an increase of one-tenth there, would have about three-quarters of one per cent. effect on the discount; two-thirds of one per cent., I think that was, so that it would be well within one per cent. I should think any change due to abnormal relations between the two would not vary more than one per cent.

Q. Do you know what the average slope between Lakes Huron and Erie was during the period of your observations?

A. Not in detail. The records that we have will show that.

Q. Assume that Lakes Erie and Huron have a certain difference of elevation during the thirty-year period. Assume that for some reason, temporary in its nature, the relative elevations changed, so that the difference in elevation is six inches less during the latter period of nineteen years. Then assume that the temporary conditions causing that change in difference disappear, and that either Lake Erie goes down or Lake Huron goes up, either one, so that the difference in elevation is six inches more than it is at the present?

Mr. Wilkerson: That is, as I understand it, you mean this: does the fact that Lake Erie is relatively higher have any tendency with reference to the level of Michigan and Huron, is that it?

Mr. Williams: No.

The Witness: You have the question as a matter of differences. If you state specific elevations for Lake Erie and Lake Huron, the difference you are getting at would show, and I could understand the question. But if the difference is gotten by Lake Huron being six inches higher up, the effect in the discharge is not the same as if Lake Erie was six inches lower down. By lowering Lake Erie you can increase your difference, or by raising Lake Huron.

Q. I am not asking for any figures in cubic feet per second.

Assume Lake Erie remains stationary, and that in order to get back the difference in elevation between the two, Lake Huron rises six inches, what would be the effect on the discharge through the St. Clair River and on the increment?

A. I think I have an answer to this now. I would make this reservation in regard to things that I figure in this way, that in case a refiguring of it shows me that I was in error as I figure it now, I may correct it in the record.

Mr. Williams: There is no objection to your making any correction that you see fit, if you find that you have made an error in your figures at any time.

The Witness: For a rise of half a foot or six inches in Huron, if Lake St. Clair should come up its proper relation also, the change in discharge would be 12,000 cubic feet according to our curve; that is, half a foot multiplied by 24,000, or by 23,820 more correctly; and on account of less backwater effect in Lake St. Clair, we would add 1,780 cubic feet to that, making it 13,780 feet, instead of 12,000 feet.

Q. What effect would that have on your increment?

A. If that relation should be maintained constant, the increment would be increased.

Q. How would that influence the effect of the diversion at Chicago?

A. It would indicate a less lowering of Lakes Michigan and Huron, should that condition become permanent.

Recess to 2 o'clock p. m.

June 5, 1909,
2 o'clock p. m.

Cross-examination of Mr. Shenehon resumed.

Mr. Williams: Mr. Shenehon, in the report of the Chief of Engineers for 1903, at page 2813, and continuing to 2817, appears a report upon the discharge measurements of the Detroit River. Were those measurements made under the direction of the Lake Survey?

A. Yes.

Q. And the tables shown on pages 2816 and 2817 are taken from original files on file in this office? Those reports are taken from data in this office?

A. I presume so. I have never personally seen the data. That was compiled before I was Principal Assistant Engineer; and I presume it is in the office.

Mr. Williams: Without offering in evidence the report, I would like to have the record show that this report by Mr. Blanchard, junior engineer, in the report of the Chief of Engineers for 1903, at pages 2813 *et seq.*, will be referred to by us hereafter.

Q. Did you ever examine these tables?

A. Not carefully. The discharge measurements of the Detroit River are not regarded by this office as having any great weight. The conditions were rather difficult.

Q. What would you say as to the degree of accuracy that was obtained in the making of these discharge measurements in the Detroit River?

A. I do not know. I have never investigated that matter of the Detroit River; I have never thought it essential. I have always thought that the discharge of the St. Clair River governed this whole proposition; and that Lake St. Clair could simply be considered an enlarged portion of the St. Clair River, and therefore the discharge measurements in the Detroit River were of little moment.

Q. If they were accurately made, they would be valuable as corroborating the results obtained in the St. Clair River, would they not?

A. I should say not, because continuity of flow is not present. Lake St. Clair acts as an intercepting reservoir in there, in between, and it is not a continuous flow. It would not correspond to two sections on the St. Clair River, as, for instance, in the Niagara or the St. Lawrence.

Q. What were the conditions which you referred to as not having been satisfactory conditions under which these measurements were made?

A. Slow current, small slope between Lake Erie and Lake St. Clair; the liability of Lake Erie to change during the discharge observation, so that the change in slope was a very considerable percentage of the total head due to the difference of level between Lake St. Clair and Lake Erie, and the complex condition arising from separating the effect of Lake St. Clair's elevation on the discharge, and Lake Erie's backwater effect on the discharge. I think I should add to that, small range in the discharge observations; that is, the stage on Lake St. Clair, during the discharge observations.

Q. Have you any information that would lead you to believe that the results shown by these measurements were inaccurate?

A. Not as regards volume of flow at mean stage of the ob-

servation. I do not know anything about what the increment is, or what its value is. I have not studied the observations in detail.

Mr. Shenehon, is this a fair statement of the situation: that you consider the results obtained from these discharge observations will be of very little value to you in arriving at the conclusions that you seek to arrive at; but that you have no doubt of the accuracy of the actual discharge, at the time of the measurements?

A. I have stated that I think the conditions were such that the measuring of the discharge becomes more difficult there.

Mr. Wilkerson: It is more difficult in the Detroit than in the St. Clair River?

A. Oh, very much, yes.

Mr. Williams: So that the measurement itself is not as accurate, and even if it were fully as accurate, the results would not be as helpful to you in arriving at your conclusions, as they would be in the St. Clair River, where the slope is greater?

A. The weight of the observations in the St. Clair River is very much greater. Lake Erie is likely to change very rapidly, and where your original slope is about 3½ feet and Lake Erie comes up a foot, making it only 2½, you have a change of condition that is likely to come during a discharge observation. I have never myself thought the measurement of the Detroit River important; and I have never thought that we had any data that was very valuable. But I have never studied in detail the discharge observations.

Mr. Wilkerson: That is as you have studied the St. Clair and the Niagara and the St. Lawrence?

A. I have studied the St. Clair to some extent, and the Niagara and the St. Lawrence to a very considerable extent.

Mr. Williams: Is it possible for Lake Huron to vary without a corresponding variation in Lake St. Clair?

A. Temporarily, for an hour or two hours or three hours.

Q. During a period required for the making of one of your observations?

A. Yes. The effect of that, however, is that it is just as likely to go down as it is to go up, that is, Huron, with Lake St. Clair remaining constant, so any error that comes in from that source is self-eliminating in a series of discharge measurements.

Q. If Lake St. Clair should remain stationary for a period and a set of discharge measurements were made on the St.

Clair River with Lake Huron varying, would it be possible from such a series of observations to determine the increment of the St. Clair River due to the changes in Lake Huron uninfluenced by Lake St. Clair?

A. That is, Lake St. Clair remaining at constant elevation, Lake Huron varies.

Q. Lake Huron varying?

A. Over a sufficient range—

Q. For a set of discharge measurements to be made?

A. Yes, your increment could be derived under those conditions.

Q. If from the observations already made on the St. Clair River a series of groups were arranged wherein Lake St. Clair was at a constant elevation for each group and Lake Huron was varying, would it be possible to determine the increment with change in Lake Huron independent of Lake St. Clair?

A. You mean following the process we actually have followed, without considering Lake St. Clair; taking into consideration the elevation of Lake Huron, the volume of flow, grouping?

Q. Yes.

A. I think so, yes.

Q. How would you do that?

A. Plat the discharge with respect to Lake Huron elevation; draw a line threading the platted observations. The increment then is the rate at which the discharge changes for each foot of change on Lake Huron.

Q. In your answer, do you assume one group or several?

A. In getting the increment?

Q. Yes.

A. A large number of groups.

Q. And do you assume Lake St. Clair to be at the same elevation for each group?

A. In constructing the chart, which is the exhibit?

Q. No, I mean in your answer now, as you have explained the method of determining this increment; do you assume that Lake St. Clair is at a constant elevation for each group, or a constant elevation for all the groups, that is the same elevation for the several groups?

A. As I understand the question, you ignored Lake St. Clair, paying no attention to what its elevation was.

Q. No. I say, you take a group of observations with Lake St. Clair at a constant elevation and Lake Huron varying.

Now in the different groups of observations, Lake St. Clair may vary, but it is constant through the several observations. Could you get an increment, determine an increment from those several groups, due to the change in elevation of Lake Huron independently of Lake St. Clair?

A. If I understand the question, it is equivalent to ignoring Lake St. Clair, just as if the river went over a cataract, and we were considering simply Lake Huron effect on the discharge. Am I right in understanding it in that way?

Q. My proposition was: Suppose we should group your observations into groups, wherein Lake St. Clair is constant for each group, of course different from group to group; and assume you would get a number of observations, I understand from your first answer that you could get an increment for Lake Huron for any position of Lake St. Clair by that process?

A. You mean out of observations already taken?

Q. Yes.

A. Or a supposititious lot of observations.

Q. No. I take it, if it were possible to get from your observations a series of observations in which Lake St. Clair was constant and Lake Huron varied—

A. By selection?

Q. —by selection, yes; you could then determine an increment for the St. Clair River with Lake St. Clair constant for that series of observations. I understood that to be your answer to the former question. Now what we were getting at was: if we took all such possible combinations in your observations and got a series of increments for each stage on Lake St. Clair, we could then determine a mean for the river in which the effect of Lake St. Clair would be eliminated, that is what I should assume?

A. I can't see that that process would be correct. If I understand it correctly, it seems to me that the increment is the increment shown with the conditions as they did exist.

Q. We would be assuming that these conditions did exist in this case. For instance, suppose that Lake St. Clair was at a certain elevation at the time that a group of observations was made, and it remained constant during that series of observations?

A. Yes.

Q. Lake Huron varied. From that group of observations, you would be able to determine the increment?

A. But it would be an abnormal increment. It would not

represent the conditions as we would meet them from week to week, month to month, and year to year.

Q. That would be a single observation and a single increment, determining it from one set of circumstances that might not recur again. But suppose that it were determined that immediately thereafter Lake St. Clair was at a different elevation when a series of observations was made, but it remained constant at that different elevation, and Lake Huron were constant, you could determine an increment for that condition of affairs also?

A. But that would be abnormal also.

Q. If you could get a series of those, each perhaps abnormal, would it be possible to get a mean increment from those several groups?

A. I should say if the individuals were abnormal and incorrect, the mean would not bring them correct as regards increments. That is, you are assuming a condition that is artificial, as regards the problem in hand. When Lake Huron rises, and the St. Clair River sends more water down into Lake St. Clair, Lake St. Clair rises because there is more water there. If Lake St. Clair is sending more water down on account of Lake Huron's rise, the supposition that Lake St. Clair would remain constant is rather—

Q. The St. Clair would not remain constant in that case, would it? From the reports of your observations, Mr. Shenehon, there are thirty-one observations where the elevation of Lake St. Clair is the same, and where in each instance the elevation of Lake Huron is different. Taking those conditions, they were natural conditions, were they not?

A. Natural, but temporary conditions, I should say; that is thirty-one out of how many observations?

Q. Thirty-one out of a series have fallen under that condition?

A. Out of two hundred or more?

Q. I do not know. As a matter of fact the majority of these observations fall into about ten groups; that is, would be included in about ten stages of Lake St. Clair?

A. Well, the effect of getting an increment in that way, which I regard as unfair and not applicable to the case we are dealing with, would be to get a larger increment, I should say. I should say it would make the increment larger, if you should consider it in that way. The proposition, as I see it, is to establish an increment which involves equivalent elevations of Lake St. Clair for Lake Huron elevations. That is

the state of nature, as I see it. Your proposition is, as I understand it, to establish an increment for a series of conditions that are not in a state of nature.

Q. They are all natural conditions?

A. That is, as a matter of fact, taking the open season for a number of months together, so that we can eliminate these little fluctuations which might be picked out of a series of observations, the condition is that when Lake Huron is at one place, Lake St. Clair is very close to another place; and when Lake Huron goes up a foot, Lake St. Clair goes up somewhere in the neighborhood of 66 per cent. of that amount. That, as the observations indicate, as the gage observations indicate, that is the relation holding between those two water surfaces.

Q. But suppose we did desire to obtain an increment based upon the variations in Lake Huron, and independently of the conditions in Lake St. Clair, how could we do it mathematically, now? Not as to whether or not it is going to do us any good after we have done that, or whether it is going to bring results that will be satisfactory to either of the litigants in this case; but the question is, mathematically how would you go about to do that?

A. There are three ways of doing it; one is to ignore Lake St. Clair entirely. Another way is to assume that it is at a fixed elevation all the while, and that Lake Huron varies. And the third way is to take note as to whether Lake St. Clair is occupying a normal position with respect to Lake Huron. If a series of observations covers a term of years, a long enough period so that Lake St. Clair holds an elevation with respect to Lake Huron that represents a state of nature, the increment derived is correct, as I see it. If on the other hand you hold Lake St. Clair stationary and move Lake Huron up and down, which I do not see is a state of nature, you get an increment, but I do not think it is a correct increment.

Q. We are not going into the question of whether it is correct or not; but would it be an increment based upon the variations of Lake Huron, without any influence being exerted by the conditions of Lake St. Clair?

A. No, Lake St. Clair's influence is present still ,although you keep it at the same elevation. What I mean is if you should take out Lake St. Clair and have a cararact there, you get your water flowing through your river, therefore Lake St. Clair is still exerting back water influence although you hold it stationary.

Q. Suppose, Mr. Shenehon, that we were to construct some sort of controlling works by which we could see to it that the level of Lake St. Clair did not vary one hundredth of an inch, and then we desired to obtain the increment based entirely upon the variations in Lake Huron, wouldn't the method that you have suggested be the method of obtaining that increment?

A. Yes.

Q. Now suppose, on the other hand, that we were able to and did succeed in maintaining Lake Huron at constant and unvarying elevation, and at the same time the elevation of Lake St. Clair should vary, what would be the method of obtaining, in that event, the increment of the St. Clair River caused by variation in the elevation of Lake St. Clair and unaffected by Lake Huron?

A. Plat your observations and draw the line.

Q. If an increment were obtained for the St. Clair River, first based upon the varying elevations of Lake Huron unaffected by the elevation of Lake St. Clair, and secondly by the varying elevations of Lake St. Clair unaffected by Lake Huron, would it then be possible by establishing the relation of changes of elevation of Lake St. Clair and Lake Huron, to compute an increment for the St. Clair River embracing the influence of both lakes?

A. Yes; that is, you get in the former case the influence of change of Lake Huron, and your backwater effect due to change in Lake St. Clair, and by combining the two you do get your equation, write out your equation—that is right.

Q. Would there be anything unfair about that method?

A. No, not provided you take both of them. If you took either of them individually, you have got an unfair result, but is is the combination of the two that gives the proper result.

Q. An increment obtained in that way would be likely to be at least approximately correct?

A. Yes.

Q. And the statement that you put in the record, Mr. Shenehon, a few months ago, that that method of obtaining increment would be unfair was based upon a misapprehension of the entire method?

A. I will repeat that and emphasizing it, taking—

Q. That was only a part of the method?

A. Taking either half by itself and not considering the other part, the thing is unfair; and that was my under-

standing of your proposition; not the conjunction of the two.

Q. You did not understand at that time what the proposition was in its entirety?

A. I had not surrounded your conception.

Q. Suppose that the observations made by you of the discharge of the St. Clair River showed that with Lake Huron at a certain elevation, and Lake St. Clair at a certain elevation; those same elevations prevailing at the time of different observations, and that the discharge as found from these observations varied from 600 to 8,600, with no change in the elevation of Lakes Huron and St. Clair, to what would you attribute the variation in discharge?

A. What do you mean by variation of from 600 to 8600?

Q. 600 cubic feet to 8600 cubic feet?

A. You mean from the mean of the lot?

Q. No, two observations, the difference between them, the stages of the two lakes being the same, they are that much apart?

A. That is how many observations?

Q. Take a series of them where it appeared that Lake Huron and Lake St. Clair were at the same elevation?

A. Half of the divergence, 4300 is a little over 2 per cent, and a divergence of 2 per cent from the mean is not an extraordinary error of observation.

Q. I ask how you account for it?

A. It is what is known as error of observation. The river might have been not in equilibrium at the time of the observation.

Mr. Wilkerson: That is it would make a difference whether you got it with an upward swing or downward swing, is that it?

A. Lake Huron during that observation might have gone up and come down again, and the mean elevation might be the same as for a case where Lake Huron went down and then came up. The direction of the travel of Lake Huron during the discharge measurements might have some influence on it. Lake Huron might be rising during one of the observations, and falling during the other; and while the mean elevation of Lake Huron is the same, the effect on the river is different. And Lake Huron is as likely to be rising as it is to be falling. In a large number of observations, the effect of this is eliminated.

Mr. Williams: If it appears from these observations that the variation in the flow of the St. Clair River amounting to

two to three thousand cubic feet per second might go unobserved, do you know whether that is true or not?

A. You mean that the error of observation might be as much as two or three thousand cubic feet in an individual observation?

Q. Yes.

A. I should say yes.

Q. If that be true, I wish you would explain to us why you think that a flow of 4,000 cubic feet, and the effect of a diversion of 4,000 cubic feet at Chicago, could be so accurately arrived at as to enable you to say it will lower the entire lake level two inches or more?

A. The question as I understand it is, if in an individual observation the error of observation may be as great as two or three thousand cubic feet per second, why our work is not so inaccurate that we cannot get the effect of influences of four thousand or five thousand at Chicago. I say that the error of a single observation is that one is large while another is small. This is what is known as a compensating error, and enters into all forms of observations, and it is eliminated in the large number of observations of a series.

Mr. Williams: I would like to have the record show that we will offer in evidence at the hearing tables 9, 10, 11, 12 and 13, appearing upon pages 2878-9 of Appendix FFF of the Report of the Chief Engineers for 1903.

Mr. Wilkerson: Are you going to offer them without any further explanation as to the manner in which they were prepared or the conditions under which they were made?

Mr. Williams: Mr. Wheeler testified as to the probable degree of accuracy of the rainfall observations and how the rainfall observations were made. And several of your witnesses have testified that they thought they were not reliable, but they were the best they had; and we want just what there is of it.

Mr. Wilkerson: Of course this is not the time to object to their reception in evidence, nor do I want to be understood as imposing on you any hard rule with reference to making these tables competent. But I suggest that if any particular tables relating to rainfall are to be offered in evidence there should be some evidence with reference to the compilation of the particular table which is offered. And I will say we would be very glad to find out who the witness is and make it easy for you to put in that testimony. I do not wish to be put in the position of consenting that these tables are to be re-

ceived as an accurate basis for computations which may be made upon them.

Mr. Williams: I am not asking counsel to stipulate that when these go in they mean one thing or another. The witnesses have testified as to what degree of accuracy they thought attaches to these tables.

Mr. Wilkerson: Mr. Wheeler's testimony is not now fresh in my mind. If in his testimony he has covered the manner in which these tables were prepared so you think that is all you would want as making them competent, there would be no necessity for recalling him on that point. I merely suggest that a table, of course, is the statement of a result which has been derived through a certain method; and I should want, and I would think you would want, the record to show the manner in which these tables had been compiled. You are not able to throw any light on that at all are you, Mr. Shenehon?

Mr. Shenehon: No.

Mr. Wilkerson: It is knowledge entirely outside the scope of your work; a matter with which you have had nothing to do. Am I correct in that?

Mr. Shenehon: Yes.

Mr. Wilkerson: I will say this, Mr. Williams: It is perfectly obvious it will be necessary for us to return, and I make this suggestion about those tables: If there is anything that occurs to you that you would want in the record to make them competent when they were offered, I would be very glad to have the witness present who can testify with reference to them. The matter having been suggested at this time, I did not want to have you understand that I was not going to object to these tables when offered at the hearing, because I think I shall object to them.

Mr. Williams: On the ground of their not being material, not on the ground that we have not laid the proper foundation. If you are going to object because the proper foundation has not been laid, we will have to call Mr. Wheeler and go into all the details as to how the tables were prepared.

Mr. Wilkerson: There are tables and tables. A table may be prepared from one set of observations which is perfectly competent, that is evident. I think that is true with reference to these discharge observations. As to the rainfall tables, I do not know how much is based on actual observation and how much is conjecture.

Mr. Williams: They are all based on actual observation,

but as every one of your witnesses testified the observations were at such different points—

Mr. Wilkerson: There was such a vast field to be covered, the points are so far apart, that the result which is reached is of necessity subject to a very large correction on account of error.

Mr. Williams: That is a matter to be addressed to the court as to the weight which he will give to the evidence, not as to the competency of the evidence itself.

Whereupon the hearing was adjourned to Tuesday, June 15, 1909, at the hour of ten o'clock, A. M.

Detroit, Michigan, June 15, 1909.

Parties met on the above date pursuant to adjournment.

WILLIAM LIVINGSTONE, was recalled for further cross-examination by Mr. Williams and testified as follows:

Q. Of the six hundred boats, approximately, mentioned by you as being owned by the members of the Lake Carriers' Association, you testified that about 70 per cent of them would be affected by a lowering of the water at these critical points?

A. I said so, approximately, yes.

Q. And then the question was as to what percentage of that 70 per cent would be affected by a change in levels of the Detroit and St. Clair Rivers?

A. Well, if you will pardon me, suppose we start with this as a basis: I find in looking over our list that we have had some changes. We have altogether 598 boats in our Association, and of these 90 are tugs and lighters, which we do not class with the others. That would be 598; I told you 600. We have had some changes, one or two losses, one or two withdrawals and some additions, so the result is today, the total number of boats we have in our Association is 598. Of these 90 are tugs and lighters; they are harbor tugs, and they are a class by themselves so that they are not affected at all. That leaves 508 steamers and barges. Some of these 508, a few, are tow barges towed behind the large vessels so that the 508 is really what we use for commercial purposes, trading purposes. The tugs, you know are used entirely for towing.

Q. Of that 508, does your estimate hold good, that is that there will be about 70 per cent affected by a change of level?

Mr. Wilkerson: If he has those figures compiled, I suggest that he might go ahead and give a complete compilation.

The Witness: Just repeat your question.

Mr. Williams: Of the 508 boats and barges in service owned by your Association, how many would be affected by a change such as has been discussed in this case in the levels of the great lakes at the critical points?

A. We have of steamers of 22 feet and over, 322. We have 22 sailing vessels. What I mean by sailing vessels are the barges that are towed behind; 322 steamers and 22 sailing vessels. That makes a total of 344. Mr. Marr, who is secretary of this Association, at my request tabulated the figures for me. Of steamers of 19 feet to 21.9, we have 76, and tow barges 10, that makes 86. That would make a total of 430 boats in our Association that would be affected if they were loaded to their full depth, we figure, by any change in the water, for instance at the Sault Locks or at Ballard's reef. That would make a total of registered tonnage of 1,837,000 tons; perhaps to be accurate it would make 1,837,737 tons. Then you asked me in addition to that about the percentage of vessels that traded from one lake to another.

Q. Yes. Have you prepared an answer to that?

A. You can't give that absolutely accurately. At the Sault of course the government officers keep an accurate account of the tonnage. In 1908, the passage of registered vessels at the Sault was 13,908. That is net tons. Everything at the Sault is computed on the two thousand pounds basis, net tons. That was 41,390,557 tons. That made the average tons per trip 2,976. Between Lake Superior and Lake Michigan (that was one of the questions you asked) there were four and a half million tons carried, or to be accurate 4,503,055 tons. Taking the average of 2976, and that is the only way we could get at it, per trip; that was the average of what passed the Sault, you understand; in other words there were 13,908 tons passed the Sault net; that amounted to 41,390,000. That made the average tons carried per trip 2979. So, take the four and a half millions of tons, there was 1513 trips made; and at 2976 tons per trip, that made the percentage of trips to Lake Michigan 10.9, or call it 11 per cent. Then between Lake Huron and Lake Superior there was 1,651,000 tons of freight carried, and averaging that on the same basis, between Lake Huron and Lake Superior, say 2976 tons per trip, that would make 555 trips. That would make the percentage of trips 4 per cent, that is from Lake Huron to Lake Superior. Then

you take between Lake Superior and Lake Erie—that is Lake Ontario inclusive, because what goes to the lake, some of it goes through the Welland Canal, there were 35,236,482 tons, and on the basis of 2976 tons per trip, that is 11,840 trips.

You want to clearly understand in giving this, this is not confined to the Lake Carriers. This takes everything in, no matter how little or big; everything that is in commission. These percentages are not confined to the Lake Carriers' Association because, although the largest tonnage on the lakes is in our Association, there is myriad of small boats that do not belong to the Association. Between Lake Superior and Lake Erie we have 35,236,482 tons; dividing that by 2976 tons per trip would make 11,840 trips. That would make the percentage of trips from Lake Superior to Lake Erie 85 per cent. I believe I testified before it would be approximately about 80 per cent. It seems to exceed that.

You have got to bear in mind, so you will get it intelligently that in making these averages there is a large number of small hookers you know, running up to a large amount, that are not in our Association. For instance the lumber carriers are not in our Association at all and a great lot of others; but all the large modern boats are in the Association; our percentage is very large.

Q. You testified, Mr. Livingstone, that you were getting out a printed list of all the boats in your Association?

A. Yes.

Q. Has that been brought out yet?

A. Mr. Marr tells me that will be out day after tomorrow. It is in the printer's hands.

Q. What is the name of the publication? Does it have any special name?

A. Just a list of vessels having membership in the Lake Carriers' Association; gives a list of all those. We will be glad to furnish you a copy.

Q. Is there any authoritative publication giving the names and dimensions of all the vessels now plying on the Great Lakes?

A. Oh, yes, the Commissioner of Navigation has a report which shows it in full.

Q. Is the Blue Book of American Shipping also an authority?

A. The report is made out by the Commissioner of Navigation in the United States, Mr. Eugene T. Chamberlain.

Q. And that Blue Book is considered an authoritative publication?

A. Oh, yes, it is supposed to be the—

Q. You gave us very briefly the other day your experience as a navigator of the Great Lakes. Will you give us a little more in detail your own experience, when you first became interested and in what way, in lake navigation?

A. I think that I first became interested in vessels, I won't be sure whether it was in 1866 or 1867; it was one of those two years. I would have to look back and see. And I became interested by buying the controlling interest in a tug called the John S. Noyes, which was a Canadian tug. I bought a couple of barges; I wanted her at that time for bringing wood down from Bear Creek, or as we call it really the river Sidney.

Q. And that was your first experience as a vessel owner?

A. That was my initial experience as a vessel owner, yes. I remember thinking I was quite a—

Q. Just go on from that and indicate the progress made by you in your career as a vessel owner?

A. We traded with her that season. That was the first boat I was interested in and consequently I happen to remember it more particularly than some others very much larger. I remember thinking, taking her up across the flats and down again, occasionally thinking I was quite a man. That was the start.

Q. Just sketch the history of your career?

A. Well, that would be rather difficult. I have been interested more or less ever since, one way and another. There was at one time here on the lakes—it is hard to explain unless you throw a little side light on it—there was a time here for instance in 1866, 1867, along about that time you know, that on the Great Lakes here 93 per cent of the tonnage was sailing vessels, and less than 7 per cent steam. You see it has become a regular transformation scene since that time because while 93 per cent of the vessels on the lakes at that time were sailing vessels and 7 per cent, less than 7 per cent were steam, today, for instance, all the figures have been changed. I think the figures if accurately taken would show about 96 per cent steam and about 4 per cent sailing vessels, and in those sailing vessels I include the barges that are towed behind, the steam barges.

Q. You are a considerable owner of lake vessels at this time?

A. I am interested more or less, yes, sir. What I was going to say was that I kept branching out. My business was on the dock, naturally would be at that time; and I think I was at that time one of the largest tug owners on the lakes here. The vessels at that time, on account of their being sailing vessels, there was a very large number of tugs used for towing vessels through. All the vessels at that time, running along down until steam began to supplant sailing vessels were all towed through the rivers. We used to build large heavy tugs, not like these little harbor tugs; and we would go away outside, way up on Lake Huron; sometimes go as far as the Straits to get the vessels; depending on whether business was dull or not, and we would tow them through the rivers. None of these vessels you know expected to sail through the rivers themselves; they were all towed from Lake Huron or Lake Erie, towed through the St. Clair River, Lake St. Clair and the Detroit River. And we had an association here in 1869, of which I was the treasurer, practically the manager of it. We found that we had more tugs than sufficient to do the business. We had some, I don't remember forty-five or fifty tugs, so we found that we had overstocked the market. So we rather pooled our issues that way; laid up the boats that we didn't want and just kept the number sufficient to do the work economically. Then as steam kept supplanting sailing vessels as the years rolled by, the demand for tugs became less all the time. I then became interested in steam barges and one thing and another.

Q. Very briefly stated, you started as a very small owner of lake craft?

A. Yes, sir.

Q. And you have grown to become one of the largest and most influential lake owners?

A. Oh, no, I do not say that; I do not say that.

Q. I am saying it.

A. Not as an owner, no, because there are some very large fleets on the lakes. For instance you take the Pittsburg Steamship Company, they have a hundred boats.

Q. Then I will withdraw my question, if I did not state it accurately.

A. I have attained more prominence, perhaps, in this way: not so much as being an owner, though I am interested in a number of fleets and all that sort of thing, but I have attained more prominence perhaps on account of my position as president of the Lake Carriers' Association.

I should have said during this time too I represented the Western Transportation Company here, a line of steamers owned at that time not by the New York Central; they did not own them then. They had a line of a dozen steamers and half a dozen passenger boats. The passenger boats ran between Buffalo and Chicago, and that is now called the Western Transit Company; now belongs to the New York Central Railroad, but at that time we ran under contract with the New York Central Railroad, so I handled these boats here as agent, represented them.

Q. Let me ask you this question: What would you say as to the opportunity presented at present for a man to start out with the same amount of capital that you had in 1866 or 1867 and alone achieve the same success that you have achieved, during that period?

A. Well, I have not said anything about achieving success, myself.

Q. I have considered it success, and assuming I am right in saying you have been a successful man, what are the opportunities today for a man to start out along the same lines, with the same amount of capital that you had at that time, and achieve the same degree of success?

A. That is a hard question to answer.

Q. Would you say a man could do it as easily now as you did then?

A. No, sir, oh no, you can readily see that.

Q. Will you give us a reason?

A. For instance, when I first went into the vessel business, the Welland Canal had not been enlarged at that time. A boat going through the Welland Canal, sailing vessel, that carried 20,000 bushels of corn, was considered a good sized vessel. And at that time, on the gold basis, we built those vessels on the basis of about a dollar a bushel; that is the cost of building. The cost of building was much smaller. And they had to be built then like a dry goods box, almost, so as to get the greatest possible carrying capacity. It was no uncommon thing then for half a dozen men, you know, to own one of these vessels. When I just turned my majority, at the time I spoke of the Noyes—if my memory serves me right, and it is pretty accurate on that—I think I put $4,400 in that boat and I borrowed half the money to do it. And you take boats now, you can see what an evolution there has been from those canal schooners, built on a gold basis, on the basis of a dollar a bushel, costing $20,000. Sometimes half a dozen men

would be interested, and the captain very frequently had some interest in her. Now, you take that class of boats today, if you shingled the lake with them from Detroit to Chicago, you would not take them as a gift, because the more you had of them the worse off you would be. It has evoluted from that little vessel of $20,000 cost until you can't build a modern vessel, such as we build today short of from—depending on her size, having 7,500 tons, and then depending on how she is fitted out—from $275,000 to four hundred odd thousand dollars. So that you see the vessel business has gone into entirely different hands; strong hands, men of capital and men of means. It had to be so. So the chances for the small men of course—don't misunderstand me in one thing in these United States of ours, and I never leave the country and come back but what I think it is bigger than the last time. There is always room at the top for the fellow that works right, and always men make a success everywhere. But I mean the chances as a general proposition; a man could not start with a small capital as he could before. It does not take but a little you know, you take about three vessels and a man gets into a million dollars or over.

Q. Now you have referred to the Lake Carriers' Association; you are the president of the Lake Carriers' Association. Will you please state the nature of the organization?

A. You have the whole of it in that book I gave you. It will give it to you more clearly than I could. It states clearly and succinctly the object of the Association. Our constitution and by-laws are printed, and Mr. Marr will send you that when he sends the other; and that will give you clearly and succinctly the object of the Association, what it is organized for and its purposes.

Q. Does the same book give the names of the members of the Association?

A. No, we have a membership list separate from that.

Q. How many members are there in the Association?

A. I can't tell you; about seventy or seventy-five.

Q. And that membership consists of corporations and individuals, I assume?

A. Oh, yes. Nearly all boats are put in corporations, on account of the way they place stock. There are practically no vessels now—that is it is exceedingly rare where a vessel is owned by an individual; almost all form corporations.

Q. So that substantially the entire membership consists of corporations owning and operating fleets on the Great Lakes?

A. Yes. If there are but three or four owners even, they prefer to have it in corporations; it handles better every way. Lots of single boats form a corporation. If she costs $400,000, they will organize under the state law and have a corporation; then they are only responsible for their stock; limited liability.

Q. How many members would you say there are?

A. Mr. Marr suggests something to me which perhaps I ought to explain to you. It is not an uncommon thing for one member to represent five or six different fleets; he will be the manager of these lines. For instance in building up fleets, they will start and build one up of two boats, and then be organized under one company, call it anything, American Company, Atlas Company; then the business progresses and he wants to build a couple more boats. He may take in the same stockholders and add some others, so there will not be exactly the same stockholders, and they will call that a different company; so that in some cases we have one man who manages really four or five corporations, and he is the representing member in our association.

Q. How many members would you say there were in your association that own only one boat, for instance?

A. Not very many.

Q. Eight or ten?

A. I should think that would cover them. Of course there are some men that have one boat. There are one or two, two or three men that have one boat, that are interested stockholders in other corporations, you understand. A man may manage one fleet and be interested in a number of others.

Q. Is the United States Steel Corporation a member of your association?

A. No, not in that name; it is the Pittsburg Steamship Company. But the Pittsburg Steamship Company is really owned by the United States Steel Corporation, and the president and general manager of that line is Mr. Harry Coulby. It is a separate organization from the United States Steel Company. It is a corporation organized of itself and by itself, but all the stock is owned by the United States Steel Corporation.

Q. What is the next largest owner in your association? I assume that the company you have just mentioned is the largest owner of vessels?

A. Yes, they are the largest single owner, have the largest number of boats.

Q. What is the next largest owner?

A. The Gilchrist Transportation Company comes next.

Q. With what other interests is that company affiliated?

A. That is entirely an independent company. The Gilchrist Transportation Company is the second largest on the lakes, and that is made up of stockholders. I don't know how many stockholders they have.

Q. It is not affiliated with one of these large corporations?

A. No, it is entirely a vessel company, organized of itself and by itself.

Q. How many boats do they have approximately?

A. They have got sixty odd.

Q. Can you recall what is the next largest owner?

A. G. A. Tomlinson; they have several corporations in their fleet. You see that is owing to the fact that they are not the same set of stockholders; there will be some stockholders in all the boats, but not all the stockholders in all the boats.

Q. And they have about how many vessels?

A. Seventeen or eighteen; I am not sure which. I think Tomlinson has the largest average of any single fleet, the largest average tonnage of any single fleet on the lakes because all his boats are modern boats and all built within the—

Q. And the next largest is what, the Cleveland Company?

A. I think the Cleveland Cliffs is probably the next largest, they and the United States Transportation Company. It is kind of a toss-up between them. The Cleveland Cliffs boats are the Cleveland Cliffs Iron Company.

Q. The Pittsburg Steamship Company, how many vessels did you say they have?

A. They have got over a hundred. 108 Mr. Marr says. Perhaps it might throw a little side light on this tonnage business if I were to say this, if you do not object: that is you know all of the smaller class of vessels, as they go out of existence, you understand they are not replaced; they are passé; they are things of the past. In other words to boil it down, the transportation problem of today is all boiled down to one sentence and that is this: what will carry the largest amount of freight for the smallest amount of money. And experience has demonstrated that the modern fleets of boats that we are building now (I don't know what they will reach in the future) for instance a ten thousand ton boat we will say; it is impossible for one of the old type boats, and we used to consider a 3,000 ton boat very large, when the 10,000 ton boat will make money and pay a good fair dividend, it would be impossible

for the smaller boat, you know, to pay expenses. We have 10,000 ton boats, for instance that with the improvements in machinery, etc., the triple expansion engines, or quads (very few quads on the lakes), that will make the round trip now, for instance, carrying 10,000 tons of ore, and their consumption of fuel would be less than some boats carrying only 2,500 or 3,000 tons. And then with all the modern machinery and every conceivable attainable thing—and there are no boats in the world that are more modern and up to date than our modern freighters, so the result is that they only carry a few more men than the smaller boats do, and they are of the cheaper class of men, because, of course you have to have officers, masters, pilots, engineers, etc., on the smaller boats the same as you do on the larger ones. Of course on the larger boats they get a little more salary, but that is small as compared with the whole, so that the fixed cost per trip of a 10,000 ton boat as against a 3,000 ton boat is not at all in proportion, you understand.

Mr. Wilkerson: About what percentage of the freight is carried by these large boats about which you are testifying?

A. What proportion of the general freight of the lakes?

Q. Yes, the boats that you speak of as the modern boats?

A. I can only estimate that now.

Q. Approximately?

A. Oh, I think 80 per cent would be a low estimate.

Q. I am distinguishing between freight on boats of that kind and what you referred to a little while ago as the package freight boat?

A. The package freight boats, all of them on the lakes, as a rule, are owned by the railroads. For instance the Western Transit Company line, that is owned by the New York Central Railroad; the Mutual Transit Company line is owned by a combination of three or four roads; the Lehigh Valley Transit line, that is owned by the Lehigh Valley road. So that outside of the railroads, there are practically no package boats. You understand package freighters are built expressly for the purpose of being the connecting water link between lake and rail; they make an all-rail rate, and that would be a trifle higher than lake and rail; so that all these boats now are either owned or controlled by the railroads, and they are built for a specific purpose, different from ore and grain, that can be handled by elevators and big clam shells, and all that sort of thing. That freight has to be handled by hand. Of course they have engine hoists that hoist it out of the hold

of the boat, but it has to be trucked; you can't handle it like grain and ore. It has to be trucked in trucks by the stevedores on the docks; trucked off the deck of the boat on to the dock. But that percentage is very small; that is a special trade of itself.

Mr. Williams: And the package freight steamers would not be particularly affected by any slight change in the level of the lakes?

A. No, I should think not. I have not investigated that specially. You take such boats, in the fall of the year they would be affected surely. I will have to look that up.

Q. You did not take them specially into consideration, or have them in mind in arriving at your conclusion as to the effect on navigation generally?

A. No, I did not, although there are some of the new order of boats they are building that have a considerable freeboard. I do not make the statement positive, but I have an impression that some of those newer boats run as much as 24 feet freeboard; but I will not state that as a fact for I might be mistaken. I think some of them are moulded for 24 feet but I will not make that as a positive statement.

Q. During the early days of navigation on the Great Lakes, I believe you have already stated that very frequently the Captain or sailing master had an interest in the vessels?

A. Quite frequently. I do not mean in all cases but in many cases.

Q. What is the general rule now?

A. Oh, well, it is the exception and not the rule now, although we have Captains on the Lakes, quite a number of them, that own stock in some of the companies. Of course you take a line like the Pittsburg Steamship Company, no outsider could own stock in that because it is a line owned by the corporation itself; the stock is all held by it. It is just one of the connecting links, you know, in their line of business.

Mr. Wilkerson: Of course there is a vast number of stockholders who hold stock in the holding company?

A. Yes, the profits of that company, I don't know how they arrange it, but it is just a subsidiary company.

Q. United States Steel Company is a holding company; it owns no property outright, but it owns stock in a large number of subsidiary companies?

A. This is one of its subsidiary companies. I will say

one thing for the company: it is one of the fairest and one of the best managed steamship companies on the lakes, in its dealings with its employes and everybody else.

Mr. Williams: Q. Is navigation interfered with to your knowledge to any considerable extent by the swiftness of currents in the St. Clair and Detroit Rivers?

A. If I understand the question clearly, of course a vessel going up stream would not go so fast, of course, as a vessel going downstream. Assuming there is a two and a half mile current, three mile current—

Mr. Wilkerson: You mean the effect of the current in producing accidents.

Mr. Williams: I want to know whether navigation is interfered with; that is whether it is more difficult to conduct a successful business in navigation where you encounter swift currents and whether there are such currents now in the Detroit and St. Clair Rivers?

A. Oh, it is always more dangerous; the liability to danger is almost always greater for a boat navigating with a current than slack water because you can readily see why.

Q. What I am getting at is: is there a sufficient current during normal conditions now in the St. Clair or Detroit River to interfere with navigation to such an extent as to make it dangerous?

A. Well, that depends altogether on circumstances. I would not say it would make it dangerous because if a man has his boat under full control and supposing he obeys all the rules of navigation, it ought not to be dangerous. But like machinery human nature is fallible and where there is a current, there is more danger than where there is slack water, and the greater the current the greater the danger.

Q. Are there such currents in the St. Clair and Detroit Rivers?

A. Yes, in the rapids and in other places. Of course in the rapids that is a dangerous spot, because you take a boat coming down a rapid, if it is meeting another boat, and there is danger of collision, she can't stop and back there, cannot control herself; whereas if it were slack water, supposing the Master or Captain desires to stop and back, and back her strong with the whole power of his engine, he may not be able to back her there where he could control her without any difficulty whatever in slack water, so a current is always more or less dangerous.

Q. Would you consider an increase in the current in the

St. Clair River or in the Detroit River objectionable to the interests of navigation?

A. Yes, sir, I would. May I say just there, there is one reason why we are constantly fighting for double channels, so that boats won't meet each other in the rivers.

Q. How swift would you say a current would have to be, to be a dangerous current?

A. I should think a four mile current would come under the head of a dangerous current, because in case of danger of collision or anything of that kind, with the difficulty in controlling, backing and stopping, you can readily see that coming down stream with her own way and the way of the current, it takes a great deal more power to stop. The boat going up stream, with the current against her she can stop very quickly, or if it was slack water. So just to avoid that very thing we have been striving, on account of the great increase in the tonnage on the lakes, which has grown by leaps and bounds the last seven years, we are trying as far as practicable to get double channels all the way up the rivers. When we get the so-called Livingstone channel down here completed, we will have a double channel there. We expect the Canadian Government to build another channel, at least we are hoping so, and from the assurances I had the last time I was at Ottawa, I think we will get it in the near future, on the Canadian side of Fighting Island; that is the Canadian island down the river here. And up in the St. Clair River, we are making double channels all the way up there.

Q. Do you know at what points there is a current substantially equal to four miles an hour?

A. The current in the St. Clair Rapids abreast of Port Huron, say from Port Huron running up to Fort Gratiot, my impression is—I do not speak by the card—my impression is that current is about six miles an hour, yet I am not positive about that. It varies a little; they used to call it seven, but that is an over statement I know.

Q. Are there any other points where there is a current of that velocity?

A. No, not on the rivers here. I do not know of any place on the Sault River that has that current, with the improvements.

Q. Suppose the channel were 21 feet deep and 500 feet wide, would it then be objectionable to have the current increased?

A. I would have to turn you over to the engineers on that. I could not figure out the difference in velocity.

Mr. Wilkerson: I wish to note an objection to this line of cross-examination, on the ground that it is not proper cross-examination of this witness, and on the further ground that the question of the determination of the modification of the current in navigable waters of the United States is one exclusively for determination by the government itself.

Mr. Williams: Q. I am just asking you, as one familiar with navigation, whether or not in your opinion, no matter what the current is today, in a channel 500 feet wide and 21 feet deep, whether you would consider it objectionable to increase the current?

A. Of course it is impossible under existing conditions not to have a current; but every foot, so to speak, that you increase the current, of course it makes navigation a little more hazardous; it is impossible to be otherwise.

Mr. Wilkerson: I assume my objection will be taken to apply to each question in this series with reference to current, without repeating it.

Mr. Williams: Yes.

Q. That would be true irrespective of the dimensions of the channel?

A. Oh, yes, that would be true. Of course the narrower the channel, the shallower the depth, the greater the danger would be. For instance you take a 500 foot channel and you have some obstruction, with our big vessels, a man would not have the room to put his helm to port or starboard and steer clear that he would have in the thousand foot channel. Another thing, the deeper you make the channel and the narrower you confine it, it stands to reason the velocity of the water would be greater. You have two men who can answer that, Mr. Randolph and Mr. Shenehon.

Q. I am speaking merely from the point of view of the practical navigator?

A. That is all I can talk from.

Q. I am asking you also as a practical proposition, and as an experienced navigator of the great lakes, which you would consider preferable, a 21 foot channel with a slow current or a 25 foot channel with a swift current, both channels having equal width?

A. You would have to give me some idea of the difference in the swiftness.

Q. Suppose the 21-foot channel had a current of a mile and a half an hour?

A. Yes.

Q. And the deeper current had a channel of say four miles an hour?

A. I would hate to tackle the four mile current; that is I would want double channels if I was going to tackle the four mile current; that is pretty swift.

Q. Well, take it two miles for the 21-foot channel, and 2½ miles for the 25-foot channel; which would you consider the best adapted to the needs of navigation?

A. If I had the money to build the boats, I would take the 25-foot channel.

Q. Assuming the present condition of navigation on the great lakes, which would you say was best adapted to the present navigable needs?

A. Oh, as we are situated at present, the 21-foot, about the 21-foot channel or thereabouts is the better channel at the present time. Why? Because you know a chain is only as strong as the weakest link in it; and it does not make any difference if you have a hundred feet of water outside, if you have only got say 19 or 20 feet in your harbors, because what governs the draft of vessels are the harbors in which you have to unload. Now, outside of the harbors, we can go to Congress, for instance, and if the engineers agree with us in our conclusions, and support it and recommend it, we can get appropriations to deepen the waters outside. But in the harbors, we run against this proposition: there are so many private interests to be consulted, and property that would have to be condemned, and all that sort of thing, a hundred and one difficulties, more than I could enumerate, that you have to contend with, that the getting of your harbors deepened, is a very, very much slower process than it is outside. So that it would take years, for instance, to accomplish the depth of harbor you would want for a 25-foot channel. That is the reason I make the statement. What you could accomplish in a comparatively short time outside is a very difficult proposition in the harbors. And that is one proposition that really is confronting navigation today, that there are many harbors or quite a number of harbors that should, even under present conditions, be deepened materially, and passages for large boats made.

Q. Would you consider, Mr. Livingstone, that an increase

in the current along the river front at Detroit would be any detriment to navigation?

A. Yes, sir, it would be some, depending on how much or how little it was.

Q. Depending on the amount of the increase?

A. Yes, sir. Where you have a current, there are always more elements of danger than where there is no current.

Q. If Lake Michigan were lowered two feet, would navigation be affected anywhere except where the water is less than 30 feet deep?

A. I think it would, sir. I would have to look the chart over; I would not want to make the statement off-hand.

Q. Where?

A. I think it would make a good deal of difference, and yet if you ask me to enumerate where, I could not at the present moment. For instance I will explain this way: They have adopted, which is by all odds the best way in the world, the Lake Survey have adopted a method of sweeping the lakes for obstructions; and the result is that since they have adopted this method and put it in force, they are continually finding obstructions that we did not know existed before. Then in addition to that, you have got to bear in mind, you take a boat in a heavy sea, heavy storm, for instance one of our big boats, let us suppose that boat draws 22 feet of water, whatever she would draw; you see she has got to have under her in a heavy storm quite a few feet of water more than that to keep her from striking the bottom.

Q. How many feet?

A. Well, it would depend on the velocity of the wind, extent of the waves, etc., how much it was tossed.

Q. Assume a violent storm?

A. A violent storm would take six feet.

Q. That would be 28 feet?

A. Yes, sir.

Q. That would make 28 feet of depth necessary, so that if the water was more than 30 feet in depth, and if it lowered two feet, you would still be within the range then?

A. Yes, but here is what you would find, based on the experience of the Lake Survey: We have found since they have adopted what I regard as the perfect way of obtaining the depths of the lake, this sweeping we have found sporadic—it is not confined in any scientific way, but in a sporadic way we find hummocks, obstructions that I think two feet would make a wonderful difference in, in many cases. In

other words we would have a great many accidents if you lowered the lake two feet that we do not have now. Every foot you lower the lake you bring obstructions in force that do not exist before. That stands to reason.

Q. At the point where those obstructions were, getting outside the limits of my question, the water would not be 30 feet deep?

A. You may take for instance the water of a lake, the average depth of it might be 30 feet, and yet there might be a number of places in that lake where there might be hummocks or rocks sticking up like that, perhaps not as abrupt as that, but we find a good many.

Q. Would navigation be interfered with except at those points where the water was not 30 feet deep?

A. Why, certainly not, why would it? I do not see how it could be. But where it was affected it would be affected bad.

Q. Certainly, but I was speaking of the point where the water was fully 30 feet deep.

A. Well, you talk about, if I understand you, if Lake Michigan was lowered 2 feet, wasn't that your question?

Q. I asked whether or not if Lake Michigan was lowered two feet navigation would be affected except in those points where the water was less than 30 feet in depth?

A. Yes, but if you lowered Lake Michigan 2 feet, it would carry the Sault River two feet, and see what a serious proposition that would be.

Q. That would make it there less than 30 feet?

A. There are lots of places we haven't got 30 feet now.

Q. I am assuming a condition where we admit that where the depth of water is less than 30 feet a lowering of two feet would be a serious interference?

A. Oh, yes.

Q. But would it be any interference anywhere else, except where the depth was less than 30 feet?

A. How would it be possible to lower Lake Michigan two feet without lowering all the harbors two feet?

Q. I concede in those harbors it would interfere, but I ask whether it would interfere anywhere except at those points where the depth of water was less than 30 feet?

A. Perhaps not. I should be afraid that like dynamite that two feet would be loaded. When we used to have on the Lime Kiln only 12 feet, we sailed over places on the lakes

that we can't get near now. Every foot makes a great difference.

Q. You just spoke of the period of time when there was only 12 feet of water on the Lime Kiln Crossing?

A. Yes, 1867, '8 and '9; yes 12 feet.

Q. For what distance was that condition prevalent?

A. At the Lime Kilns?

Q. Yes.

A. It ran down three or four, four or five miles all through the rock cut.

Q. Do you recognize any difference in the cost of fuel required to move a loaded vessel from Lake Erie to Lake Huron as compared with that required to propel the vessel from Lake Huron to Lake Erie?

A. I don't think I clearly understand that.

Q. Does it cost any more for fuel to run a vessel from Lake Erie against the current into Lake Huron than it does to run the vessel from Lake Huron back into Lake Erie?

A. You are figuring as to whether there would not be a margin in favor of the current, you mean?

Q. No. I am figuring whether or not there is a margin against the current; if it costs more to run against the current than it does to run with it?

A. Yes; I would not undertake to figure it out.

Q. What I am trying to get at is in making your estimates of costs of operating a vessel, would you figure more fuel in making the up stream trip than you would in making the down stream trip?

A. If you went loaded, yes.

Q. Loaded both ways?

A. That is assuming the draft of water was the same both ways. Yes, a little more.

Q. About how much?

A. I can't give you that; I would have to make some figures on that. The man sitting back of you ought to be able to give you that.

Q. He is not testifying and you are. I wish to get it in the record.

A. I am willing to go on record for anything I know something about, but I want you to understand the older I get, the more I find out, the less I know. But it stands to reason, let me put it this way: Supposing two boats started from Duluth, boats of exactly the same size drawing exactly the same water; one was coming down and the other going up. If both

boats make the same rate of speed, you can naturally see you would burn a little more fuel. I can't tell you just how much, but you would burn more on the boat going up against the current than you would in the other, because the resistance, displacement, everything else would be greater. But when you come to figure it out I could not give you that offhand. You understand that is based on the supposition she would make the same time. But if she went a little slower and made fewer turns, take more time, she would accomplish the same result with the same amount of fuel.

Q. How much more time would it take?

A. I would have to figure that out, because I would have to take the number of revolutions. For instance if you turned exactly the same number of revolutions, the fuel would be the same. Every turn, every revolution per minute you increase the engine, why you can readily see it would cost more fuel, a little more fuel.

Q. Suppose that the currents in the Detroit and the St. Clair Rivers were reduced say 20 per cent?

A. Yes.

Q. From what you have said, I infer you would say that would be a benefit to navigation, if you had the same depth of water?

A. Well, there is a problem comes in there that I can't answer in this way: If you take the current out entirely, it is a question in my mind if that would not reduce the level of Lake Erie, and if you reduce the level of Lake Erie then you reduce the harbors in Lake Erie.

Q. Assuming the levels of Lake Erie and Lake Huron are not changed in any respect, and the depth of water is not made any different?

A. It seems to me the level of Lake Erie is 8 inches less than Lake Michigan.

Q. Assuming there is no effect whatever on the level of any of the lakes or the depth of water through which you are navigating, or any of the channels, would the reduction of 20 per cent in the current alone be a benefit to navigation?

A. It would be a benefit to this extent, although there are experienced vessel men who might differ with me on that subject: it would be a benefit to the extent of lessening the chances of collision; that and that only. There are some men that would rather have the current and make the extra time and take the chances of collision, so there would be a difference of opinion there.

Q. Suppose under the same conditions that the currents were increased 20 per cent, would you say that was a detriment?

A. Yes, sir, I should say it was a detriment, because that would increase the elements of danger.

Q. Would you consider that it increased the expense of operation substantially in any way?

A. The expense of operation?

Q. Yes.

A. Oh, practically not. If you eliminated the question of danger of collisions, no, not particularly. A boat going up stream would take a little more fuel. A boat coming down stream would be propelled somewhat faster so the thing would about even itself up.

Q. What do you consider the season of navigation?

A. Two hundred and forty days; 235 to 240. It varies a little some years.

Q. From what time to what time?

A. From its opening, we will say, along in the latter part of April and boats usually, many of them the insurance expires on the 5th of December at noon and if a boat leaves ten minutes before noon on the 5th of December, the Insurance Company has to carry her insurance in on that trip, on the pro rata basis as to her insurance.

Q. That is the date on which the insurance rates change, the 5th of December?

A. They expire, yes, sir. There was a time here, under certain conditions policies would run to the 10th, but now the policies are made to expire on the 5th. But if you are out, you understand, supposing you are on your voyage, of course by notifying the Company and paying the pro rata, they have got to see you home, but you can't start away, unless you get a special risk.

Q. If you get a special risk, the rate is much higher?

A. Oh, yes; very much higher.

Q. And that special rate is in force from December 5th on until the opening of navigation in April?

A. Yes. You would have to pay a very much higher rate, you know; some companies might not insure you at all.

Recess to 2 p. m.

Parties met at 2 o'clock p. m.

WILLIAM LIVINGSTONE resumed the stand for further cross-examination by Mr. Williams and testified as follows:

Q. What, if anything, has the Lake Carriers Association to do with the improvements of the harbors and connecting waters of the Great Lakes?

A. What have they to do with it?

Q. Yes.

A. Only this: that, for instance, if they think there is a harbor that needs improvement, and the necessities of navigation are such that it is important for them to get the improvement, they go first to the United States engineers of the district, who have that particular district in charge, and give them their reasons, give the engineer in charge their reasons why a certain thing should be done, and urge its being done, and then they go to Washington, if Congress is in session; go before the Rivers and Harbors Committee, if it is a subject that comes before them, and they have a hearing before the Rivers and Harbors Committee, give them the reasons why and wherefore, that this is a needed improvement, and that it should be done.

Q. It is a persuasive influence only?

A. Oh, entirely, Mr. Williams. Of course, if the Rivers and Harbors Committee, or whatever the committee is—depends on what it is; it may be the Light House Board; it might be something in the War Department; depends on each particular department the thing you want comes under.

Q. What I wanted to get at was this: does the Lake Carriers Association, or any member of it, contribute either directly or indirectly in any way to these improvements, from a financial point of view?

A. No, sir. I will have to qualify that perhaps on reflection in this way: that we have lights which are kept and paid for by the Lake Carriers Association.

Q. You have what?

A. Lights, aids to navigation of that kind, and if there was a wreck, for instance, in the way of navigation, there is always a good deal of delay; there is always a good deal of red tape about everything pertaining to the government, and if it is in the way we promptly light it and see that it is

lighted. We have a lot of aids to navigation that we pay for exclusively.

Q. My inquiry went only to the question of deepening and improving the channels.

A. That we go to Congress for, and when we want light houses and so forth, we go to the Lighthouse Department, and the Rivers and Harbors.

Re-direct Examination by Mr. Wilkerson.

Q. In your cross-examination this morning, Mr. Livingstone, you spoke with reference to currents in rivers, and the relation of the current to navigation. What do you know about the Chicago River, for instance, now, as to the effect of the reversal of the flow there, and the current in that river on navigation?

A. I know that the current there, in that narrow river, adds very largely to the dangers of navigation there.

Q. From practical experience, you know that?

A. Yes, sir. I know that the number of bridge accidents in Chicago—

Q. Attributable to the current?

A. Yes. They are very much larger than any other harbor I know of; I should say approximately double any other harbor. The accidents are greater in number than any other port on the lakes.

Q. Has there been any change in that since the flow of the river was reversed?

A. Well, I can't talk very intelligently about that; that is from personal knowledge. The understanding was, you know, that when the lake water was turned in there, if I understood it correctly, they were to have practically slack water there, but that is not the case. I have an impression that sometimes they have a current there of about three miles an hour, but I am not sure about it. I will say this by way of conclusion, and I am sure I am right, although I am not so sure about the others; I know the number of bridge accidents, etc., in Chicago is greater than any other port on the lakes, very much greater.

Q. With reference to the relation of the current to navigation, you spoke of two channels. I wish you would explain that a little more fully.

A. The reason I spoke of two channels was because it is like a double track on a railroad. With double channels, for

instance, a boat bound up would take one channel and boats bound down would take another, and therefore there is no meeting of boats. The great danger from collisions, you know, of boats coming together, is two boats meeting in the same channel; where the up bound boat, for instance, takes the easterly side and the down bound boat takes the westerly side, it is just like a double track on a railroad; all the trains going one way on one track and coming on the other; the danger of collision is very much minimized.

Re-cross Examination by Mr. Williams.

Q. Speaking of the number of accidents in the Chicago harbor, bridge accidents, is it not a fact that there are more bridges across the Chicago River than across any of the other rivers that you know of?

A. Well, I guess there are more. There are quite a few in Cleveland. I think there are more in the Chicago harbor. I would have to look that up before I could answer intelligently.

Mr. Williams: That is all.

Mr. Wilkerson: That is all.

FRANCIS S. SHENEHON resumed the stand and testified further as follows:

Re-direct Examination by Mr. Wilkerson.

Q. I would direct your attention, Mr. Shenehon, to two or three matters about which you testified on your direct examination: first, with reference to the effect of government improvements in harbors and channels, and the compensation which has been attempted in connection with those improvements. Is there anything which you care to add to what you have already said?

A. Yes, I would like to read an extract from my report on the preservation of Niagara Falls, an unpublished report.

Q. That contains some statements which you say are true?

A. Yes.

Q. Will you read it?

A. This is from Chapter 4, The Outflow of Lake Erie, page 21; an unpublished report. I say: "Artificial changes in the river (speaking of the Niagara River) regimen have

doubtless occurred, and these in part have restricted the flow, and have tended to raise the level of Lake Erie; and in part have made the flow more facile and tended to lower Lake Erie. The building of the International Bridge at Buffalo, whose piers and the rock banks flanking them reduced the cross section of the river at the crossing 18 per cent. doubtless raised Lake Erie. The building of the water works intake pier further up doubtless had a small conserving effect. The encroachments on the river channel for docks along the water fronts of cities like Tonawanda have a slight tendency to raise Lake Erie, and the dumping of material from dredged cuts has a very slight tendency in the same direction. On the other hand, the dredging out of river shoals facilitates the outflow and tends to lower Lake Erie, and the diversion of water above the first cascades for power purposes, by increasing the river flow, tends to lower Lake Erie. In the case, however, of a company throwing a wing dam into the river to deflect water into its intake, and diverting no more water than in a state of nature flowed in the intercepted portion of the channel, no lowering effect on the river or lake may occur. Indeed, in such a case if the water used and that wasted were less than the natural flow over the appropriated river bed, the effect might be to raise the river and Lake Erie. Any change in the river regimen between Buffalo and the rapids above the cataract coming from scour or deposition is believed to be exceedingly small, and the effect on the outflow of Lake Erie in a decade is inappreciable. Scour would serve to facilitate the flow and lower Lake Erie; deposition would serve to increase the resistance and raise Lake Erie. Such small changes as are likely to occur balance each other and the effect on the lake levels is mostly compensated."

Q. Is that all you care to add from that report?

A. Yes.

Q. Is there anything further you would like to add?

A. Yes. In regard to the Detroit River, I would like to make a statement that I have recently seen a chart which indicates that the shore line along the river front at Detroit has been reduced 350 feet by the dock improvements; and how much the decrease in river width has come from improvements on the other side of the river, I am not aware of.

Q. What would be the effect of that filling in?

A. That would be to compensate any increased outflow due to river improvements.

Now, in my prior examination, I stated that it was my

opinion that any lowering of the lakes that might have come from channel improvements was small; and since that time I have made some examinations of water levels, and I would like to introduce them.

Q. There were some questions put to you with reference to the change in the level of the lakes, computed as between two different periods arbitrarily selected. Now, have you made investigation of that, and eliminated on the one side the period of extreme high water, which tended to inflate the figures for that period, and eliminated from the other period the period of extreme low water which tended to change the average for that period? I mean have you made that computation, taking the average years, and eliminating what might be called abnormal or eccentric years?

A. I explained in my prior testimony that a comparison of the water levels for Lakes Michigan and Huron, say from 1860 down to 1890, and a later period from 1890 on to 1908, would not be a fair comparison of any permanent lowering that might have taken place in the lakes, for the reason that in the former period the record high water since 1860, which is that about 1886, comes in, and in the latter period the record low water for all time that we have any record of comes in.

Q. That was for 1905, was it?

A. Yes. The counsel for the Sanitary District, Mr. Williams, suggested that I leave those out, and I have made that computation and will give the results. I have divided the period from 1860 down to 1908, so as to include in the prior period the twenty years from 1860 to 1879, inclusive. In the second period, I have taken the years 1880, 1881, 1882. Then I have cut out five years of high water, 1883 to 1887, inclusive. I have included the years 1888 to 1894, inclusive; then cut out the four years of low water, 1895 to 1898, inclusive, and included the years 1899 to 1908, inclusive. That gives twenty years in the latter period, plus any comparison with the twenty years from 1880 down, and the results of the computation indicate for Michigan and Huron (and this is by the Milwaukee gage) an elevation of 581.71 for the earlier period and 580.90 for the latter period, which shows the elevation of the lake in the latter period .81 lower than in the earlier period. For Lake Erie, the same years indicate 572.86 for the earlier period; 572.36 for the latter period, with a lower lake level of 0.50 for the latter twenty years as compared with the prior twenty years. For Lake Ontario, the

elevation for the prior period is 246.51 and for the latter period 245.98; showing a lower water by 0.53 feet for the latter period as compared with the prior period.

Lake Superior for the same periods shows for the earlier period 602.35 and for the latter period 602.33 or practically the same elevation for the two periods.

Q. I will ask you to enumerate those years in which you say the second period ran?

A. The 29 years from 1880 to 1908, inclusive. From those years I have excluded 1883 to 1887, inclusive, five years; and 1895 to 1898, inclusive, four years more, making an exclusion of nine years. In these exclusions I have cut out the mountain peak of 1886, and cut out the valley of 1895, and I think the resulting comparison is a fair one.

Q. Along back in that period from 1883 to 1887, there was what was generally known as a period of high water, wasn't there, all over the country?

A. Oh, yes. I am not certain about its being all over the country. I think I have mentioned the fact that the period of 1895 was a period of low water all over the country. I am not certain as to how it was in 1886.

I would like to make a little further statement regarding this matter of lake levels, and make another comparison. I stated in my prior testimony that a certain relation seemed to hold between Lakes Michigan and Huron and Lake Erie. That is when Lake Michigan and Huron went up one foot, Lake Erie went up .7 of a foot, that is comparing a number of years together. But I have selected a method of comparing the relative elevations of the lakes, which does not require us to use that 70 per cent. relation. I have selected the ten years from 1864, or between 1864 and 1880, and a second ten years between 1888 and 1908, in which the elevation of Lake Erie is practically the same for each of the two periods. For the earlier period, 1864, '5, '6, '7, '8, '9, 1872, 1873, 1879 and 1880. For the latter period 1888, 1889, 1890, 1893, 1894, 1904, 1905, 1906, 1907, 1908. Now the elevation of Lake Erie for the earlier ten years is 572.48, and for the latter period it is 572.46. Now, I have added .02 to the latter period, making it 572.48, the same as the earlier period. And I have added to the latter period for Lake Michigan .03 and for Ontario .02 and for Superior .02. That gives us a very fair comparison. Now, for Michigan and Huron, for the earlier period, I have an elevation of 581.18 and for the latter period 581.06. Remembering that I have added .03 to that latter period, this shows that

for the same level of Erie, Lakes Michigan and Huron are lower by 1½ inches in the period after 1886 as compared with the latter period. For Ontario, the earlier period shows 246.16 and the latter period 246.37, indicating that Ontario is .21 foot higher for the latter period. And for Lake Superior, the earlier period shows 602.15 and the latter period 602.39, showing Lake Superior 0.24 higher for the latter period than for the prior period. This would indicate that Lakes Michigan and Huron had lowered about an inch and a half with respect to Lake Erie. That Lake Ontario should be higher in the latter period is what we expect, because the building of the Gut dam in 1903 raised the elevation, as I have previously testified, about five inches. That Lake Superior also should show higher is proper, because the building of International Bridge, the bridge piers, come in in the second period, while it was not present in the first period.

I want to state with all possible frankness and clearness that the fact of channel improvements by giving a more concentrated section for the flow of the water does have a tendency to facilitate the river flow. And I wish to state with equal clearness the compensating effects which I have spoken of, the deposition of the dredged material, the encroachments on the shore along cities, the building of docks. And the testimony of the water levels themselves indicates that the compensation is very nearly complete; not entirely complete, I should say. But the case of St. Mary's River, where I testified that the pool below the locks had been lowered one foot, I believe is not reproduced in any such measure in any of the lakes, or in the Lakes Michigan, Huron and Lake Erie. We know as a matter of fact Lake Ontario has come up, and we also know Lake Superior has come up in the period since 1888 as compared with the earlier period.

Q. Suppose the compensating effect is not complete and that by reason of the improvements in the channels, government improvement in the channels, there has been some lowering. What would you say as to the comparative effect under that condition of the diversion of this additional quantity of water at Chicago?

A. I should say that if the lakes were lowering by reason of channel improvements or scour, or from any cause, and I should have mentioned earlier the possibility of deforestation entering into the problem.

Q. What do you mean by that?

A. I mean that as the shores are cleared of the timber

and the lands are plowed that the evaporation on the land may be greater than it was in the earlier days. That whole question is one that is in dispute, and I do not care to pass on what the effect may be. I mention it simply as a possible element in the case.

Q. Well, now, proceed, on the assumption that as a result of these natural causes and artificial improvements on the part of the government there has been this lowering tendency, what would you say as to the comparative effect of the diversion at Chicago?

A. I should say that if Lakes Michigan, Huron or Erie had been lowered by these improvements for purposes of navigation, and by reason of natural causes, that any further lowering by the diversion at Chicago would be all the more serious.

Q. I direct your attention to your testimony as to the backwater effect of Lake St. Clair. Is there anything that you wish to add to what you said on that subject?

A. I wish to state that the percentage of retardation of the flow that I have stated to be two-thirds of 1 per cent. for each one-tenth change in the elevation of Lake St. Clair is a very approximate quantity, and should not be applied through any large range. It was intended to apply to a few tenths on either side of the mean condition.

Q. Is there anything further, Mr. Shenehon, that you wish to add to your testimony on these different matters?

A. There is nothing that I now think of.

Re-cross Examination by Mr. Williams.

Q. You referred in your testimony, Mr. Shenehon, to the effect of the improvement of the St. Mary's River. Is it not a fact that it was found impossible to compensate for the increased carrying capacity of the channels there, without introducing such currents as would make navigation through the improved channels very dangerous?

A. I do not know as a matter of fact the elements governing the design of the regulating works or the compensating works. I simply know that as a matter of fact the level of the water has been allowed to drop down.

Q. Do you not know as a fact that the reason it was allowed to drop down was because compensation could not be made without introducing such a current—

A. I do not know; I have never heard any explanation. I testified that at the middle Neebish a dyke was thrown through the shallow water, and I think the compensation was impossible in the middle Neebish.

Q. In your opinion, if compensation had been attempted here would it have introduced into the channel a current that would have been considerable?

A. I think the method pursued, or what has come out of it, was the proper engineering design or engineering decision.

Q. But if the attempt had been made there to compensate, in your opinion would there have been a considerable current?

A. Oh, yes; the conditions there were extreme. In the case of the middle rapids cut, they cut through almost dry land; in the case of the west Neebish, as I testified, rocks are showing above water, two or three feet of water, and they cut down to twenty odd feet of water. And the middle Neebish, I don't know the original condition there, but I imagine it is not very deep; it was less than 12 feet of water, because the old vessel track through the east Neebish had about 12 feet of water in the old days.

Q. In tabulating these elevation, dividing them into periods, why did you make the division of periods at 1880, in making your comparisons?

A. I took the first twenty years and compared it with the second group of twenty years, excluding two groups, one of five years in the 1886 period and the other of four years in the 1895 period. Taking five years out of the latter period, and only four out of the prior period would have made very little difference in the comparison.

Q. As a matter of fact the differences in elevation between Lake Huron and Lake Erie were greater during the first three years of the second period, that is 1880, 1881 and 1882, than they were for any other year after 1890, except 1901, weren't they? The difference in elevation for 1880 was 8.82, was it not?

A. 8.72, I have it.

Q. You have the whole year. I was taking the season of navigation. 8.72 is correct for the whole year. 1881 is 9.14. Suppose a comparison were made of those two periods, a period of 30 years from 1860 to 1889, omitting the years 1883 to 1887, inclusive, and taking for the second period 1890 to 1908 and excluding the years 1895 to 1898, inclusive?

A. Your exclusions in the earlier period are what?

Q. From 1883 to 1877, the same exclusions that you made except we divide at 1890, the time when these improvements were made.

Mr. Wilkerson: That is you take a 25-year period as against a 14-year period.

Mr. Williams: Practically.

Mr. Wilkerson: You have that computation, have you, Mr. Shenehon?

A. Yes. Professor Williams and myself have made the computation for two periods, the earlier period being for 25 years, that is, from 1860 to 1889, inclusive, with the exception of the years 1883 to 1887, inclusive. That is it is a 30-years period, excluding five years. The second period is from 1890 to 1908, inclusive, with the exception of 1895 to 1898, inclusive; that is four years excluded. The earlier 25-year period shows for Lakes Michigan and Huron an elevation of 581.69; the latter period 580.67. The lakes were lower in the latter period of 15 years by 1.02 feet than in the earlier period of 25 years. For the same periods for Lake Erie, we have the earlier period 572.84 feet and for the latter period 572.23, showing Lake Erie 0.61 feet lower for the latter period of 15 years than for the earlier period of 25 years. For our relation of 70 per cent. in Lake Erie to one foot in Michigan and Huron, we would expect Lake Erie to be .71 feet lower in the latter period than it was in the earlier period. This computation we have just made shows it was 0.61 lower, which is corroborative of the statement I made earlier that Lakes Michigan and Huron appear to have lowered about 1¼ inches as compared with Lake Erie. This makes it 1¼ inches. As regards the actual lake levels, the comparison of these two periods is an unbalanced one, 25 years in the former and 15 in the latter, and should be considered with reference to that selection of years.

Mr. Wilkerson: There is nothing further, Mr. Shenehon, that suggests itself to you?

A. No.

Adjourned sine die.

Cleveland, Ohio, July 8, 1909.
11 o'clock a. m.

Parties met pursuant to notice.

Present: Mr. Wilkerson and Mr. Williams.

HARRY COULBY, a witness called on behalf of the government, was first duly sworn and testified as follows:

Direct Examination by Mr. Wilkerson.

Q. What is your full name?
A. Harry Coulby.
Q. Where do you live?
A. Cleveland.
Q. What is your business?
A. President of the Pittsburg Steamship Company, lake transportation.
Q. How long have you been engaged in lines of business connected with lake transportation?
A. Since 1886.
Q. And in what different capacities?
A. Manager of steamships, docks and everything connected with lake transportation.
Q. What, in a general way, is the nature of the commerce which is carried on in the vessels of your company?
A. They carry iron ore, coal, sometimes grain.
Q. And between what points, principally, is that commerce conducted?
A. Two Harbors, Duluth, Superior, Ashland, Marquette, Escanaba and the Lake Michigan ports, Milwaukee, South Chicago, Chicago, Gary, and to all lower lake ports.
Q. And then on east, Detroit?
A. Yes, and these lower lake ports here.
Q. Cleveland?
A. Cleveland.
Q. Buffalo?
A. Buffalo, Erie, Conneaut, Ashtabula, Fairport, Lorraine, Huron, Sandusky, Toledo.
Q. What percentage of commerce of your company goes as far as Lake Superior, or comes from Lake Superior?
A. About 80 per cent. of it.
Q. Approximately how many vessels are operated by your company?

A. We own 106 vessels, and we generally charter about 100 more, in a normal season. We have about 200 ships in our employ.

Q. Now, with reference to those of your vessels in which commerce is conducted to and from points on Lake Superior, what is it that determines the size of the load that one of those vessels can carry?

A. It is the locks at the Sault.

Q. That is for vessels that are capable——

A. For the large model ships.

Q. Those that are capable of loading to a greater depth?

A. Yes.

Q. How many vessels has your company that are capable of loading to 20 feet, or more?

A. Sixty-one.

Q. Are you able to state approximately the number of tons carried on those vessels in a season?

A. About 12,500,000 tons.

Q. That is on the 61 vessels capable of loading to 20 feet, or more?

A. Yes.

Q. That is just on those 61 vessels?

A. That is on the 61 ships, we carry 12,500,000 in a season.

Q. As to the vessels that go to Lake Superior, you say the depth to which the vessels may load is determined by the water in the locks?

A. In the locks, yes.

Q. The Poe Lock?

A. Yes.

Q. How deep may the vessels that are going to Lake Superior be loaded now, do you know?

A. Nineteen feet, three, through the Poe Lock.

Mr. Williams: Three-tenths feet, or three inches?

A. Three inches.

Mr. Wilkerson: As to the vessels that are not going to Lake Superior, what determines the size of the load which they carry?

A. Ballards Reef, and the shallow waters across Lake St. Clair.

Q. And do you know to what depth those vessels may now be loaded?

A. They are loading to about 20 feet now.

Q. Are you able to state the number of tons for the average vessels, I mean the large vessels about which you have

testified, of your company, which will increase its draft one inch when loaded to a depth of about 19 or 20 feet?

A. About 100 tons to the inch.

Q. Assume that there should be a diminution in the depth of the water at these points with reference to which you have testified at the locks at the Sault and at Ballards Reef, assume a diminution of an inch, what would be the effect of that upon the quantity of freight which could be carried in these large boats?

A. It would reduce them about 100 tons per inch or 100 tons per trip.

Q. That would be for each ship?

A. Yes.

Q. Each ship per trip?

A. Yes, each voyage.

Mr. Williams: Do you go loaded both ways?

A. The round trip, for each cargo.

Mr. Wilkerson: About how many trips do one of those large vessels make in a season?

A. We average about 25 trips in a season.

Q. That is 25 round trips?

A. Yes, sir.

Q. With reference to the operating expenses, including fuel and dock and loading charges, how do those compare when a vessel draws, say 19 feet, as compared with the same vessel drawing 19 feet 6 inches?

A. There is no difference per trip in the operating charges but there would be a difference per ton, because of the reduced number of tons carried.

Q. How about the amount of fuel it would take?

A. Oh, it would not make any appreciable difference.

Q. And what do you say as to a vessel loaded 19 feet 6 inches, as compared with one loaded 30 feet?

A. It would be so slight you would almost lose sight of it. There would be no appreciable saving there.

Q. Are these 61 vessels, about which you have testified as being operated by your company, all of substantially the same size, or do they vary?

A. No, they run from 7,000 tons up to about 11,000.

Q. Can you give us approximately the dimensions of the largest of those vessels? Which is the largest?

A. The Cole is the largest, she is 605 feet long.

Q. What is the draft?

A. Fifty-eight feet beam and 32 feet deep.

Q. And if you had enough water at these critical points of navigation, how deep could you load that vessel?

A. Oh, that would be perfectly safe to 25 feet.

Q. How many vessels of approximately that size are there in the fleet of your company?

A. Of which size?

Q. The size of the one you have last testified about?

A. We have got 12; we are building two more. We will have 14 of the large size; but all of them have about the same depth; they are all of them from 30 to 32 feet deep, so that every one of those 61 ships could load to 25 feet.

Q. They could be loaded to 25 feet?

A. Yes.

Q. If you had the water?

A. If you had the water.

Q. As to all those vessels, what is the effect of a permanent lowering of the water in the lakes, one, two or three inches?

A. Every time you lower it an inch, you reduce the carrying capacity that much; reduce the earnings that much, without reducing the operating cost; in fact increase the operating cost on the per ton of freight carried, because you have a lesser number of tons per trip, over which to divide your operating cost.

Q. Are you able to give in a general way what the added expense is, or rather the added cost of transportation, due to diminishing the depth to which the vessel can be loaded, two or three inches?

A. I have not prepared any statistics on that.

Q. That could be easily determined from the figures you have given, could it?

A. Yes.

Q. How would you do that? About what is the cost per ton? If you have anything that will give us the basis for forming some idea as to what the effect of this lowering is upon the cost of transportation, I wish you would give it to us.

A. The cost of carrying the ore on about 19 feet 6 is 50 cents a ton.

Q. That is between what points?

A. That is from Lake Superior points to lower lake ports.

Q. You say that is to a depth of 19 feet 6?

A. Yes.

Q. About how many tons will one of these large vessels carry, loaded to that depth?

A. About 10,000 tons.

Q. Do you know anything with reference to the depth of the water in any of the harbors into which your boats go, as to whether or not the size of the load which can be carried is limited by the depth of the water in those harbors?

A. All the harbors have been dredged out to take care of the ships that could come over what I call the "necks of the bottle," that is the Poe Lock and Ballards Reef.

Q. Are there any which have been dredged only up to the point of taking care of the vessels which come over these points?

A. I do not think any of the harbors have been dredged beyond that point.

Q. So that as to practically all the harbors into which your vessels go, the lowering of the water in the lake would affect them?

A. It would be very disastrous to the harbors.

Q. That is to say it would affect them how?

A. It would affect the dock lines and the docks all around the harbors; I think the foundations of the docks.

Q. And with reference to the size of the load a vessel would carry into the harbor, would it have any effect on that?

A. It certainly would.

Q. The same effect as it would have with reference to going through the locks at the Sault?

A. Just the same.

Q. And through the river at Detroit?

A. Just the same.

Q. Have you any particular harbor in mind which would be affected that way?

A. Oh, I think every harbor along the south shore of Lake Erie would be affected.

Q. Are you able to state in a general way what would be the total effect upon the vessels which are operated by your company on the basis of the business for a season if there was a permanent lowering of say three inches, or six inches?

A. You mean per inch, on our 61 ships?

Q. Yes.

A. It would reduce the carrying capacity of the fleet 610 tons per trip; on 25 trips would be 15,000 tons.

Q. Is it 610 tons?

A. No, 6,100 tons.

Q. Sixty-one hundred tons?

A. Yes. That would be 152,000 tons a season.

Cross-Examination by Mr. Williams.

Q. The total tonnage of the 61 vessels that you have mentioned as having a draft of more than 20 feet, I understood you to say was about 12,500,000 a season?

A. Twelve and a half million tons.

Q. Per season?

A. Yes.

Q. And that is on the basis of not carrying to exceed 19 3 through the Poe Lock, and about 20 feet through the St. Clair River, Lake St. Clair and Ballards Reef?

A. That would be 19 feet 3; that is based on 19 feet 3, coming down, because it is the lowest draft that governs.

Mr. Wilkerson: That is 19 feet 3 for all the vessels that go to or come from Superior?

A. Yes. We do not trade many of these boats to Lake Michigan; that is from Lake Superior to Lake Erie.

Mr. Williams: All the vessels then that carry cargoes to the Lake Erie ports come from Lake Superior?

A. Not all of them.

Q. Are there any considerable number of the 61 vessels, concerning which you have testified, that get their cargoes this side of Lake Superior, and deliver——

A. Very few of those ships; occasionally we load some of them from Lake Superior to South Chicago or to Gary, and then run them down to Escanaba, and load them from Escanaba to Lake Erie; but as there is only about 20 per cent. of our business that comes from Michigan to Lake Erie, 80 per cent. of it comes through the Sault canal.

Q. So long as the draft of the vessels is limited at the Poe Locks to 19 feet 3 inches, any lowering of the Great Lakes, or any harbor or connecting water, which does not bring it below the 19 feet 3, would not have any effect on the greater portion of the navigation carried on by your company, assuming that there was still 19 feet 3?

A. Of course if there is still 19 feet 3 of water, we would be just where we are today, if the water is not lowered.

Q. So that in order to have any lowering effect on the business of your company it would have to be a lowering to an extent that would bring the water below 19 feet 3, at the present time?

A. Not necessarily.

Q. So far as the cargoes that come through the Sault locks are concerned?

A. On the present draft of water in the lakes, which of course governs the draft of water through these connecting places; the draft of water in the lakes.

Q. The Pittsburg Steamship Company is a corporation?

A. Yes.

Q. Organized under the laws of what state?

A. I think it is West Virginia.

Q. And the stock of the company is held by whom?

A. The United States Steel corporation.

Q. Who are the principal customers of the Pittsburg Steamship Company; that is, for whom is this transportation of iron ore and coal carried on by you?

A. For the subsidiary companies of the corporation.

Q. In other words, the United States Steel Corporation does its own transportation?

A. No.

Q. Carries on its own transportation through its subsidiary companies?

A. The Pittsburg Steamship Company carries part of the ore, probably 50 per cent. of the ore that the United States Steel corporation and subsidiary companies use; and then the United States Steel corporation, as the Pittsburg Steamship Company, has to go outside and charter independent ships.

Q. But does the Pittsburg Steamship Company carry any ore for any one except for the United States Steel Corporation?

A. No.

Q. Or one of its subsidiary corporations?

A. No.

Q. What percentage of the vessels owned by your company having a draft of more than 20 feet, the 61 vessels that you testified to, are loaded in both directions, when they make their trips through the season?

A. Loaded both ways?

Q. Yes.

A. You mean of the whole fleet?

Q. Of the 61 vessels?

A. Of that 61 vessels, we would not have probably over 2 per cent. loaded both ways.

Q. And when they are loaded going the other way, what is the nature of the cargo?

A. Coal.

Q. Do they load to the same capacity and depth as they do coming this way?

A. Yes.

Q. And for whom is the coal carried?

A. For everybody.

Q. As a common carrier?

A. We carry coal, corporation coal, and we sometimes carry coal for outside parties.

Q. Would an inch difference in draft of a vessel make the same difference in the capacity to carry coal as it would iron ore; in other words would an additional inch mean the same amount of coal?

A. Just about the same.

Mr. Wilkerson: That is, the point being whether one is as heavy as the other?

A. There is about 240 pounds difference; coal goes 2,000 pounds to the ton; ore, 2,240.

Mr. Williams: That would not affect the inch?

A. It is the inch of draft; it is not the inch of load inside the ship. It is the inch it puts the ship down that you are after.

Q. It takes the same amount of weight to put it down one inch with the one as with the other?

A. Yes, doesn't make any difference if you fill it with feathers, if you have the cubic capacity to put the ship down.

Q. Of the vessels that are chartered by your company, you say, in an ordinary season, you charter perhaps 100 vessels in addition to those owned by your company?

A. Yes.

Q. What percentage of those would you say have a draft of 20 feet or more?

A. I would say 90 per cent. of those.

Q. Have a draft of more than 20 feet?

A. Yes.

Q. What is the total tonnage of vessels operated by your company, that are owned or chartered by it, having a draft of more than 20 feet, per season?

A. The total tonnage?

Q. Yes.

A. I should say 20,000,000 tons.

Q. What would you say was the total tonnage of all your vessels of every description, both owned and chartered, whether they have a draft of more or less than 20 tons?

A. Whether they have more or less? About 23,000,000 tons.

Q. In other words the vessels having a draft of less than 20 feet would carry about 3,000,000 tons per season?

A. Yes.

Q. What is the total tonnage on the Great Lakes in a season?

A. I think about 75,000,000 tons.

Q. So that your company practically handles about 33 per cent. of the total tonnage on the Great Lakes?

A. Yes, sir.

Q. What has been the tendency during the past, say 10 years, in the building of vessels, as to size, capacity, draft?

A. Well, all the boats that cannot load to 20 feet, we scrap them or sell them as quick as we can. All the ships we build or that anybody else builds, are built looking to and hoping for a 25-foot channel.

Q. Your answer to my question as to the tendency during the past ten years is that there is a tendency to increase the tonnage capacity of vessels being built?

A. That is it.

Q. To what extent, what percentage would you say?

A. The last 10 years?

Q. Yes?

A. Oh, about 100.

Q. Looking to a capacity of 25 feet, depth of water of 25 feet at the critical points. Can you explain, just as briefly as you may, the reason why vessels are built with a draft of 32 feet, when you do not anticipate any more than a 25-foot depth of water?

A. We have to have some freeboard on a ship, to make her seaworthy.

Q. Will you explain why it is advisable, or proper, as I assume it is, to build a vessel with a greater draft than you expect to have depth of water for?

A. We have not built any of them yet.

Q. You have some now with a draft of 32 feet?

A. They are 32 feet deep; they could not load to 32 feet.

Q. You could load to 25 feet?

A. You could load them to 25 feet.

Q. They would not be capable of being loaded to more than 25 feet in any event?

A. No, I don't think so. That of course would be an engineering proposition to work out, as to what freeboard a ship ought to have. We never have got anywhere near the danger line yet.

Q. Do you know the depths at the harbors at South Chicago and Gary and Chicago?

A. No, I don't know just what depth they have there. They have got plenty of water there for the——

Q. Is it considerably deeper than the water at Ballards Reef, for instance?

A. Yes, they have deeper water there.

Q. How are the harbors at Cleveland?

A. Oh, that just depends on where you go; 21, 22 feet up the old river, and dropping down to 19 feet at the upper end of the river.

Q. Are there any other elements that you take into consideration in loading a vessel besides the depth of the water? Of course that you take into consideration first, but what other conditions would you take into consideration in determining how deep a vessel can load?

A. On these large ships that we are now talking of?

Q. Yes.

A. No other conditions but the depth of water.

Q. Does the velocity of the current in a stream have any effect on the cost of operating, or the danger of operating, or the general business of navigating the Great Lakes or connecting waters?

A. The velocity of the water makes it more dangerous to operate, of course.

Q. What velocity would you consider a dangerous current?

A. Well, that is a pretty broad question to answer. It would depend entirely on the channel, the width of the channel.

Q. Are there any dangerous currents now in any of the connecting waters of the Great Lakes?

A. No, there is only one at Port Huron; that is not dangerous; about a six-mile current through there.

Q. You think a six-mile current is not a dangerous current?

A. It is not as safe as no current at all; still it is not what you may term a dangerous current for operating ships through there.

Q. Would you consider that a decrease in the velocity of the current at any of those points where the current is from four to six miles an hour would be of advantage to navigation in any way?

A. No, not a particle.

Q. Would an increase of current be any detriment?

A. It would if you increased it enough.

Q. Any increase above six miles an hour?

A. Any increase above six miles an hour? That is a pretty broad question. That might be 6 or 10 or 25 miles. There is a danger line; I do not know what it is and nobody else knows.

Q. Assume there is a current of six miles an hour. Isn't it a fact that any increase in the velocity of that current above six miles an hour would be a detriment to navigation in the proportion the increase bore to the present current; that is a very small increase would be a slight detriment and a large increase would be a very great detriment?

A. Yes, you put it that way, and let some one else decide on the question of the small increase and the large one.

Q. Would any increase at all be a slight detriment to navigation?

A. The more you increase the current, of course, the more dangerous it becomes.

Q. Are the insurance rates based in any way on the condition of the currents, the dangers incident to swift waters?

A. No.

Q. You do not think that the insurance rate would be increased on you if the currents would be increased?

A. They would be if it increased the accidents; they are based on the accidents, the insurance rates are.

Q. And accidents would be more likely to occur with a swift current than they would with a slight current?

A. The more swift the current, the more likely you are to have accidents.

Q. Have you ever known of any accidents occurring at the Limekiln Crossing as a result of the current there?

A. I have known of a good many accidents there, but I am not prepared to say they were on account of the currents altogether.

Q. Do the currents have some contributing influence, in your opinion?

A. Yes, the currents and the crooked channel together.

Q. Now, do you know the velocity of the current through the Limekiln Crossing?

A. No, I do not know what it is there; what the current is through the Limekiln.

Q. Mr. Wilkerson asked you to make a hurried computation as to the effect upon the tonnage carried by your company

of a decrease of depth of one inch and I believe you figured 61 vessels with 100 tons per inch for each vessel, making 6,100 tons?

A. Yes.

Q. Would you say that in all your 61 vessels an inch meant 100 tons?

A. No, that would be the average. Some would go higher than 100 tons; that would be about the average.

Q. What would be the difference in tonnage for each inch in the Cole, for instance, which is the largest vessel?

A. That would probably go 120 tons. Of course the higher you go, the more she carries; that is the deeper down you go the more she carries.

Q. What would you say of the Corey?

A. Well, it would be a fraction; it would be pretty hard to tell the difference there; it would be pretty close to the same, probably 110 or somewhere along there.

Q. And you think 100 tons per inch is a fair average for the 61 vessels?

A. Yes.

Q. Do you figure that for 25 cargoes?

A. Trips, yes.

Q. For the season?

A. Yes.

Q. Do you know what the average tonnage for these 61 vessels is, for the year?

A. The average?

Q. Yes.

A. About 8,200 tons to the cargo.

Q. What is the average capacity?

A. About 200,000.

Q. The average capacity of the 61 vessels?

A. The average capacity would be about 8,200 tons.

Q. That is the average tonnage that is actually carried, is it not?

A. That is the average capacity of the 61 ships.

Q. Have they been carrying to their full capacity?

A. That is based on 19 feet 3.

Mr. Wilkerson: Of course most of them could be loaded to 25 feet?

A. They could all be loaded to 25. That is the average capacity of those ships per cargo, based on 19 feet 3 inches.

Mr. Williams: What was the actual amount carried on those 61 vessels last year?

A. I haven't got that figured up.
Q. Do you know what number of trips were made?
A. They averaged 25 trips.
Q. Was that the average for last year or the average for several trips?
A. No, that was the average for year before last, when we had a full season; that is the average full season's capacity.
Q. What was it last year?
A. I don't remember. We had a short season. We didn't get started last year until some time in June.
Q. Can you give us an approximation as to the number of trips, average number of trips for the 61 vessels last year?
A. No, I could not do that without figuring it up. I am giving you the average season's capacity of the ships.
Q. That is based upon one season, namely, season before last?
A. Based upon a season where we operate the full season.
Q. Your figures are based upon your actual experience season before last?
A. Yes.
Q. That one season?
A. Yes.
Q. You say that would be a fair average for any season providing the conditions were the same as then?
A. For 10 seasons provided the seasons average the same number of days, and we operated the entire season.
Q. But they don't always do that?
A. Without there are labor troubles, or something unusual happens.
Q. How about last season?
A. Last season they did not, because of labor troubles on the lakes.
Q. And this season?
A. This season we have had labor troubles.
Q. So that by reason of some condition, whether labor troubles or other matters, that does not make it an average for the last three seasons, does it?
A. No.
Q. What is the average cost of one of these large vessels?
A. About $400,000; $400,000 to $450,000.
Q. How many days do you consider an average season of navigation?
A. About 240.

Q. What is the operating expense of one of these large vessels, the average for the season?

A. About 50 cents a ton.

Q. Without reference to the tonnage, in dollars and cents?

A. Take the steamer Rogers, in 1907, she carried 323,000 tons of ore. Her operating expense was $127,000; about 40 cents a ton.

Q. What was the season that year, 240 days?

A. Yes. I will tell you how many days she was running, if you would like to have that.

Q. Yes.

A. She was actually operated 223 days.

Q. How many trips did she make?

A. Twenty-nine.

Q. Would you say that was a fair average of the operating expense of one of those large vessels, about $500 a day?

A. Yes, that is a fair average for operating expense.

Q. What is included in the operating expense?

A. Everything.

Q. Insurance?

A. Yes.

Q. Repairs?

A. Yes.

Q. Depreciation?

A. No.

Q. Just ordinary maintenance?

A. Just ordinary maintenance and operation.

Q. Coal?

A. Fuel, yes, everything that goes into operation but depreciation and interest.

Q. What would you consider a fair charge for depreciation and interest on a vessel of that kind?

A. Five per cent. a year.

Q. For both, or each?

A. For what?

Q. Depreciation?

A. Five per cent. a year.

Mr. Wilkerson: That is, you charge off 5 per cent. each year?

A. Yes.

Q. To get the value of the vessel?

A. That is what ought to be charged off.

Mr. Williams: What do you consider a fair charge for interest on your investment?

A. All that you can get.

Q. I mean you would charge off something for interest on your investment, before you figure any profit, wouldn't you?

A. Yes, you ought to charge off 5 per cent. a year.

Q. For interest?

A. Five per cent. a year for depreciation, and 5 per cent. a year for interest on steamship property is not enough.

Q. It is enough to start you out, and then anything above that would be profit?

A. Yes.

Q. You would not consider you were making a profit if you did not get more than 5 per cent. on your investment, would you?

A. No.

Q. So that 5 per cent. would be a fair charge for interest?

A. Yes.

Q. That is to say, the actual cost of transporting that 323,000 tons was about 40 cents a ton?

A. Yes.

Q. Does that include the unloading charge?

A. Yes, that includes the unloading charge.

Q. Does your company make a profit on that in addition? I do not want to try to get into the secrets of your business, but I mean is that what determines your earnings, what it actually costs, or do you charge the other subsidiary companies the same as you would a third party?

A. We charge the docks. We do not take it all to corporation docks. We take that ore to everybody's dock, that reaches the corporation; there is a regular dock charge for unloading.

Q. That is for unloading?

A. Yes.

Q. The charge for transportation, do you charge the actual cost, or do you charge something in addition to that?

A. We charge the actual cost of transportation, which includes the actual amount we have to pay to the dock companies for unloading it.

Q. Are the tons you speak of the vessels carrying gross tons?

A. Yes.

Q. Two thousand two hundred and forty pound tons?

A. Yes, ore goes by gross ton; coal by net.

Q. This was all iron ore that you are speaking about that the Rogers carried?

A. All iron ore that the Rogers carried; didn't carry coal at all.

Q. Do you carry your own insurance on your vessels?

A. Yes.

Q. And make a certain charge for it.

A. Yes.

Q. That is included of course in the actual cost of operation?

A. Yes.

Q. Does that include a profit to the company or is that the actual cost of carrying the insurance?

A. We charge our ships the insurance just exactly the same as it costs us to insure in old line companies, just the same rates.

Q. When was the William E. Corey built?

A. In 1906.

Q. Take the Corey for 1907, could you tell the number of days it ran, the number of trips it made and the actual operating expense?

A. The Corey was in commission 232 days. She made 29 trips. The operating expense was $123,404. You want the total tonnage now? She carried 295,802 tons; the cost was 41.7 cents per ton.

Q. What if anything has your company done, either individually or as a member of the Lake Carriers' Association towards improving the condition of navigation on the Great Lakes?

A. We do not do anything only as members of the Lake Carriers' Association.

Q. You are one of the directors of that association?

A. Yes, I am one of the directors.

Q. What have you done as an association?

A. We keep after the government, and keep trying to get them to spend money on this shallow water. The deeper the water the less per ton it costs to carry freight. The consumer pays the tax, you know.

Q. And you are working in the interest of the consumer?

A. This consumer right here. But on the broad proposition, the bigger load you can carry in a ship, the cheaper you can carry it; competition takes care of that.

Q. You are familiar with the iron ore trade I assume?

A. Yes, sir.

Q. Have you any opinion as to the length of time during which the supply of iron ore at Lake Superior will last?

A. I know just like everybody else knows that it will last until it is done; nobody knows when that will be.

Q. You haven't any opinion on the subject then?

A. Not a particle. It will last as long as I live, and I am not worrying much about the other fellow.

Q. What is the average length of time consumed in making a trip with one of these boats?

A. About nine days.

Q. For the round trip?

A. Nine days.

Q. About how long a time is consumed in loading and in unloading each, that is separately?

A. Oh, they probably load them in the average time of nine or ten hours; unload them in about the same length of time.

Q. Is there any difficulty in getting to the dock at times?

A. If the water is low.

Q. Any other difficulties?

A. None other that I know of.

Q. Suppose that there was difficulty in getting to a dock because the water was low. In your experience is it a fact or is it not, that there would be natural fluctuations in the lake level sufficient to overcome that difficulty within a few hours sometimes and sometimes within a day or two?

A. It just depends on the wind.

Q. And there are frequent variations in the depth of water in the harbors?

A. No, only in the windy season, the early spring or fall, and when we have heavy winds of course.

Q. And during the summer time, sometimes the water is driven away by heavy winds lasting for several hours?

A. It does not affect us very much in the summer. We do not get heavy winds in the summer to affect the levels of the lakes.

Q. I do not mean the lake in general, but at a particular point there might be fluctuations of several inches within a very short time?

A. Yes, not in the summer time, it does not amount to anything; you do not get wind enough to affect the water.

Q. Did you ever know of any of your vessels to be obliged to wait for a change, fluctuations in the depth of water at the Limekiln Crossing?

A. Yes, a great many times.

Q. How frequently in a season would you say that would occur?

A. Oh, I could not tell that. That comes in the early spring or in the fall, when we begin to get heavy weather.

Q. Does it ever occur in midsummer?

A. Yes, I presume it has, but so very rarely that we do not look for it or pay any attention to it.

. . . . . .

Adjourned sine die.

New York City, May 31, 1911.
1:15 o'clock, P. M.

Parties met pursuant to notice.

Present:

Mr. James H. Wilkerson, on behalf of the Government.
Mr. John C. Williams, on behalf of the Sanitary District of Chicago.

ALLAN HAZEN, a witness called on behalf of the defendant, was first duly sworn, and testified as follows:

Direct Examination by Mr. Williams.

Q. Please state your full name?

A. Allan Hazen.

Q. What is your occupation?

A. Civil engineer.

Q. You reside in the City of New York?

A. I reside in Dobbs Ferry at present.

Q. And your place of business is where?

A. Is in New York City.

Q. In what special line of civil engineering are you engaged?

A. Water supply work, sewerage and sewage disposal.

Q. Will you state the educational training and the practical experience that you have had in the line of your profession?

A. I studied at the New Hampshire State College, and afterwards at the Massachusetts Institute of Technology. From 1888 to 1892, I was at the Lawrence Experiment Station of the Massachusetts State Board of Health; the object of which

station was to determine methods of handling sewage and purifying water.

In 1893, I was in Chicago at the World's Columbian Exposition in the department of water supply, sewerage and fire protection, and operated a plant in which was treated the sewage of the fair grounds before it was discharged into the lake. I also had to do with the water supplies drawn from the lake and other sources used upon the grounds, and was familiar with the water supply system of Chicago.

Q. You were in charge of that work yourself, were you not, at the World's Fair grounds?

A. I was in charge of the sewage disposal plant under the direction of others in the department.

In 1894 I was abroad studying water supply and sewage disposal works; and also studied for a time at the Royal Technical High School at Dresden.

In 1895 and '6, I was in partnership with Mr. Noyes in Boston, as civil engineers, and commenced general work with water supply and sewerage problems, which I have followed since that time; beginning in New York in 1897.

Q. What works have you been connected with or had charge of having to do with the purification of sewage or the protection of water supply?

A. I built a few small sewage disposal works, and have advised in regard to some others; but especially, works at Altoona, Pennsylvania, at Spencer, Massachusetts, Plainfield, New Jersey; a little plant for Vassar College and a plant for the State Lunatic Hospital at Harrisburg.

I have advised cities in regard to sewage disposal problems; especially North Hampton, Massachusetts, Paterson, New Jersey, and I am advising the City of Pittsburgh at the present time.

I have designed and superintended the construction, and advised in regard to a considerable number of plants for purifying water, and have acted generally as engineer for cities and corporations in water supply matters.

Q. Have you acted in an advisory capacity in litigation involving engineering questions along the line of your experience?

A. Yes, sir, I have. I acted for the Town of Millbury in the case with the City of Worcester some years ago, involving the pollution of the Blackstone River. There are quite a number of cases of that kind. I remember being at Gloversville, New York, for the city, with reference to pollutions.

Q. Were you ever employed in any case where the Sanitary District was involved?

A. Yes, sir, I was employed by the City of St. Louis.

Q. That was the case of the *State of Missouri* v. *The Sanitary District of Chicago*?

A. It was, yes.

Q. You are now in partnership?

A. I am now in partnership with Mr. Whipple, Mr. Fuller and Mr. Babbitt. The firm name is Hazen & Whipple.

Q. Has your firm engaged recently in giving any advice in reference to sewage disposal to any city like the City of Chicago, on Lake Michigan?

A. Mr. Whipple has been a member of a commission advising Milwaukee with reference to sewage disposal, and that commission has just reported. I have been familiar with the progress of the work, but have not participated in it personally.

Q. What have you to say with reference to the City of Cleveland?

A. Mr. Whipple studied the water supply and sewerage conditions at Cleveland at considerable length; and I have had to do with those conditions at Toronto through several years.

Q. Having in mind particularly the questions relating to the matter of the purification of water supply, what particular works have you had to do with?

A. I designed and acted as engineer in the construction of the Albany Water Purification Works. I also had charge of the design, and advised with regard to the construction of the Washington, D. C., plant; and have also designed and been professionally responsible for at least a dozen smaller plants.

Q. I think you have already stated that you are now engaged in the City of Pittsburgh?

A. Yes, sir.

Q. Are you familiar with the lake and river conditions in Chicago?

A. Yes, sir, I am, to a certain extent.

Q. Over what period of time has your acquaintance extended, and to what extent have you been familiar with those conditions?

A. I first visited Chicago, I think, about 1889, and was shown the Chicago River which was pointed out as one of the notable institutions of the place. My next acquaintance with the conditions there was in 1893, when, as I have stated, I

spent the year in Chicago; and during that time I saw frequently the river conditions and the conditions along the old canal as far as Joliet and below. And I also was informed as to the water supply conditions existing at that time, and knew of some of them from personal knowledge.

Since that time, I have visited Chicago from time to time and have seen the Chicago River; have been informed as to the lake conditions, the water supply conditions.

At the time of the St. Louis suit, which has been mentioned, I made something of a study of them. At other times it has been simply the study of a very interesting phenomena professionally.

Q. Have you recently made any particular examination of the ground?

A. Yes, sir, during the last week I have been in Chicago; have been through the Chicago River and its various branches; through the Drainage Canal; have visited parts of the Calumet District, and in general looked up the things that seemed significant in the case now at issue.

Q. And from that examination, you are to some extent familiar with the qualities of the water and the effect of the sewage upon the water, at this time?

A. Yes, sir, I think I am.

Q. Are you familiar in a general way with the methods of improving the water supply of Chicago, methods that might be employed, and that are employed?

A. I am familiar with the methods that might be employed, and that are being employed in other cities.

Q. The law under which the Sanitary District is organized provides for the disposal of the sewage of the Sanitary District by dilution at the rate of 20,000 cubic feet of water per minute for each 100,000 inhabitants. I will ask you if you have an opinion as to whether or not that rate is a reasonable rate to ensure the rendering of the sewage harmless and innocuous?

Mr. Wilkerson: I object to that as incompetent, irrelevant and immaterial. The question of the reasonableness of the amount of water authorized by the Illinois statute can in no way whatsoever affect the power of Congress with reference to the matter in controversy.

A. In a general way, the legal amount of dilution is reasonable. The amount of dilution required to prevent the production of objectionable conditions is known within certain limits. Those limits are not absolutely fixed, but depend

upon various conditions, and some of those conditions are complex.

The amount required in this case might prove to be on full investigation a little greater or a little less than is fixed by law. The data that I have been able to collect during the past week, in addition to those that I had before, are not sufficient to determine this ratio precisely. I have a feeling, however, that the legal rate is at least a reasonable approximation to what is actually required for these conditions.

During my stay in Chicago, on May 23d, I went the length of the Drainage Canal and noted especially its conditions; and at my request the chemist of the district went along and made certain tests of things that I wished to know about, and it is my feeling that the water flowing in the canal on that date was carrying substantially as large a load of sewage matter as it was capable of carrying; and the record of flow given me by the chief engineer and the population tributary to the sewer, calculated at my request upon the census returns of 1910 with one year's estimated growth added, indicates that the amount of dilution on that date was very closely that corresponding to the legal dilution.

Q. You mean by legal dilution the rate established by the state law?

A. Yes, sir.

Mr. Wilkerson: 20,000 cubic feet a minute for each 100,000 inhabitants?

A. Yes.

Mr. Williams: You are familiar, are you not, Mr. Hazen, with other methods of sewage disposal, methods other than by dilution?

A. Yes, sir.

Q. Taking into consideration the fact that the Sanitary District has already expended a large amount of money approximating $66,000,000, in building its main channel, and having facilities and plans for the construction of adjuncts and additions sufficient to care for the outlying portions of the Sanitary District, I will ask you to state what is your opinion as to the most economical and appropriate method of providing for the additional sewage that may be produced within the Sanitary District during the coming few years, that is not now taken care of through the main channel?

Mr. Wilkerson: I assume that the objection which I have noted may stand to the whole line of examination, without repeating it for each particular question.

Mr. Williams: Surely.

Mr. Wilkerson: If so understood, I will not interpose an objection to each question, but it may be considered that the whole line of examination is under that objection.

Mr. Williams: I understand.

A. It is my judgment that from the standpoint of the Sanitary District, the most economical and efficient method of disposing of sewage from added population will be by extension of the existing system of dilution and discharge of the sewage towards the Illinois River. I may say that this is based upon general experience and judgment. I have made no detailed estimates of just what could be done in various ways in this case.

Q. That is insofar as the disposal of the sewage is concerned?

A. Yes, sir; but knowing a good deal of the cost of treating sewage, and the difficulties of doing it, I am perfectly clear that it would be much more expensive to treat the sewage so as to purify it and discharge it into the lake than it is to cut canals to carry lake water to dilute it and carry it harmlessly the other way.

Q. In a general way, are there any difficulties that are encountered in the treatment of sewage by methods other than dilutions, in a climate such as we have in Chicago?

A. Why, there are a great many difficulties in sewage purification. Sewage purification is comparatively a new subject. It is a new subject when carried out on any such scale as is represented by the sewage of the Sanitary District. Experience on a large scale is mostly European, and for the most part comes from places where the winter temperatures are not nearly as low as they are in Chicago.

Q. Does low temperature add to or decrease the difficulties?

A. Well, it increases the difficulties of treatment somewhat.

Q. Is there any difference in a general way between the character of the sewage in European cities and that found in American cities?

A. Yes. The European sewage is very much smaller in volume and more concentrated. In other words, the amount of water per capita is very much less, and that facilitates purification of sewage because the large quantities of water with which American sewage is diluted in the sewers render the problem of purification much more difficult.

Q. And also more expensive?

A. And also more expensive.

Q. That is per capita?

A. Per capita; probably would be cheaper per million gallons to treat dilute sewage than strong sewage, but per capita it certainly costs more.

Q. Do you know the amount of water per capita that is consumed in the City of Chicago?

A. The official records show about 230 gallons per capita for the last year.

Q. 230 gallons per day?

A. Per capita per day.

Q. And do you know what the average consumption of water per capita per day in European cities is?

A. It would range from 20 to 30 up to 50 or 60 gallons per capita daily, I should say. London uses about forty.

Q. Assuming that methods other than the dilution method were to be employed by the Sanitary District in carrying off the sewage of the additional territory, and the additional sewage produced which is not cared for by the main channel, what methods in your opinion would be most practicable?

A. I considered three possibilities for disposing of the sewage of an additional population beyond that which could be diluted by 10,000 cubic feet per second, assumed as available for the canal. I assumed as a starting point that that flow will be maintained, and that whatever sewage can be taken care of by it will continue to be so discharged.

It is necessary to state that, because with that as a starting point, the treatment of the rest of the sewage might be a little different from what it would be if that was all that there was to be considered. With that as my starting point, then, it will be possible to take care of the sewage from the added population—

Q. How much added population do you assume?

A. I assume a population of 1,200,000.

Q. That is the population that would be taken care of by 4,000 cubic feet per second, by dilution?

A. At the present legal rate, yes, sir. (Last portion of answer of the witness read, as follows: "With that as my starting point, then, it will be possible to take care of the sewage from the added population"), first by completely purifying the sewage of the added population so that the effluent may be discharged into the lake or into the lake or into the canal as may be most convenient.

Second, it will be possible to provide for it by treating a larger quantity of sewage by partial methods so that the total amount of sewage matter discharged into the canal

would not exceed that in the raw sewage from 3,000,000 people.

And third, it would be possible to let the sewage from the added population go to Lake Michigan through selected outlets, outlets selected I mean with reference to securing good dilution in the lake, and in connection therewith to purify the water supply, to protect it in that way from the polluting matter of the sewage. Which of these three general lines of treatment would be best, it is impossible to state off-hand. Very likely some combination of them would be better than either by itself; adopting each or at least two of them in places where the local conditions might lend themselves to such use.

Q. Assuming the first method were followed, namely, that works be built and operated for the complete purification of the sewage of the population assumed, in your opinion would the cost of such a plant or works be greater or less than the cost of constructing a channel such as is described in the pleadings in this case, having a capacity for a flow of 4,000 cubic feet of water per second?

A. It is my judgment that the cost would clearly be greater.

Q. You have not prepared any figures so as to be able to state to what extent the cost would be greater?

A. No, sir, I have not.

Q. Assuming the second method were employed, and works were built so that the sewage was treated, and the effluent was discharged into the lake, what is your opinion as to whether or not it would then be necessary to install any works for the purification of the water supply?

A. I think it would be desirable and necessary to purify the water in case any considerable amount of sewage effluent were discharged into the lake. It is my feeling that methods of sewage disposal now available to be used reasonably in a case like this are not adequate to protect the quality of drinking water; and if I were running the water supply I should want to protect it from the effects of sewage dilution, and I should look upon the discharge of sewage effluent from any such works as might be reasonably installed at the present time as only in a small degree less dangerous to the water supply than the discharge of crude sewage.

I am taking into account not only the theoretical possibilities of the sewage purification, but all the practical contingencies of operation that do arise in the operation of such plants.

Q. Assuming that the second method were employed, that is, the works constructed for partially purifying the sewage and the effluent discharged into the canal, would such a work or works be more or less expensive than the construction of the channel such as is proposed to be constructed by the Sanitary District, and involved in this suit?

A. Well, I can't say certainly as to that. That involves matters of design and local conditions that would have to be studied out.

Q. It would be necessary in that case to construct some kind of works to carry the effluent to the canal?

A. Oh, yes, that would be necessary. If such works were to be constructed, for instance, in the Calumet District, obviously it would require the construction of a canal similar to that which you propose, although not necessarily the same size. Of course, a sewer, a line through which the effluent was pumped, could be substituted for the canal; but in a locality with a topography like that shown by this map (referring to map spread before the witness), a canal would obviously be cheaper than any pipe line or artificial conduit.

Q. Having in mind the protection of the water supply of the City of Chicago, in your opinion would it be more advisable to discharge the raw sewage of 1,200,000 people into the lake at selected outlets, in the way you have indicated it might be done, and purify the water supply, or would it be cheaper to purify the sewage by the best method that you are acquainted with and allow the water to be used without any treatment or purification?

A. In my judgment it would clearly be better to treat the water and to allow the sewage to be discharged. It would be better because it would be more efficient in protecting the people who use the water from infectious matter from the sewage; and it would be better because it would be cheaper. I mean it is better than trying to purify the sewage and continuing to use the water without treatment.

Q. Are you familiar with the quality of the water now served to the people of Chicago?

A. Yes, sir.

Q. What did you learn in that respect?

A. In addition to my general information as to lake currents and the quality of water obtainable, I visited the Health Department of Chicago and learned what I could as to the character of the water from the different intakes as shown by their records; the water from all the intakes.

Mr. Wilkerson: In addition to the objection already noted,

let this go in subject to the further objection that it is secondary.

A. The water from all the intakes is generally of good quality. At the present time there are times when water of inferior quality is obtained from each of the intakes. The times when water of inferior quality is obtained are more frequent and last longer at the South Shore intake opposite 68th street. This is believed to be due to its being closer to the outlet of the Calumet River which is regarded as the principal local source of pollution of the lake in front of the city at this time.

Q. What effect upon this particular source of pollution would the construction of the Calumet Sag Channel and the reverse of the flow of the Calumet River have?

A. It would clearly tend to reduce this source of pollution.

Q. And suppose further that intercepting sewers were constructed to divert the sewage that otherwise empties into the river, so that it would empty directly into the canal, what effect would that have?

A. If the interception were carried to completeness, it would practically eliminate this source of pollution.

Q. Assuming, Mr. Hazen, a population of 1,200,000 people, producing sewage which is cared for by the construction of a channel with a capacity of 4,000 cubic feet of water per second and by the construction of intercepting sewers such as we have assumed in the preceding question, so that no part of the sewage of that population emptied into the lake, what is your opinion as to the necessity in that case of constructing purification works for the purpose of purifying the water supply of the city; and if such works are necessary, of what character should they be?

A. Under the assumed conditions, I believe that it would be reasonably sufficient to treat the water with hypochlorite of lime. I believe this treatment would be advantageous at the present time, and I should regard it or its equivalent as reasonably necessary under the conditions that you mentioned.

Q. What other sources of pollution are there other than the sewage which ordinarily empties into the Calumet River and the Chicago River, which would render it necessary to install purification plants?

A. There is pollution from shipping, from the dumping of various waste materials into the lake; from the sewers of other cities and towns, and there is almost certain to be

sometimes some overflow from the sewers in times of unusual rains.

Q. Have you made an estimate of the cost of such works as you have described for the treatment of the water supply of the City of Chicago by the hypochlorite system?

A. I considered the cost on the basis of the present works and the present amount of supply. I have made no very detailed estimates of the exact works, but I know from other cases some thing of what would be involved.

The cost of installing the works would not exceed $100,000; and the cost of operation for the present quantity of water may reasonably be estimated at about $60,000 per annum. The works for applying the chemical not being of the most permanent nature, I consider that 20 per cent. of the cost of construction might be taken as the annual charge, or $20,000 for the works and $60,000 for the operation, making $80,000 per annum as about the fair cost of treating the present supply of water by this method. These cost figures would increase proportionately or nearly proportionately with the amount of water drawn and used.

Q. Assume that the sewage of a population of a million two hundred thousand people were discharged in its raw state into the lake, what purification works would you then consider as proper and necessary for the protection of the water supply of the City of Chicago?

A. I consider that with such a discharge of sewage into the lake it would be desirable and reasonably necessary to filter the water before use; and I should use the hypochlorite treatment of the effluent from the filters.

The works proposed would correspond with those now being built by the City of Toronto to meet very similar conditions. The present use of water is five hundred and twenty million gallons per day. I assume that filters would be required with a nominal capacity of 40 per cent. in excess of this amount, to cover fluctuations in rate and to provide a reserve for units out of use, for cleaning or other purposes. This would call for about 120 acres of filters, operating at a rate of 6,000,000 gallons per acre daily distributed among the different intakes in proportion to capacity. These filters could be built on the lake shore, or on cheaper low lying land back of the lake shore, and not too far away from it; or just as well in shallow water near the shore.

Low lift pumps would take the water from the present tunnels to the filters and the effluent would go back into the tunnels beyond. The conditions of construction seem to be gen-

erally similar to those met at Toronto; and I am basing my idea of cost upon the prices actually being paid at Toronto. Upon this basis, the cost of the works complete with all connections with the present works, but exclusive of land, would cost about $10,000,000. The cost of land would have to be added.

I know about that only by inquiries of the most general kind, in connection with some knowledge of topography in the various locations; and I assume that the sites might reasonably cost $3,000,000, making the total cost of installation about $13,000,000.

The annual cost of operation I estimate at about half a million dollars. Both the cost of construction and operation, of course, would increase in the future in proportion or nearly in proportion to the amount of water drawn and used.

Q. If this system were installed and these works constructed, in your opinion, would it be necessary to install any additional works; would the hypochlorite system be reasonably necessary in order to render them perfectly efficient?

A. Well, I have included that in my estimate and in the statement. It would be necessary to have some added works to prevent offensive conditions in the Calumet River.

Q. Assuming that the sewage of the population assumed was completely diverted and treated by dilution through a channel such as is proposed to be constructed by the Sanitary District, and the hypochlorite system of treatment was adopted; then assume that the sewage was emptied in its raw state into the lake and the system last described by you were employed for purification of the water supply. Which would produce, in your opinion, the better result from the standpoint of purity of water?

A. As near as I can tell, or estimate ,the conditions would be about equivalent, as measured by the sanitary quality of drinking water produced.

Q. In your opinion, what would be the effect upon the lake and upon the Calumet River itself, if the sewage of 1,200,000 people in its raw state were emptied into the river and into the lake so far as producing nuisance is concerned?

A. I think the sewage of 1,200,000 people discharged mainly into the Calumet River would produce offensive conditions in it, which conditions would require some local treatment.

Q. Have you given any thought to any treatment that might be applied to obviate the nuisance thus created?

A. Yes, sir, I have given the matter some thought. In a

general way it would seem that the method of flushing that has been used by Milwaukee through a long term of years would be the best way of correcting such conditions in the Calumet River; I mean the best way looking at it as a local problem and excluding the channel which you are proposing to build.

Q. We are assuming that the channel is not built. Can you describe a little more in detail the flushing system to which you refer?

A. The flushing system at Milwaukee consists in cutting tunnels from the lake to points on the river above the points where the objectionable conditions exist and pumping water through the tunnel to produce a current in the river and to dilute the sewage discharged into the river to such an extent that it will not become objectionable.

Q. And also creating a current?

A. It also creates a slight current. The first of these tunnels was built in Milwaukee, I think, something like twenty years ago. A second one was added fifteen years ago. And a third and a more expensive one has just been recommended, as the conditions in parts of the stream are bad at the present time.

Q. Have you, from your investigation, an opinion as to what such a system would cost, if it were to be constructed and put in use in the Calumet River, assuming that the channel proposed is not built and the sewage became a nuisance in the river?

A. The first two tunnels and works at Milwaukee cost approximately $750,000. They have served their purpose well, but seem to be outgrown at the present time. The estimated cost of the canal recently recommended is about $1,150,000, which would bring the whole cost of the works to $1,900,000. Taking into account the fact that the two canals as built seem to be somewhat overtaxed, and the fact that the new canal anticipates growth, three dollars per capita for construction seems to be about a fair figure. And the cost of operation, which is made up mainly of pumping water, at Milwaukee seems to run from ten to fifteen cents per capita per annum.

Q. In your opinion, would those figures prevail substantially in the Calumet region if the same system were employed?

A. Why, I should suppose they would within certain limits. Of course tunnelling conditions may be more favorable or less favorable. I have not looked into that. It was my

feeling that what Milwaukee had actually spent was perhaps the best off-hand guide that I could get as to what Chicago might reasonably spend in this case.

Q. And in your opinion that is a good guide?

A. Yes, in a general way.

Q. Taking into consideration, Mr. Hazen, the fact that the Sanitary District has thus far proceeded to dispose of the sewage of the district by the dilution method and by the construction of channels, I want your opinion as to the advisability of either changing the system or attempting at this time to supplement the works that are already constructed by an entirely different system; and if such attempted substitution or addition were made, what would be the effect on the present sewerage system of Chicago; the costs and difficulties involved; not having in mind the figures at all, but the general wisdom of the substitution or change?

A. I think it would be very unfortunate to have to change the system at this time. The whole theory of the present system, as I understand it, has been to dilute the sewage matter as promptly and as largely with water as possible. To treat the sewage so as to purify it artificially in a chemical way involves carrying out the reverse system; that is, treating the sewage matters with as little dilution as possible up to the point where the sewage is treated. The whole district is sewered on the combined system; that is to say, all the rain water and street wash is carried to the sewer and flows in the same channel with the sewage matters. To completely and economically treat the sewage, it is necessary or at least very desirable to have the separate system; that is to say, to keep the sewage matters from mixing with the street wash and rainwater.

In order to treat the sewage thoroughly, adequately to its logical conclusion in any new district would mean the installation of separate sewers in place of the combined sewers, and this would involve a very great added expense. It is partly for that reason that it seems to me that a partial treatment of a larger quantity of sewage might have great advantges in connection with the present authorized flow rather than the complete treatment of all the sewage from a certain separated population. But certainly to change the system now would involve readjustments that would cost the district a great deal of money.

Q. If a separate sewerage system were constructed, in order to separate the sewage proper from the street washings and the rainwaters, those street washings would then flow

where, Mr. Hazen, assuming that this channel were not constructed through the Calumet region, and assuming that we are dealing with the Calumet region?

A. I presume that would flow to the Calumet River and ultimately to the lake.

Q. What effect would they have upon the purity of the water supply?

A. They would tend to pollute it.

Q. Will you state, Mr. Hazen, from your experience, what length of time it takes for fresh sewage to become putrified so as to become a nuisance?

A. I don't think there is a fixed limit on that. It is a question of temperature to a considerable degree. I can state my observations in going down the canal on May 23d as bearing upon this point. The mixture flowing in the canal after passing Western avenue must have been substantially the same that it was from that point all the way to Joliet; but in the upper part of the canal, that is to say, at Western avenue and for a few miles beyond, the sewage was comparatively fresh. There was plenty of dissolved oxygen in the mixture and the conditions were entirely unoffensive. Going down the canal, the amount of dissolved oxygen was steadily reduced and it was almost exhausted before the powerhouse was reached. The putrification of the sewage was apparent in the last miles; and there were evidently beginning to be deposits of sewage mud along the edges at several places, and especially in the fore bay at the power house. The mixture was almost up to the point of becoming offensive. This was especially interesting to me as showing the effect of time for these changes to take place. There was no increased pollution at the power house as compared with Western avenue of any practical significance, but there was a great increase in the effects of pollution.

The passage of the mixture by the power house partially aerated it, and considerably improved its appearance, so that it was in better shape below and in Joliet than it was right at the power house. Under the conditions of flow and temperature existing on this particular time, the greatest apparent effect of pollution occurred just above the power house. I can imagine, however, that with other temperature conditions, other conditions of flow, the maximum might occur at some other point.

Q. Suppose, then, Mr. Hazen, that the population of Chicago, that part of Chicago which sewers into the Chicago River, should substantially increase beyond the amount that

can be properly cared for by the dilution method according to the rate now prescribed by law, what would be your opinion as to the advisability of constructing a channel to discharge the water into the main channel at a point somewhere between Chicago and Joliet, for the purpose of further diluting the sewage as it proceeds down the channel?

A. It is my feeling that looking through a reasonable period of years, controlling points on the necessary amount of dilution will be at Joliet and in its neighborhood, and in the valley for some distance below; that through the closely built up part of the City of Chicago it is more a matter of time than a matter of dilution, and that with a sufficient current, meaning by that a current not less than the present current, the materials may be carried along—will be carried along so as not to become especially offensive in that part of the city, and with respect to these lower conditions, which it seems to me are going to be the controlling conditions in such a period of years, the mixture of water coming through this proposed Calumet Canal will be almost as useful as a corresponding quantity of water coming down the river all the way. Of course, if all the conditions permitted it, it would be better to have it come with the sewage all the way.

In speaking of the present current in the river, I referred to the current in the main stream. There is part of the North Branch where under the conditions on May 23d, the current was less than it ought to be; but there are new works under way that I understand will increase that.

Q. In your opinion, Mr. Hazen, is it desirable or necessary in order to properly treat sewage by the dilution method to have a current, so that the sewage is constantly in motion?

A. Why, yes, sir, I regard that as almost essential. If you have an extremely large dilution, it may do to put the sewage into quiet water; and on the other hand, if the available current is very strong, it is my feeling that the dilution may be a good deal less. I think there is a relation between the strength of current and the amount of dilution, and the stronger the currents, referring to the currents not only at the point of dilution, but all the way to the point where the sewage is disposed of, the dilution may be less than where the currents are sluggish.

Q. You have described your observations on May 23d, as to when you first noticed the putrifaction of the sewage. Can you state any more definitely how soon after you left Western avenue, that is, how short a distance from Western avenue, that condition first manifested itself?

A. It was manifest first in the chemical analysis in the determination of dissolved oxygen; that was going down steadily. But I can't say that I noticed much difference apparent to my senses until we had gone down the canal quite a long ways; and it increased most markedly within two or three miles above the power house.

Q. And what was the temperature on that day; that is, generally speaking, was it a warm day?

A. Yes, sir, it was a warm day.

Q. Would it make any difference, Mr. Hazen, in your opinion, as to where the point of putrifaction would become first appreciable to the sense as to what the temperature was; I mean having reference now to the chemical analysis?

A. I think it would. I think the temperature of the water would have more influence than the temperature of the air; and the highest temperature in the water would occur later in the season, in August or about the first of September.

Q. Would the putrifaction be noticeable—I am speaking now to the sense of smell—when it was warm sooner than when it was cold?

A. I should expect that it would occur sooner in the higher temperature. It is possible that to off-set that condition—I have observed that in Pittsburgh—where the discharge of certain kinds of manufacturing waste seemed to have the effect of stopping the putrifactive processes for the time being; and considerably postponing the point where the worst conditions appear; so the temperature does not necessarily alone control.

Cross-Examination by Mr. Wilkerson.

Q. Just what was the nature of the work which you did in the Lawrence Experiment Station?

A. We had experimental filters of various materials, of various depths, and to these we applied sewage, raw sewage, settled sewage and water of various kinds, in the endeavor to find out how sewage and water could be best purified, especially with reference to the conditions existing in the State of Massachusetts; and many other experiments along allied lines relating to the qualities of public water supplies and the methods of protecting them were carried out. It was an experiment station for the State of Massachusetts.

Q. It was for the purpose of finding out how much the water could be polluted and at the same time be taken care of by the filters?

A. Well, that is one line of investigation.
Q. Was that the principal line?
A. No, I should not say it was the principal line.
Q. What other lines were there?
A. The principal lines, that is your question?
Q. Yes.
A. They were to find the best available methods for taking care of sewage and water supplies in the state.
Q. And as the result of your work, was there any conclusion reached as to the best method?
A. Many important conclusions were reached. The work was not carried to the point of selecting any one method as being pre-eminent over others. That would hardly be possible, because there are different conditions that require different methods; and the work was rather to show what could be done by different methods under different conditions than to select one that was better than all others.
Q. Now, what was the nature of the plant that was constructed at Chicago during the World's Fair, which you spoke of?
A. That was a plant for treating the sewage by a process known as chemical precipitation. There is a description of the plant in the report of the Massachusetts State Board of Health for 1893, page 597.
Q. Give us just in a general way the main features of the plant and the method which was used?
A. The settling tanks were of the so-called Rockner-Rothe type. This was a German type tank which had recently been brought out and represented probably the most advanced practice and ideas at that time. There were four of these tanks. The sewage was first screened; then was treated with chemicals and went to the bottom of these tanks, the sludge deposited in the bottom; the sewage rose and overflowed weirs at the top and went to the lake. The sludge was drawn up from the bottom of the tanks from time to time; was pressed, and was burnt in a crematory near by.
Q. It was the intention that the sewage should be treated in such a way as not to pollute the waters of the lake, was it?
A. That in a general way was the intention.
Q. Was it successful?
A. The effluent, I think, produced no local nuisance around the discharge. So far as its effect upon water supply was concerned, the treatment might just as well not have existed.
Q. So far as the water supply was concerned?
A. So far as the water supply was concerned. In other

words, the treatment did not stop the bacteria representing any infectious material, which there might have been in the sewage.

Q. So it was more for the sake of getting rid of the offensive local condition that this was done?

A. That is what it accomplished. When you speak as to the intention, that goes somewhat back of my connection with the work. The World's Fair wanted to have everything up to date, and the best of everything; and they wanted a sewage disposal plant and they got it. I suppose that the people when they decided to build the plant expected that it would protect the water supply from any pollution that there might be in that sewage, but as a practical proposition it did not do that thing.

Q. Now, how many people did they have in mind in the construction of that plant as being taken care of?

A. The population tributary to the works is stated in the report mentioned on page 618. The greatest number of people was in October when there was a total attendance of 8,034,000 within the grounds.

Q. That is the whole month?

A. That is the whole month. In September there were 5,809,000. I could not say as to what number of visitors was contemplated in advance. This is a record of the number of visitors that there were.

Q. You say that the method which was used there did not result in destroying the bacteria?

A. It did not destroy them.

Q. It did not?

A. No, sir.

Q. Was it supposed that it would when the plant was constructed?

A. Well, I can't say as to that. The plant was authorized and started before I went to Chicago.

Q. Do you know how much the plant cost?

A. I, of course, knew from my experience at Lawrence that that method would not be efficient in stopping the bacteria. I doubt if many people in the department really knew that until they got the results. I can't tell you exactly what the plant cost; it is my impression it cost something like eighty to one hundred thousand dollars.

Q. What was the cost of operation?

A. Here I have it (referring to report). The cost of construction was $55,000; but I would say in regard to that that quite a part of the equipment was contributed as exhibits, so

that the fair cost of building it would have been considerably more than that.

Q. What would you say would be the fair cost of building it?

A. The machinery was nearly all contributed as exhibits. I think the figure I first gave you would be as nearly as I could tell you. The cost of operation from April 14th to October 27th was $14,207; 373,000,000 gallons of sewage were treated.

Q. Is that method used any more?

A. Yes.

Q. Where?

A. Providence, Rhode Island, uses it; the biggest sewage disposal plant in the United States.

Q. How long has it been in operation there?

A. I should think a dozen years, perhaps longer.

Q. Does this report to which you refer state that that did not result in destroying the bacteria?

A. It shows it.

Q. It is your report, is it?

A. Yes, sir.

Q. And the Providence plant was built after that time?

A. Yes, sir. I don't think the Providence plant was intended to remove the bacteria; I am sure it was not.

Q. What was it intended to do?

A. To keep the sewage sludge out of the bay.

Q. Is a plant of that kind in use any place else?

A. At Canton, Ohio, they have a plant of that kind, that I think is in service. Worcester, Massachusetts, has a plant of that kind; but in the last years, the greater part of he effluent from it has been subsequently filtered; but the chemical precipitation part of the plant is still operated. Plants of this description were used very generally in Europe at this time. I think it was the most widely used method of treating sewage at that time, perhaps in the whole world.

Q. At that time was it generally supposed that that method would destroy the bacteria?

A. It certainly was not in Europe, because the European plants as far as I know were not any of them intended to remove the bacteria. They were intended to remove the sludge which otherwise produced objectionable deposits in the rivers and channels; and the European engineers and chemists that I knew in charge of these plants were under no illusions in regard to their lack of bacterial efficiency.

Q. You say you studied in Dresden for a year or two?

A. No, for a semester—a term.

Q. Along the same general line of work that you had been doing at the Lawrence Experiment Station?

A. I took the course of Wasserbauer as they call it, water works construction, hydraulic construction.

Q. Now, you have spoken of some plants with the construction of which you have had something to do. You spoke of one at Altoona, Pennsylvania?

A. Yes.

Q. What kind of a plant have they there?

A. That was what was called intermittent filtration of sewage. A large sandy tract of land was taken and cut up into beds and underdrained; and the sewage is applied to that during the summer and crops are raised upon it, so that it is a partial irrigation.

Q. For what sized population was that plant intended to provide?

A. The population of Altoona, as I remember, is forty or fifty thousand, and this plant serves rather more than half the city. The other half of the city drains in another direction to another stream.

Q. What did that plant cost?

A. I should have to look up my records.

Q. Have you any general idea on the subject? I do not care for the exact figures.

A. Well, I should think $100,000.

Q. And what would be the cost of maintenance?

A. Well, probably $1,000 a year.

Q. And in order to provide for a larger population, would the cost be proportionately greater?

A. It would be if there was more sandy land, but we took all the land there was available.

Q. You have to have sandy land?

A. You have to have sandy land in order to do it.

Q. If you have lots of sandy land that kind of a plant works all right?

A. That plant worked all right. That is why substantially the same kind of plant has worked so well at Paris and Berlin.

Q. So if you had whole counties of sand that could be put in operation very easily?

A. That would be first rate, barring the transportation. I may say in regard to this Altoona plant, it is intended to treat the sewage in summer when it is otherwise objectionable in the stream. The process does not work very well in winter and I have never considered that it was necessary to treat

that sewage in the winter, and have advised them to bypass the plant and let it go through the winter.

Q. What kind of a plant was put in at Spencer, Massachusetts?

A. That was similar in its general character to Altoona; treated the sewage of the whole town. The sand was coarser and better at Spencer than Altoona.

Q. Was that as large a plant as the Altoona plant?

A. Not as large in area; not as large in any way, because the population was smaller.

Q. Was the plant at Plainfield the same kind?

A. That was, but Plainfield has grown rapidly and the sandy area not having grown, the plant has been rebuilt and modified since I had to do with it.

Q. You say you have acted in an advisory capacity to the City of Pittsburgh?

A. Yes.

Q. During how long a time has your employment continued?

A. I took that work up a year ago last January.

Q. Did they have in contemplation there the construction of a new system, or was it with reference to overhauling the old one?

A. It has been proposed to reconstruct generally the sewer system of Pittsburgh, with the object of taking the sewerage to one place and treating it before discharging it into the Ohio River. The whole question of the expediency of doing that and the methods to be followed, is being investigated.

Q. Has any conclusion been reached on that subject?

A. No conclusion has been reached.

Q. Have you reached any conclusion?

A. Not officially; I have personally.

Q. Well, without committing yourself in any way that would prejudice your employment there, just what are the available methods of handling the sewage?

A. I can tell you what the available methods are.

Q. I suppose what it is desired to accomplish is not to pollute the waters of the Ohio River?

A. Yes.

Q. To save the water in the river from that pollution?

A. Yes.

Q. So that the sewage will be treated before it reaches the river, so that it will be inoffensive?

A. That is the idea.

Q. Now, what is the general scheme that has been worked out with respect to that?

A. Several general schemes have been worked out.

To go back to your preceding question as to what the possibilities are, there is first the possibility of the present conditions where all of the sewage collected in the combined system and mixed with all the rainwater and street washings goes to the river at the nearest point. The first possibility of improvement consists in taking the dry weather flow from the larger sewers and taking it through settling basins to remove the heaviest part of the sewage mud and to prevent the deposit of sewage mud in the shallow water along the shore of the river at low water, especially between the shipping and the shore. That method of treatment is directed to correcting the physical appearance of the river opposite the city. That is the method that is usually used by cities in continental Europe. It has not been adopted in America to any appreciable extent. It is not directed at all to protecting the river water below from pollution with respect to water supplies.

The next possibility that may be mentioned consists in the collection of all the sewage at some central point where it might be treated and purified before being discharged. This involves in the first place installing a separate system throughout the city in place of the combined system, at a cost of untold millions of dollars. It is a very expensive operation and it is absolutely essential because no plant can possibly be built that is capable of carrying off the storm overflows from a city like Pittsburgh. The storm overflows from Pittsburgh are larger in proportion than in Chicago because the topography is abrupt and the run-off is quicker.

After the present sewers were all built over on a separate system, then great intercepting sewers would be built down each side of each of the main rivers to some central point, or some point below the city, rather, where a site may be selected, and where the sewage would be pumped to bring it from the low level which it had reached by its gravity flow up to an area where the disposal works would be built, above ordinary floods; and there works would be built on some system to purify it.

Q. Aside from the cost of reconstructing the system of sewers, have you reached the point of making any estimates, as to the cost of the purifying works?

A. Such estimates are in process of being made, but I am not in position to announce any results as yet.

Q. Are you able to give us a general idea as to the limits within which the cost of such a work would fall?

A. It represents a great many million dollars.

Q. Are you able to give any more definite an estimate than that?

A. No, I could not state it any more definitely.

Q. When you say a great many, do you mean more than ten?

A. The whole plant represents a good deal more than ten.

Q. I am speaking not of the reconstruction of the sewers but simply the purifying plant itself?

A. I could not state as to that.

Q. How large a population are you attempting to provide for?

A. The present population is about a million.

Q. How much growth are you anticipating in planning the plant?

A. We laid these works out for about double the population.

Q. About two million?

A. Pittsburgh is growing quite rapidly.

Q. You could not give an approximation, or what you believe such a purifying plant would cost to construct?

A. No, I could not. I could give you corresponding figures for Paterson, New Jersey.

Q. Let us have those?

A. Where the estimate was completed?

Q. For how large a population were you attempting to provide there?

A. The population of Paterson in 1905 was assumed to be, at that time, 111,000. The population contemplated in the estimates was 250,000, of which a part of the construction was to be postponed. The whole cost of the purification works was estimated at $3,028,000, of which $600,000 could be postponed for a time; and the cost of the works to be built at once was $2,428,000. That does not include the cost of separating the sewers. Paterson was sewered on the combined system, and this estimate did not contemplate an immediate and complete separation, but only the separation of the larger areas at once, to be followed up with a gradual separation of other areas. I find that I allowed $550,000 additional for separating surface drainage.

Q. I think you said you came in contact with this Chicago problem in the litigation between the Sanitary District and

the City of St. Louis, with reference to the pollution of the water?

A. I did.

Q. You were a witness for the City of St. Louis?

A. I was.

Q. And then had occasion to look into the effect of the discharge of sewage through the Drainage Canal, down through the Illinois River and into the Mississippi?

A. Yes, sir.

Q. And what conclusion did you reach about that?

A. I reached the conclusion that the sewage of Chicago was an undesirable addition to the St. Louis water supply.

Q. That was before it was treated?

A. The water was used as it came from the intake at that time.

Q. That was at St. Louis?

A. That was at St. Louis.

Q. That is to say, you reached the conclusion that the effect of the taking of this sewage from the Chicago Drainage Canal down through the Illinois and Mississippi Rivers polluted the water supply of St. Louis?

A. I believed it did. It certainly tended that way.

Q. It was your conclusion as an expert in the case that it did have an effect of polluting the water?

A. I believe it did.

Q. That was the effect of your testimony, was it not?

A. (No response.)

Q. Now, you have had to do with the construction of a plant at Washington, did you say?

A. For treating the water.

Q. Treating the water?

A. Yes, sir.

Q. What is it necessary to do there? What was done; just what was the plant constructed there?

A. The water is taken from the Potomac River. It flows from an intake above Great Falls through three reservoirs in which a considerable amount of mud is deposited. Before the plant was built, it was pumped directly from the last of these reservoirs into the mains, or flowed to some of the lower parts of the city by gravity.

The plant is a plant for filtering the water. It consists in passing through sand; the water is pumped from the last of these reservoirs to twenty-nine filters of sand and covered with masonry structures; and the water passes through the sand and is collected underneath and carried through suitable

works and conveyed to the distribution. The works are similar in their general nature to those which I suggested being used in treating the Chicago water, in case sewage were discharged in large quantities into Lake Michigan; but differ in many details because the Potomac water is different in its character from Lake Michigan water, and requires within certain limits a different kind of plant to handle it.

Q. Was the problem there a more difficult problem than the Chicago problem, assuming all the sewage was discharged into the lake?

A. Yes, I think it was.

Q. It required a more expensive plant than would have been required at Chicago?

A. More expensive per million gallons, yes; of course, not as large, not as expensive in the aggregate because Washington is not as large as Chicago.

Q. And for how many people did you undertake to provide in the construction of that plant?

A. Oh, we figured it to provide so many million gallons. The question of how many people depends upon how many gallons per capita they use.

Q. How many million gallons did you have in mind?

A. The consumption at Washington has decreased a good deal in the last years by cutting off useless waste, and the consumption is a good deal less now than it was when we first took this work up. The plant was built to treat eighty-seven million gallons of water per day, but it is actually capable of treating a somewhat larger quantity.

Q. Do you know how much that plant cost?

A. It cost about $3,300,000. That is a higher cost per million, no doubt, than I figured for Chicago, because, as I stated, the conditions are different and at Chicago I assumed that we should use a rate of 6,000,000 gallons per acre daily, which is the rate that we are proposing to use at Toronto and they actually use in some other cases.

Q. You are speaking of some estimates that you made for Chicago; when did you make them?

A. In this testimony. The Washington filters were only designed to operate at half that rate.

Q. Now, with reference to this study of the lake and river conditions at Chicago, which you made last week, at the time you made this study, how much water was being diverted from Lake Michigan through the Chicago River?

A. The quantity as calculated at my request from the

records available on May 23d was 421,311 cubic feet per minute.

Q. You spoke with reference to the amount authorized by the law of Illinois as 20,000 cubic feet per minute for each 100,000 inhabitants, and with reference to the reasonableness of that amount. Now, on the basis of the present population of the City of Chicago, how many cubic feet per minute were being diverted from Lake Michigan through the Drainage Canal, at the time you made these observations?

A. I took the population as 2,200,000, which was obtained by taking the population by districts according to the census of 1910, as Mr. Pearse worked it out, and adding the estimated normal growth for one year; and it came a few short of that, but we rounded it out, and it was 2,200,000. That would make 19,200 cubic feet per minute per 100,000 of population. I regard these as approximate and not exact figures.

Q. Did I understand that you had made an estimate of the cost of constructing the plant for treating the water supply of the City of Chicago on the basis of its present population?

A. Yes, sir.

Q. And what was the figure which you gave? This is assuming, of course, that all the sewage goes into the lake, and the water has to be treated?

A. Assuming that the sewage from an added population of 1,200,000 goes into the lake?

Q. No, I am speaking now of the cost of treating the sewage on the theory that it was all emptied into the lake, and that you closed up the present channel.

A. I have not made such an estimate.

Q. You have made no such estimate as that?

A. No.

Q. You made an estimate of the cost of treating the water supply on the theory that the sewage from 1,200,000 goes into the lake?

A. Yes, sir.

Q. Would it require a very much more expensive plant to treat the water supply, if the sewage from two and a half million went in rather than 1,200,000?

A. Well, that would depend largely upon the points that were available for the discharge of the sewage. It would be much more difficult and more expensive to get outlets for the sewage with the larger population which would be as well diluted and no more injurious to the water supply than it would to secure such outlets for a million two hundred thou-

sand population, which population naturally would be extra population and largely at the extremeties of the city as distinguished from the central part of the city.

Q. This computation which you made was on the theory that this 1,200,000 population is in the neighborhood of the Calumet River. What I am trying to get at is the exact elements that have entered into that computation?

A. I assume that it might all enter from the Calumet district, or that any part of it might enter from a somewhat similar district to the north, where it might be more convenient to let part of the sewage go.

Q. And you have made a computation on the basis of the sewage of 1,200,000 people?

A. Yes, sir, that is to say, I assumed that that amount of raw sewage was going into the lake.

Q. And have you made a computation having in mind the present approximate population of this Calumet district? What is that figure?

A. The estimated population now connected with sewers discharging into the Calumet River is 131,000; that is wholly within Illinois. And in addition thereto there are about 50,000 people in Illinois not connected with the sewers, on the best available data; and in Indiana there are estimated to be 97,000 people.

Q. Now, let us assume that this canal here connecting with the Calumet River is not permitted to be constructed, and that the sewage which is now going out through the Calumet River has to be provided for in some other way. Having in mind, we will say, that the population of the district is double what it is now and allowing for that element of growth, just what could be done in the way of taking care of the sewage of that district?

A. I should say that the first step would be to filter the water supply.

Q. That is to filter the entire water supply of the City of Chicago?

A. I should say so, starting perhaps with the south crib and working north.

Q. Well, wouldn't it be possible to treat the water that empties into the lake in some way so as to render it inoffensive?

A. Treat the sewage, you mean?

Q. Treat the sewage, yes?

A. It would be possible to do that, but in my judgment it

would cost more money and be less efficient than treating the water.

Q. How could the sewage be treated? I am speaking now of, say a population of 300,000 people, assuming that there were 300,000 people around that river?

A. It could be treated as was proposed for Paterson and as has been done at Columbus and other cities, by collecting it in intercepting sewers, by pumping it, by settling out the heaviest of the sludge, by screening it, by applying it to sprinkling filters; by settling again the effluent from the sprinkling filters to cut out the heaviest part of the mud, and finally by disinfecting the effluent with hypochlorite of lime. All these processes are successive processes, not alternate ones.

Q. What would be the result assuming that method were followed as to the condition of the water which would go into Lake Michigan?

A. If all the processes were carried out perfectly, and if all of them worked all the time, it would remove very much the largest part of the organic polluting matters, and the largest part of the bacteria, but it would not remove all of them.

Q. Would it then be necessary to filter the water?

A. I should say so.

Q. That is, you think even if that method were resorted to, you would still have to filter the water, at least from the Hyde Park Crib?

A. From the standpoint of water supply, I should make very little difference in the required treatment whether the sewage was treated before discharge or were not so treated. In other words, I do not believe that the methods of sewage treatment now available in a location of this kind are to be fully relied upon to protect the water supply.

Q. In the estimate which you made, you had in mind the population of 1,200,000, that is, the sewage from a population of 1,2000,000 people?

A. Yes.

Q. Have you made any estimate of the cost of filtering the water, assuming that the sewage of only one-fourth of that number of people emptied into the lake?

A. No, sir, I have not.

Q. That is 300,000. What difference would that make in the estimated cost of filtering?

A. It would not make a very large difference.

Q. Would it reduce it?

A. It would tend to reduce it, yes.

Q. Would there be the same necessity for filtering the entire water supply of the City of Chicago if the sewage of 300,000 instead of 1,200,000 emptied into the lake?

A. There would not be the same degree of need of filtering, certainly.

Q. Would you have to go any further north, in your opinion, than the 68th street crib, if the sewage of only two or three hundred thousand people emptied into the lake, in filtering the water, or would it be sufficient to simply filter the water that was taken in at that crib? I am assuming now that all that goes into the lake is from the Calumet District?

A. Yes.

Q. Instead of 1,200,000, you have only two or three hundred thousand people?

A. Discharging here (indicating on map)?

Q. Discharging there, and that is all that goes into the lake?

A. Yes.

Q. And having in mind that the water supply is taken from different places all along the lake shore. I am trying to get your best judgment as to how much of the water supply you would have to filter, on the basis of two or three hundred thousand people in that territory?

A. It is clear that all of the water ought to be treated, but it may be that from the northern tunnel water would be obtained which for the present would be of sufficiently good quality with simply the hypochlorite treatment carefully administered; and that might be true of some of the other tunnels, with the smaller population.

Q. That is, you think that with the hypochlorite treatment you could on the basis of merely two or three hundred thousand people, down there discharging sewage into the lake, you could remedy the difficulty with respect to a considerable portion of the water supply?

A. It would improve the situation very much, certainly.

We have found that at Toronto where unfortunately there was a break in the intake during the last winter, and where temporarily water has been taken of much more polluted character than is ordinarily used, we have found that by following out the hypochlorite treatment very persistently and carefully, the results have been very satisfactory.

Q. Now, with respect to this water at the 68th street crib, you went out you say with a chemist?

A. No, sir, I did not go out to the 68th street crib.

Q. Just what examination did you make of that water?
A. I only examined the records of the Health Department at this time.
Q. That was on the 23d of May?
A. Yes.
Q. And the records which you saw showed what with reference to that water at the 68th street crib?
A. The greater part of the time the water is of as good quality as the water from the other tunnel, but occasionally it falls off in quality very much, so that it cannot be considered good water.
Q. How much of the time is that?
A. I cannot state the extent of the time. That is a matter of degrees. It falls off a little in quality for longer periods, and falls off a great deal in quality for shorter periods.
Q. Of course there are always some bacteria in all water, and it is a matter of degree as to when the water is safe to drink?
A. Yes, that is true.
Q. It is hard to fix the absolute limit, where we know that water is safe to drink. It is difficult to get absolutely safe water?
A. I should say there was such a thing as absolutely safe water, practically safe.
Q. What I was trying to get at was, in as specific form as we could get it, just what and to what degree there is anything wrong with that water there at the 68th street crib?
A. This pollution is most effective when the wind blows the water directly in that direction. (Indicating on map.)
Q. That is north?
A. Yes. They tell me that at the Health Department; but I also know that from my experience with lake waters in other cases. The wind may blow it up here (indicating) on one day, so that it comes up and there is a good deal of pollution, and then the next day the wind may blow from some other direction and the water is of quite different quality. It is possible for the character of the water from a lake intake of this kind to entirely change its character in a half hour.
Q. When you spoke of the wind blowing, you meant blowing from the Calumet River?
A. Towards the intake.
Q. North towards the intake?
A. Yes, sir. I do not know as I completed the answer to your question.

Mr. Wilkerson: Pardon me.

The Witness: Having seen these records and knowing something of the pollution of lake waters and their subject to these influences, I can put it this way: If I lived in territory served by that intake, I should not want to drink the water without having it boiled.

Q. Or filtered?

A. Or filtered, yes, sir.

Q. Now, has it not been considered possible to take the sewage of this Calumet region here and dispose of it in some other way than by discharging it through the Calumet River, or have you given any consideration to any such plan as that?

A. I considered the possibility of collecting this sewage and treating it in the way that I mentioned a few minutes ago, and it certainly could be done. Treating the sewage of Milwaukee in that manner was considered by the Commission of which my partner was a member, but it was found on the evidence that they had that it was clearly better to discharge the sewage at selected points into the lake and filter the water. And at Toronto the question of purifying the sewage in some such manner was considered, and very carefully considered at great length, and the decision was reached there to discharge the sewage at one point after the removal of only the heaviest of the sewage mud by settling, the removal of which does not make any difference whatever with the bacterial conditions, and filter the water.

Q. Now, as to the cost of filtering the water supply for the City of Chicago, your estimate was on the theory that the sewage from a population of 1,200,000 discharged into the lake?

A. Yes.

Q. I do not recall the final figures which you gave, but in order that I may get my next question, just state what that estimate was?

A. $13,000,000 for the construction and land.

Q. $10,000,000 for the construction of the plant and an estimated cost of $3,000,000 for enough land on which to operate the plant?

A. Yes, sir, and the operation in addition.

Q. And the expense of operation was in addition to that. Now, if the Drainage Canal had never been built, the sewage from the entire population could have been handled in the same way, could it not?

A. I think it undoubtedly could have been, though it would have involved no doubt, the carrying the sewage some dis-

tance to get proper points of dilution for so large a quantity; and also carrying the waterworks intakes to a considerable distance, preferably in some other direction, to get as far away as possible from the sewage.

Q. I think you said you had made no study of the situation with a view of determining what it would cost to dispose of all the sewage, on the theory that the Drainage Canal was entirely closed?

A. No, sir, I have not attempted that. I started with the assumption that the Drainage Canal was a fixed fact; with 10,000 cubic feet of water that could be diverted through it.

Q. Of course, if they had 10,000 feet of water which could be diverted through the Drainage Canal, that would still take care of a good many more people than are in Chicago now?

A. On the basis of the legal rate, it would take care of 3,000,000 people.

Q. Then it is your judgment that at an outside expense of $13,000,000 it is possible to construct a filtering plant, which would insure the purity of the water supply of Chicago, upon the assumption that the sewage from a population of 1,200,000 people was discharged into the lake?

A. Yes, sir; that is for the present quantity of water. Of course, as I stated, if they draw more water in the future, that it would increase approximately in proportion to the quantity.

Q. That would be something that would be controlled by the growth in population?

A. Exactly.

Q. And with respect to the cost of filtering the water supply, you are quite clear as I understand it, that if you reduce the population from which the sewage goes into the lake, so that you have the sewage of only two or three hundred thousand people to provide for, as is now the situation in the Calumet District, the expense would be less even if you filtered all the water, and it would be very considerably less in case it were found necessary to filter only the water from certain cribs?

A. So far as it might be found unnecessary to filter the water of certain cribs, there would be obviously a corresponding reduction in cost, but if the water were filtered at all, reducing the amount of population providing sewage would not very greatly reduce the cost of filtering. In other words, the filtering that I have in mind for the conditions that I have stated, represents approximately the minimum cost of filtering.

Q. At the risk of perhaps repeating something I have already asked you, would you think the cost would be very materially greater, in case you undertook to filter the water on the theory that you had the sewage from 2,400,000 emptying into the lake, that is, double the 1,200,000 which you had in mind in the preparation of the estimate about which you testified on direct examination?

A. My feeling is in case the sewage canal were obliterated and all the sewage of Chicago were discharged, that the costs involved in taking care of the sewage and water so as to get a good water supply with filtration, would be very greatly increased. I do not think that a large part of the increase would be represented by the increased cost of filtering, but I do think that there would be a very great expense required to take the sewage to appropriate points of discharge far enough off shore to prevent the production of local nuisance, and separated from the waterworks intakes; and to build the longer intakes that would be necessary, and the intakes located away from the sewage outlets; and the land tunnels that would no doubt be necessary in connection with them.

That is to say, of course, I can't say what the scheme would be off-hand, without further study, but in case you threw the canal over and said you would treat the whole sewage of Chicago by dilution in the lake, very likely you would build a big intercepting sewer and take the whole sewage of the city down to some point on the south side and discharge it through a series of outlets going away out into the lake. And you would give up these south waterworks which are near them and perhaps the waterworks up here (indicating) near the mouth of the old Chicago River, which is a dangerous element, as soon as its natural flow is returned to the lake. And you would take the water, perhaps, for the whole city from some point up off Evanston and filter it at that point at one big station, and send it through a great big tunnel going down through the city away to the south side.

Now, I do not say that is what you would do. You might study the thing out and do something very different from that, but whatever it was, you would spend millions and millions of money in solving the problem adequately in that way.

Q. But you have a feeling now that under conditions as they now exist, and in view of the stage which has been reached in your profession, that it would be possible to deal with the sewage situation in the City of Chicago eliminating the Drainage Canal entirely and have good water?

A. It could be done, yes.

Q. Have you made any study of the system that is used in London?

A. The water supply or sewage?

Q. The sewage, disposal of sewage?

A. I have visited the London works, yes.

Q. How do they dispose of it there?

A. It is collected, except storm overflows, in intercepting sewers on either bank of the Thames. On the north bank it is carried down to a place called Barking; on the south side down to a place called Crossness. At those points the sewage is carried through large settling tanks in which the heaviest part of the sewage mud is removed by settling. The sewage is all pumped, I think, before it goes to the settling tanks, and it flows from the settling tanks into the Thames, which, of course, is tidal at this point.

The sludge from the tanks is loaded into steamers, tank steamers, and carried out to sea and dumped. Chemicals have been used at times in the treatment of the sewage so that the process is a chemical precipitation, and directly comparable with that which we mentioned in connection with the World's Fair at Chicago.

Q. Does the problem of the disposing of the sewage in London have anything to do with the water supply, the purity of the water supply?

A. Absolutely nothing.

Q. They are two entirely different problems?

A. Entirely different.

Q. What are the principal cities in which the disposal of the sewage and the water supply become parts of one problem, so that you have to have the disposition of the sewage in mind in dealing with the question of the purity of the water? I am speaking now of the principal cities?

A. The disposal of sewage is a matter of importance to all cities that take their water supplies from rivers receiving sewage above, but there are very few cases where sewage has been purified prior to discharging into such rivers, for the sole or principal object of purifying a water supply taken from the stream below.

Where water supplies are taken from small catchment areas with storage reservoirs as distinguished from large rivers, the problem is somewhat different. There the whole of the run-off, or a large fraction of it, is used for water supply, and the sewage discharging into the water is oftentimes more important relatively.

Boston, New York and many other cities are supplied in

this way. These cities have made efforts to have the sewage from the towns on their catchment areas purified. The towns involved are mostly small. The largest one that I think of is the City of Marlborough, certainly with not over 20,000 people. Boston and New York and some other cities have made persistent efforts to have the sewage from these towns purified, and they have paid the bills in connection with having it done.

There are many other cases where other cities have thought they would like to have it done; they have suggested it; sometimes taken legal means to bring it about, but without offering to pay the bills, and as far as I have heard the purification has not been accomplished in those cases.

In the Great Lakes, the sewage problem and the water supply problem are more intimately associated, in that the sewage and the water supply of the same city may become mixed, and in that respect differs from the river problem, where it is one town above another and the problem of sewage and water is one that almost all the towns on the Great Lakes have.

Q. Milwaukee is one of those?

A. Milwaukee has it, Toronto has it, Cleveland has it; Detroit and Buffalo have it, though in modified form, in much simpler form because there is a definite, strong current in front of them.

Q. Coming back again to the purification of the water of the Calumet before it empties into Lake Michigan, and dealing with that problem on the basis merely of the present population, or double the present population—I understand that is the population which you said you usually dealt with in problems of that kind; that is, you figured on about twice the population of the territory—I would like, if I can get it, as definite an idea as you are able to give us as to the approximate cost of doing that. I am proceeding now on the theory that if you do treat the water, there being the sewage of only two or three hundred thousand people emptying into the river, that perhaps will take care of everything except this 68th street crib, so that that would be the only crib the water from which you would have to filter. Can you give us anything like an exact idea of the expense of handling that situation in that way?

A. You are talking of filtering the water or treating the sewage?

Q. First of treating the sewage?

A. No, sir, I could not tell you about that. If the population of two or three hundred thousand were compactly placed

on the separate systems, it would be comparatively easy to approximate it; but this population is spread over a dozen miles, I should say, and there are various centers of population. There are manufacturing establishments here and there producing waste; and the matter of collecting the sewage and separating it from the storm waters and other flows with which it naturally mixes and which you build purification works for, would very likely cost a good deal more than the cost of the purification itself, and that is something I could not tell you off-hand.

Q. Could you tell what the works themselves would cost for a population of 250,000?

A. Why, I should say that the figures I gave you regarding Paterson were as good an approximation of that as I could give off-hand.

Q. That was about $3,000,000, wasn't it?

A. $3,000,000 exclusive of the cost of separating the surface water.

Q. A part of that, as I recall it, was an expense that could be deferred on account of the population being smaller?

A. Yes, sir.

Q. Now, then, have you given any thought to the cost of a filtering plant merely for the water that comes through the 68th street tunnel?

A. No, sir, I have not.

Q. Assume that one-third of the water supply of the city comes through that 68th street water tunnel, would the cost of building a filtering plant for that water be about one-third of the estimate which you gave for the whole supply? I mean do those figures which you gave run proportionately?

A. Generally they do. I think the real estate for the south one would be a little less in proportion.

Re-direct Examination by Mr. Williams.

Q. When you gave the figure of $500,000 as the annual cost of operating the filtration plant, did that amount include anything for depreciation of the plant?

A. No, sir, that is just the operating expenses, and that is made up of the cost of pumping the water to the filters; the cost of operating the filters themselves, and taking care of the grass, etc., that grows in the top; the cost of the laboratory and supervision and the cost of the final treatment of the effluent with hypochlorite.

Q. What would be a fair percentage of depreciation to figure in those plants?
A. I should say, off-hand, one per cent.
Q. Per year?
A. Yes.

Re-cross Examination by Mr. Wilkerson.

Q. They last a long while?
A. Yes, sir. I do not mean they last a hundred years, but one per cent. marked off for depreciation, I think, will take care of the wear and tear.

Subscribed and sworn to before me this ..... day of ....., A. D. 1911.

.....

June 1, 1911, 1:30 o'clock p. m.

Parties met pursuant to adjournment.
Present, same as before.

RUDOLPH HERING, a witness called on behalf of the defendant, was first duly sworn and testified as follows:

Direct Examination by Mr. Williams.

Q. Please state your name, place of residence and your occupation?
A. Rudolph Hering. My residence is Montclair, New Jersey; my business office in New York. My occupation is that of hydraulic and sanitary engineer.
Q. How long have you been engaged in the practice of your profession as a hydraulic and sanitary engineer?
A. Substantially since I graduated, 1867.
Q. Will you state in a general way the preliminary education and the experience that you have had in the practice of your profession?
A. I went to Europe and studied my profession at Dresden, Germany. When I came back, after a few engagements not exactly in the line of my present profession—I was then assistant in the construction of the parks of Brooklyn and Philadelphia,—I was engaged by the City of Philadelphia, m

native city, to make investigation on a new water supply for that city.

Q. Before we go on with your experience in the practice of your profession, I wish you would state what societies you are a member of professionally?

A. I am a member of the American Society of Civil Engineers; of the British Institution of Civil Engineers; of the Canadian Society of Civil Engineers; the Western Society in Chicago, and numerous others.

Q. Have you specialized on any particular line of civil and hydraulic engineering?

A. I have specialized since 1873—no, 1875, chiefly in sewerage and water supply engineering.

Q. Do you have any degree from any institution of learning?

A. I have an honorary degree of Doctor of Science of the University of Pennsylvania.

Q. Now will you continue your narration of your experience in a general way, especially with reference to your particular specialty?

A. I was assistant city engineer in Philadelphia, where I had charge chiefly of the sewerage work for some years. Then in 1880 I was commissioned by the United States Government to make a report on the sewerage works of Europe for the National Board of Health. I made that, and it is printed in the annual report of the National Board of Health for 1881.

Then I was engaged by the City of Philadelphia to make an investigation regarding a new water supply. The next engagement was by Mayor Carter H. Harrison in Chicago as chief engineer of the water supply and Drainage Commission, to ascertain what the City of Chicago should do with her sewage, and at the same time guard her water supply against pollution.

After that I was consulting engineer for the City of New York on sewerage work. Then I have been engaged in a number of cities in both water supply and sewerage, Boston, Philadelphia; recommended the present system of water filtration; also Baltimore, the present system of sewerage and sewage disposal; Washington's present sewerage system and also the present water supply filtration, in connection with other engineers; I was a member of a Commission that reported on those matters.

Then Buffalo, Cleveland, Toronto, Indianapolis, Atlanta,

New Orleans; and in all these cases both water supply and sewerage.

Then on the Pacific coast, San Francisco water supply and sewerage; Sacramento water supply and sewerage; Los Angeles sewerage alone; Tacoma, water supply; Victoria, sewerage; Winnipeg, water supply; Ottawa, sewerage.

Now we have the water supply of Montreal, at the present time, purification of the water supply of Montreal; Honolulu, sewerage and Santos sewerage and and water supply.

Q. Who are the other members of the Commission that acted with you in connection with the report which you made and the investigations which you made in connection with the disposal of the sewage in Chicago, and the protection of its water supply, in 1886, did you say that Commission was appointed?

A. Yes, sir. Mr. Benezette Williams and Samuel Artingstall.

Q. Mr. Artingstall was then the city engineer?

A. He was then the city engineer.

Q. As the result of your work, you prepared a report?

A. I did.

Q. And after the report was made, what, if anything, did you have to do with the legislation which was enacted by the General Assembly of Illinois, authorizing the organization of the Sanitary District?

A. I remember being a witness before the legislative committee.

Q. Your only connection with it was from the standpoint of engineering, and at the session of the legislature in 1887 you presented your veiws to the legislative committee?

A. I did.

Q. From that time to this have you in a general way kept informed as to the conditions in Chicago, lake conditions and conditions as to water supply and sewage disposal?

A. I have tried to keep myself informed in a general way. Having lived there, I had friends, and would stop over, and perhaps on other works, consultation and so on; and as one of my former assistants in Chicago was City Engineer, Mr. Erickson, I kept posted on his work very nicely. I also know Mr. Cooley very well, and also Mr. Williams, Benezette Williams, and in that way kept posted on the progress of the Drainage Canal. I went to see it during the construction; took a lot of European engineers over it during the World's Fair time, while it was under construction.

Q. During recent years, have you made any particular study of the situation as it has developed since the construction of the channel?

A. In 1906 I was engaged with my associate, Mr. George W. Fuller, by the International Waterways Commission to make a certain examination and report.

Q. That report you made and it was published?

A. That report was submitted on December 18, 1906, and was published as an appendix to the report of the International Waterways Commission, dated Toronto, Ontario, January 4, 1907.

Mr. Wilkerson: That is Appendix F?

A. That is Appendix F. Appendix A was the report that I made in January, 1887.

Mr. Williams: Q. Subsequent to the report that you and Mr. Fuller made to the International Waterways Commission, did you make any further detailed study of the situation with respect to the Calumet District and the Sanitary District, and make any report?

A. I did. At the request of Honorable Robert R. McCormick, president of the Sanitary District of Chicago, in the latter part of 1907, I made such a report, entitled: "Report on the Disposal of Sewage from the Calumet Subdivision of the Sanitary District of Chicago," dated October 15, 1907.

Q. Will you state in your own way, Mr. Hering, what different methods there are now successfully employed in the disposal of sewage, in a general way?

A. The most common method for large cities is a system by dilution, which means that the sewage is discharged into flowing water in a way to be thoroughly dispersed in it, and in such quantities that the oxygen dissolved in the running water is sufficient to oxidize the sewage matter.

The second way is to purify the sewage on land, according to several methods, depending upon the availability of land areas and certain kinds of land suitable for natural filtration, and upon other local conditions.

Q. Do climatic conditions enter into the consideration in any way?

A. They do. You can vary the system somewhat when you get into warm climates, generally in the way of economy. When you get into northern climates, you sometimes have to increase their cost by making your works perhaps larger or by preventing an injury to the works, relative injury to the works due to extreme cold weather.

Q. Taking into consideration, Mr. Hering, the fact that the Sanitary District has already constructed its main channel and has entered upon a plan of sewage disposal for the Sanitary District by the dilution method exclusively; and assuming that there is a capacity through that main channel to provide for the disposal of sewage by that method for a population of 3,000,000 people; and assuming that there is a large area on the south known as the Calumet District, a portion of which drains into the Calumet River which flows into Lake Michigan, a part of that area being sparsely settled; and taking into consideration the probable growth in population during the coming years, and the probable necessity to care for a population eventually of at least 4,120,000 in the entire sanitary district, what method of sewage disposal would you consider the most efficient and economical to carry on, for the added territory, and to provide for the added population at this time?

Mr. Wilkerson: Let this go in subject to the same objection that was made to the same line of testimony on the part of the witness Mr. Hazen on yesterday, without stopping to repeat the objection, either specifically with respect to this question or as to any other question; it may all be treated as going in subject to the same objection.

Mr. Williams: That is all right.

The Witness: It is my opinion that the proposed canal called, I believe, the Calumet Sag Canal, offers the most economical, and as I believe the most preferable method of disposing of the sewage of that part of Chicago.

Q. You prepared figures, did you, as to the cost of instaling other systems for the disposal of sewage for the Calumet territory?

A. I did.

Q. In the original plans that were suggested by you and your associates upon the Commission that was appointed by Mayor Harrison, was it contemplated at that time that the method now proposed should be carried out eventually?

A. It was contemplated; the matter was then seriously discussed, but our commission thought that it was a little bit distant to bring into the report at that time as regards details, because the money that we had was short anyway to complete the work that we had in contemplation for the built-up section of the city. And as you may know, the report that was issued was entitled a preliminary report with the expectation that we would make a final report. That was never made on account

of inability to get any further appropriation. His Honor, the Mayor, and his Council, stated that that preliminary report was entirely sufficient for them, and that they could proceed.

Q. In your investigation of the situation in the Calumet region and in the Sanitary District in general, did you have a report of the population and the growth of the population during the past numbers of years?

A. I did.

Q. The population curve, indicating the probable growth of the population?

A. I had prepared such data.

Q. From your investigation, aside from the dilution method what was the most economical method of disposing of the sewage of the Calumet district that you were of opinion was practical?

A. It was the method of purifying sewage on land to a degree which would make the effluent water non-putrescent. That method which we found to be the cheapest was one that we call the springling method, sprinkling filters, where the fluids, the liquids are sprinkled over beds of stone, coarse broken stone, and thus allowed to oxidize, and the solid matter which is previously settled out of the sewage is treated by itself, of course, in another way so that it would gradually rot out and constitute inoffensive solid material that can be used for filling or any other purpose for which material is used.

Q. How large an area of land would be necessary to dispose of the sewage by that method for a population of say 1,200,000 people.

A. It would require about 80 acres of sprinkling filters, and an additional area for tanks, and basins for sludge treatment, and for other purposes.

Q. Is any particular soil required for that kind of a plant?

A. No; no, it is entirely independent of the soil. The purification of the liquid is accomplished by oxidization in artificially prepared filters.

Q. You prepared an estimate of the cost of such a plant on the basis of a population of 300,000, which was regarded as being rather imminent, and an ultimate population of 1,200,000?

A. I did.

Q. Will you state the estimate of cost for both populations?

A. The estimate of cost for a population of 300,000 was

$4,761,000. The estimated cost of works for a population of 1,200,000 was $9,257,500. The annual cost of operation, and including interest on the investment, depreciation of machinery and so on for a population of 300,000 was $360,240, and for a population of 1,200,000 was $900,300.

Q. Did you separate, or have you the figures separate as to the annual cost of operation from the fixed charges of interest and depreciation?

A. I have.

Q. What was the annual cost of operation exclusive of the fixed charges?

A. For 300,000 population it is $139,000, and for a population of 1,200,000, $423,000.

Q. And at what rate per cent would you capitalize those annual expenses, in order to obtain a fund to perpetually maintain the plant?

A. I did not capitalize the annual cost, but I took an interest of 4 per cent. as the interest on the invested money, believing as we do, that a comparison between the cost of works is more in accordance with the actual condition if we compare the annual costs rather than the capitalized costs, which are more or less imaginary. I mean they are merely book figures; they are not real. They do not have to be expended.

Q. Since that report was made, have you given any further consideration as to the adequacy of the works that you have outlined in that report and of the figures that you have given to cover the cost of performing the work that you intended, expected would be performed by the works that you described in your report?

A. There has naturally been some progress made since then; and if I were to estimate the cost again today, I would increase it somewhat.

Q. For what reason and to what extent?

A. I would increase it because we are now able to treat the sludge in a manner so that there is no odor when it leaves the works, and for this additional advantage, I believe it is proper to pay an additional cost.

Q. Have you estimated any additional works in the way of treatment of the effluent?

A. I would also do that, which was not included in this estimate; that is a treatment with hypochlorate of lime so that the pathogenic bacteria that may escape from this rapid method of filtration would be destroyed, in the same way that we

now protect our water supplies, probably in much over a hundred cities in this country.

Q. In your opinion, in case the sewage of the Calumet district were disposed of by the sprinkler system and the effluent discharged into the Calumet River and from thence into the lake would it be reasonably necessary to treat that effluent with the method you described?

A. I should advise it today, because it is a fairly economical method and gives an assurance of protection against those diseases which are likely to be propagated by sewage bacteria.

Q. Have you made an estimate of what added cost would be involved in such treatment above the cost that was considered by you in making your report?

A. I have not; but I have reported such a method to the City of Oswego on the lakes; and also have been making some other studies for such treatment on the lakes; and I have made a general estimate.

Q. Will you give us a general estimate which in your opinion, as near as you reasonably can, would indicate the additional cost that would be involved in the installation of such a process?

A. The cost would depend mainly on the amount of very fine suspended matter that is still left in the effluent sewage. This treatment attacks the organic matter in the sewage, and in order to be sure that it is also destructive of the pathogenic bacteria, we assume that it must be rather severe in order to prevent such bacteria from escaping together with the organic matter in suspension.

We therefore allow a much smaller amount for water that is clear, such as would be used for water supply than we do for water that is an effluent sewage, with fine suspended matter still remaining.

I have made, therefore, two figures, and would say that in the Chicago case it would depend upon the carefulness and thoroughness of the treatment as to which of these figures, or what figure between, would be proper. I will say that it would require per million gallons of sewage between 75 and 150 pounds of hypochlorite powder, which is the main expense.

Q. Is that sewage raw sewage or effluent?

A. That is effluent sewage, and treated merely by sedimentation, not filtration, or a high degree of purification. Of course, there is some labor required, so that I would say the

cost per million gallons of sewage would range from $1.25 to $2.50 in round numbers.

There is no allowance made in that for interest or depreciation in the works; nor for high grade intelligence such as chemists, which in a large city would be fairly small per million gallons.

Q. Do you know the average rate per capita per day of sewage that is calculated to be produced by people like Chicago people?

A. The quantity of sewage is usually estimated the same as the water supply, which I understand is 230 gallons per capita per day.

Q. Assuming, Mr. Hering, that works such as you have described briefly and referred to in your report, sprinkling filters, were installed, and the sewage of the Calumet district is cared for by that system, and the effluent treated as you have indicated it should be treated, would there be any difference in the cost of operation of such a plant in the winter months from the cost during the summer months?

A. There would. The activity of the bacteria in purifying sewage is much less in winter than in summer, and you would either get a less degree of purification or you would have to increase your plant correspondingly to get the same purification as in summer. And then it requires watchfulness. The sprinkling beds if not covered by a roof will have snow and ice upon them, and it is certainly not as simple to keep the filters at work. It would require possibly a larger number of men to keep the nozzles free and have things working right than in summer.

Q. Do you recall whether or not those considerations entered into the estimates that you made at that time?

A. I can't remember that we made—certainly we did not make a material allowance for winter conditions, with the thought, as I remember, that as time went along there might be some way of increasing the efficiency, although none was known to me at the time. But I did not care to load the estimates with something that I was not entirely sure of, particularly as it appeared that the sprinkling filter project was the more expensive one.

Q. Now, assuming that we have in operation the sprinkling filter system and a population of either 300,000 or 1,200,000 in the Calumet district; and the effluent is treated in the manner that you suggest; and that the system works satisfactorily, as well as such a system can be expected to work; the effluent is

discharged into the lake and treated in the manner that you have suggested, carefully and as efficiently as it can be, what is your opinion as to whether or not that method would be as satisfactory in disposing of the sewage of that territory as it would to divert it by means of sewers into a channel, the Calumet Sag Channel, and thence into the main channel of the Sanitary District and down the Illinois River, so that no part of it entered the lake?

A. As an engineer, I should certainly prefer the dilution method; and I think I should also as a citizen, because it is more simple. You do not depend on a number of factors that have to work together.

Q. There are human agencies you must depend upon, and mechanical contrivances and climatic conditions in connection with the sprinkler system, which would not affect the dilution method?

A. Yes. While I would not in the least be afraid that the sprinkling system would not give satisfaction, if I had the choice I certainly would try to get the results in a more simple way.

Q. The rate of dilution provided for by the present law of the State of Illinois is 20,000 cubic feet of water for each 100,000 of population, per minute. Assuming that there are no auxiliary works to treat the sewage before it enters into the canals and is subjected to the dilution process, what do you say as to the reasonableness of that proportion of dilution assuming no—

A. May I ask you what you mean by no auxiliary works?

Q. Namely that the sewage goes in in a raw state, without any treatment before it goes in, not any of the coarse stone treatment, no sedimentation, no tanks; it just goes in as it goes in now. Assuming it goes in as it goes now, what do you say as to that rate of dilution?

A. I am always on record, and I would like to be so now; and I believe in coarse screening under all circumstances.

Q. Assuming that there is not even that?

A. Then so far as a nuisance is concerned, other than to see large floating matter parading down the river, I would say this dilution was entirely satisfactory.

Q. Do you think that any less proportion would be sufficient, assuming that there were no screens and no auxiliary—

A. I think that dilution ratio that we stated in our report is the least that will give satisfaction.

Q. Assuming that the population of Chicago, the sanitary

district rather, should reach a figure whereby it would be impossible to comply with the provisions of the state law respecting the amount of water to be diverted from Lake Michigan, in proportion to the population, without exceeding the 14,000 cubic feet of water per second which we are contending for in this suit, has the science advanced any in recent months so that you are able to give us an opinion as to any auxiliary works that can at that time be established to increase the efficiency of the dilution method, and render it possible to decrease the proportion of water that may be necessary to accomplish the same results as are now accomplished by the entering of raw sewage into the channel?

A. There has recently, that is within the last few years, been developed in Germany a method of treating sewage where as in all other cases of land treatment it is endeavored to separate the liquid from the solid matter, which allows us now after separating the solid matter from the sewage, to allow it to decompose under water and with certain restrictions, in such a way that anywhere from three to six months after, according to climate, temperature, character of sewage, the solid matter may be taken out and then have no odor, so that a nuisance at the works is not created.

This makes it possible to have the separation accomplished in the midst of habitation, without offense, and the sludge removed without offense. This discovery makes it possible hereafter to remove from the sewage that portion which causes the greatest amount of nuisance, and thereby allow the liquid to be discharged into water with much less dilution than the legal rate, controlling the work of the Sanitary District. And therefore a possibility exists of increasing the amount of population correspondingly that may discharge into a river, without offense.

Q. If this method were employed throughout the entire Sanitary District, and the present impressions as to the success of this system are borne out, to what figure could you reduce the dilution?

A. I would say by a quarter to a third.

Q. What expense would be involved in the installation of such a system?

A. I have not figured out that expense, but I would say that experience in Germany, as applied to our American conditions, would indicate that the construction of these tanks would cost about $1.50 per capita.

Q. And there would be some cost of operation?

A. Then there would be some cost of operation, which would consist of pumping out the sludge into barges and carrying it away to a point of disposal, which of course I can't estimate, not knowing where it would go.

Q. Mr. Hering, if the problem of the disposal of the sewage of Chicago and its environs were now presented to you for the first time instead of in 1886, in the light of your experience since that time, would you make any different or other report with respect to the method of disposing of the sewage than you made at that time?

A. I would still recommend the dilution method.

Cross-Examination by Mr. Wilkerson.

Q. These three reports to which you have referred, Mr. Hering, are the ones designated as Appendix A to the report upon the Chicago Drainage Canal by the International Waterways Commission and Appendix F to the same report; the same appearing in the government print under date of 1907, and the report which you made to Mr. McCormick, the President of the Sanitary District, are they not?

A. Yes, sir.

Q. Those are the three reports?

A. Yes, sir.

Q. The one to Mr. McCormick is dated Chicago, October 15, 1907?

A. Yes, sir.

Mr. Wilkerson: I should like to have those reports identified, and I now reserve the right to read at the hearing in connection with the examination of the witness either those reports in full, or any part of the reports. What I want to do is to get the record in the same shape as if in connection with the cross-examination of the witness I had him identify each one of these reports, and had had the reports copied at length here, for the purpose of identification as his report.

Mr. Williams: For the purpose of identification?

Mr. Wilkerson: And I reserve the right in connection with his examination to read any part of the report in connection with his testimony that I see fit. The point is this: that when the deposition of this witness is read, I may read, if I see fit, in connection with his testimony, any statements in these reports, without putting questions to him right now and asking him whether he said this or that. It is to save time, that is all.

Mr. Williams: All right.

Mr. Wilkerson: Of course I shall contend that any statement which he made in any one of these reports is legitimate cross-examination; that is the statement should be read as cross-examination.

Mr. Williams: If you want to controvert any statement he makes in his reports—if you want to introduce the reports in evidence in your proof afterwards, in order to dispute something he said today, you can do that; or if you want to call his attention to any particular thing he said today, when he said something to the contrary before, and ask him to explain it, that would be all right.

Mr. Wilkerson: I am making no contention of that kind. He has testified on the general subject, concerning which he made prior statements. I could sit down and read these statements, and that would be proper cross-examination.

Mr. Williams: There are two ways by which you can take up any statement today that may seem to you inconsistent in any of these reports; the first is to call his attention to the fact he said so and so before and, what is your explanation of the inconsistency, if there be any. Or if you do not want to say that, you come in and say having said this before—

Mr. Wilkerson: I hardly think I am limited to that, Mr. Williams. All I want to do is to shorten the record.

Q. The first report, Mr. Hering, to which you referred in your direct examination is the first report which is designated Appendix A?

A. Yes, sir.

Q. It is under date of "Chicago, January, 1887". It is signed "Rudolph Hering, Chief Engineer, Benezette Williams and Samuel G. Artingstall, consulting engineers."

A. Yes, sir.

Q. I will ask you to look at the document which I hand you and state whether that is the report (handing witness document).

A. This is the report.

Q. I will ask you to read it.

Mr. Williams: I will object; it is improper cross-examination, and it is not a question put to the witness, but a direction to the witness, and the witness is under no obligation to read anything. If counsel wants to read anything or have anything read, he can do it himself *voire dire*. I object to having it shown that he is reading it into the record. I haven't any objection to his reading it for his own informa-

tion, in order that he may understand any questions you are going to ask him.

Mr. Wilkerson: I ask the witness to read the report and Mr. Williams objects to it.

Mr. Williams: Read the report into the record?

Mr. Wilkerson: Yes.

Mr. Williams: And I object to it, on the ground, first, that the instruction to the witness to read a document is improper, and is not in the line of cross-examination; that the direction is not an interrogatory intended to elicit any fact bearing upon the direct testimony that has been given; and that the witness is under no obligation to comply with any direction of counsel to read documents into the record, when such documents have not been introduced and have not even been offered in evidence; and counsel is not in a position at this time to offer testimony in his own behalf.

Mr. Wilkerson: Now, I say, with respect to that that the witness on direct examination has testified as to the making of a certain report. He has testified that at the time the report was made, he had in mind certain other things.

The report is called to his attention as the foundation for a line of cross-examination, and in order that the cross-examination may be intelligible, it is essential that the report to which he has referred and upon which the cross-examination appears may be in the record. As to whether the report itself is to be treated as a part of the cross-examination of this witness, to the extent that it becomes a part of the defendant's case, I am perfectly willing to let that question be reserved for the ruling of the court at the trial.

I think that on neither side will there be any particular difficulty if this report appears as having been read by the witness into the record as the basis for this cross-examination; the counsel for the defendant reserving his right that it shall not be treated as a part of his case; and leaving it for the Judge to decide whether the report is a part of the estimony for the defense.

Mr. Williams: I am perfectly willing that the witness be permitted to examine the report, read it fully; and that counsel may read it for his own information fully.

I object to the witness reading into the record any document or paper not offered in evidence. So far as identifying the document is concerned, there is not the slightest difficulty. It may be marked as an exhibit for identification and attached to the deposition, so that it may be hereafter offered

in evidence and made a part of the record, but I shall object to, and ask the witness to refuse to read into the record a document which has not been introduced in evidence in the case.

Mr. Wilkerson: In order that the witness may not be embarrassed by the comflicting directions of counsel, and in the absence of the court, I will direct your attention, Mr. Herring, to this report, Appendix A, which is as follows:

"Chicago, January, 1887.

To the Honorable Mayor and City Council of the City of Chicago:

Gentlemen: On January 27, 1886, your honorable body passed a resolution authorizing the creation of a drainage water-supply commision. After being amended, February 23, it read as follows:

Whereas pure water and scientific drainage are necessities of this community, and the people demand a system of water supply and drainage adequate to meet the requirements not only of the present, but of years to come, nor will any temporary expedient or makeshift satisfy them; and

Whereas a thorough and permanent system of supplying pure water to our citizens and caring for the drainage of the municipality can not be paid for out of current taxation, therefor it is desired that a plan shall be devised and perfected before the next meeting of the legislature to the end that necessary legislation may be had.

For the purpose of carrying into effect the objects sought, there is recommended the appointment by the Mayor of a commission to consist of one expert engineer, whose reputation is so high that his opinion and report will command the respect of the community, and with him one or two consulting engineers of like experience in engineering and sanitary matters. The duty of this drainage and water supply commission, made up as above set forth, should be to consider all plans relating to drainage and water supply which may be brought to its attention; to make such examinations and investigations and surveys as may be deemed necessary; to collect all information bearing on this problem; to consider all recent developments in the matter of sewage disposal, and their application to our present and future needs; to consider and meet necessity of increasing our water supply and of

protecting the same from contamination; to remedy our present inadequate methods of drainage and sewage disposal; to consider the relations of any system proposed to adjacent districts, and whether there may not be a union between the city and its suburbs to solve the great problem; to determine the great question as to the interest which the State and the United States may have in the disposal of sewage by way of the Illinois River, and to devise plans to meet any objections thereto, if such a system shall be thought best; and in general to consider and report upon any and all things which relate to the matter of water supply and drainage of the City of Chicago.

The commission should report on the whole matter committed to it in the most full and comprehensive manner, with maps, plans, and diagrams complete, and accompany the report with estimates of the first cost and annual requirements for the maintenance of the system proposed.

The report of the commission should be made as early as practicable, and not later than the convening of the next session of the Illinois legislature, in January, 1887.

In consideration of the foregoing, be it,

Resolved, That the Mayor be, and is hereby, authorized and directed to employ on behalf of the city one expert engineer of reputation and experience in engineering and sanitary matters, at a salary not to exceed $10,000 per annum, and also to employ such consulting engineers, not exceeding two in number, as may seem necessary, and such assistant engineers as may be required, all to be paid according to services rendered, for the purpose of carrying out the objects set forth in the preamble hereto. For the fees of said assistant engineers and for all expenses connected with said work there shall be allowed not to exceed the sum of $20,000. All fees, salaries, and expenses connected with said work shall not exceed in the aggregate the sum of $30,000, and the same shall be paid from the water fund of the city upon vouchers audited by the Mayor and city comptroller.

In accordance with the terms expressed herein his honor, Carter H. Harrison appointed Rudolph Hering as chief engineer, Benezette Williams and S. G. Artingstall as consulting engineers, who together should constitute a commission. Mr. Hering entered upon duty March 28,

Mr. Williams September 17, and Mr. Artingstall December 21, 1886.

The investigation designated by the resolution was a formidable one, composing no less a task than the consideration of the entire subject of the future water supply and drainage of Chicago. It appeared doubtful from the beginning that a report such as was demanded could be furnished within the specified time, for the simple reason, if for no other, that observations of the lake phenomena and of the flow of certain rivers should be extended over at least one year, covering four consecutive seasons, in order to draw satisfactory deductions.

But the large amount of work alone that was asked for made it impracticable to present a complete report in so short a time. It was expected, however, that results could be reached sufficient to indicate the character of legislation required to carry out any project that might be determined upon, and that therefore a preliminary report having this end in view could be made at the stated time, leaving to a later date the presentation of a report outlining the detailed features of the scheme recommended and embracing the minor results of the entire inquiry.

The present communication is to cover the ground indicated for the preliminary report, and besides containing the conclusions reached regarding the main features of the proposed project, it contains also a brief review of the work done during the past year and of what still remains to be done.

The month of April was devoted to a general examination of the subject of the territory to be investigated, and of the various suggestions that had been made toward effecting a solution of the problem.

The examination disclosed the fact that the city is sometimes greatly suffering from the offensive condition of parts of the Chicago River and its branches, caused by the discharge of sewage into the same, and from the occasional contamination of its water supply, brought about by the discharge of the polluted contents of the river into the lake. It also disclosed the fact that almost every conceivable way of dealing with these questions had been suggested and in some forms applied during the past thirty years.

The problem therefore demands the attainment of two ends—the protection of the water supply and the removal

of the river nuisance. As the water must be taken from the lake, it is evident that both its pollution and the objectionable condition of the rivers should be prevented by a better disposition of the sewage. It is, therefore, the latter question which constitutes the main object of this investigation.

Among the possible methods of getting rid of the Chicago sewage there are but three that have been deemed worthy of an extended consideration, namely: A discharge into Lake Michigan, a disposal upon land, and a discharge into the Des Plaines River. The preliminary work, has, therefore, been confined to these three projects, and was classed as topographic, hydrographic, and miscellaneous.

At the time when the present commission began its labors the topographical work had already received some attention. Surveys were being made of the Des Plaines River from Bridgeport westward under the direction of Mr. Artingstall, city engineer. These surveys were continued, and have now been completed as far as Joliet. They include contours of the entire valley and borings to rock between Bridgeport and Lemont. In order to understand the hydrography of the Des Plaines Valley above the point where the Chicago sewage could be discharged into it, and also to ascertain the probable magnitude and effect of floods in the river, a survey was made of its bed as far north as Northfield township. To determine the area of the basin its entire divide was located. To ascertain the practicability of diverting the flood waters from the upper portion of the Des Plaines and North Branch water sheds directly into the lake, and thus avoiding the difficulties which would arise from their passing through the Chicago River, all feasible lines were surveyed. Finally, a few levels were taken of the area adjoining the city wherever no connected levels existed to show the general topographical features of the territory over which the future city will spread out and from which the drainage will require artificial removal.

The hydrographic work consisted in ascertaining the flow of the Des Plaines River, the rainfall upon its area, its flood discharges, the character of its bed, and the probable effect of discharging the Chicago sewage into it when diluted by a large and constant stream of water from the lake. It consisted, further, in examining the

nature of the currents in the lake and in studying the rise and fall of its level, and in ascertaining the amount and character both of the sewage discharged into it and of the deposits in the river and lake in front of the city to determine the effects of the present sewage disposal.

Inquiry and surveys were made to show the feasibility of purifying the Chicago sewage by filtration on land. Land damages were carefully estimated for the different schemes; existing records were searched concerning borings and excavations made in and about the city, so that the practicability of certain lines of tunnels could be discovered; the probable growth of the city and its suburbs, as well as the probable distribution of the future population, received a careful attention, and, finally, a large number of data were compiled which pertain to the existing works of water supply and sewerage in Chicago and the adjoining towns.

In reporting the result thus far gained we will present them in the order most convenient for discussion, but before doing so will briefly describe the present manner and effect of the sewage disposal, as shown by this investigation.

Present Sewage Disposal.

The sewage works of Chicago and suburbs have been planned on what is called the combined system, in which the sewers serve for the removal both of sewage and rain water. In the town of Evanston they empty into the lake. In the town of Lake View they partly discharge into the lake and partly into the North Branch. From the north and west divisions and part of the south division of Chicago, the drainage enters the Chicago River and its branches, and from the remaining part of the south division it flows into the lake at three outlets, situated respectively, at Twelfth, Twenty-second, and Thirty-fifth streets. The sewers of Hyde Park discharge into the lake excepting those of Pullman, where the sewage is disposed of on land. The town of Lake, including the Stock Yards district, drains into the South Fork of the Chicago River.

When the sewage works of this city were designed, in 1856, by Mr. E. S. Chesbrough, it was apprehended that ultimately some means would have to be found to change the water in the river from time to time or to keep the

sewage entirely out of it. The first step toward improving the condition of the river was taken by deepening the Illinois and Michigan Canal, so as to cause a current from the lake to the Des Plaines River at Lockport. The next step was the building of the Fullerton avenue conduit in order to produce a circulation in the North Branch; and the last step was the erection of the canal pumping works to increase the flow in the river, which had become greatly polluted.

The influence of these works is confined to the main river and its north and south branches. But the south fork of the latter, receiving a large amount of sewage from Chicago and the town of Lake, and charged with the waste from the Union Stock Yards and packing houses, has no artificial means for a circulation of its water, and as a consequence is in a condition of great filthiness.

The accompanying diagram (a) has been prepared to show the present pollution of the Chicago River and its branches during the time when all of their water is discharged into the canal by the Bridgeport pumps. On the left are shown the main river and the north branch, one above the other, their combined waters forming the south branch, and reaching Bridgeport on the right, where they are lifted into the canal.

At the latter point the south fork is shown as joining it. The shaded portions indicate the amount of sewage entering and passing the respective points, and the blank portions the lake water diluting it. The degree of dilution is shown by the relative areas. It diminishes in the north branch from Fullerton avenue to the south branch, and becomes still less toward Bridgeport, and finally receives the foul waters of the south fork.

The depth and character of sewage deposits in the river and harbor, as might be expected, vary considerably. They are not great in the track of the vessels, but increase toward the docks and quieter portions of the slips, where they reach a depth of from one to four feet. While the deposits in the channel are of a heavier kind, such as cinders, those in the docks are mostly a foul mass of decomposing organic matter. No form of life is found to exist above Clark street bridge as far north as Clybourn

(a) Omitted; printed in House Ex. Doc. No. 264, 51st Cong., 1st sess.

place and as far south as Ashland avenue. The effect of this condition of the river is to endanger the purity of the water supply whenever the river, with its accumulated deposits, flows into the lake, which occurs when the rain water that finds its way into the river exceeds the amount pumped into the canal. If this excess is great, as in the spring and occasionally in the summer months, the contamination of the lake is considerable, and must constantly increase.

From the foregoing it is seen that the present method of disposal of the sewage from Chicago and its suburbs is partly by discharging it into Lake Michigan, but mainly, except during floods, by discharging it into the Des Plaines River.

Future Population.

The first question which requires an answer, and upon which many of the subsequent inquiries depended, was the population which it is economical and advisable to consider at present, and the extent of territory upon which such a population will be located.

The growth of Chicago has been frequently quoted as phenomenal. Estimates made thereof for various purposes have turned out to be rather under than over the actual result.

It is taken for granted that Chicago and its suburban towns will have to dispose of their sewage so that the water supply for the entire community residing near the lake from the south line of Hyde Park to the north line of Evanston will be guarded against pollution by the sewage from any one of its separate communities. For this purpose the whole populated area within the above limits is considered as forming one city with a common interest.

The growth of this metropolis was obtained partly from the United States census and partly from the school census of Cook County, which gave a record up to the summer of 1886. In order to forecast the probably ratio of the future increase it was desirable to compare this growth with that of other cities. By considering the ratio in increase elsewhere, and including the natural suburbs of each city, a fair and instructive basis of com-

parison was obtained; and by realizing the respective natural advantages for growth in each of the communities the probable ratio for Chicago was determined with a satisfactory degree of exactness.

The accompanying diagram shows the results of this comparison. It represents by curves the population of the largest cities in the country since 1790, not as usually quoted from the census, giving the inhabitants on certain arbitrary areas fixed by law, but as virtually making up the population of the respective municipalities, by including adjacent towns and natural suburbs, the only method which enables the true growth of the great cities to be recognized. For instance, the New York center naturally includes Brooklyn, Jersey City, Hoboken, Newark and other suburbs, and Chicago the entire territory from Hyde Park to Evanston.

The diagram indicates that the character of growth of the different cities permits them to be divided into two distinct classes. Philadelphia, Boston, St. Louis and Cincinnati show very much the same character of increase, and represent by comparison the more conservative communities. New York and Chicago, on the other hand, while showing a remarkable resemblance to each other, form quite a contrast to the rest of the cities, and might be called the more progressive communities. The diagram finally indicates the time when the Chicago curve, which was the lowest one prior to 1864, intersected in turn those of St. Louis, Cincinnati, Boston, and there is a high degree of probability of its intersecting the Philadelphia curve in or before 1891—*i. e.*, in four years from now—after which Chicago will be the second largest center of population in America.

As it is not practicable in so young a city as Chicago to forecast a definite line of growth, it is preferred to give the probable maximum and the probable minimum between which the true line will most likely be contained. The minimum line represents a growth resembling that of New York and the maximum line assumes the ratio of increase per decade to be consistent instead of gradually decreasing as in most other cities. The result indicates that the population of Chicago and suburbs will be 2,500,000 between the years 1905 and 1915, or about three times the present population in 18 to 28 years.

In providing public works for large communities it

must be borne in mind that it is economical to invest only such sums as will bring a return within a certain number of years, leaving expenditures for benefits that will be realized only at a later time to a later generation. This fact, together with the probable growth of Chicago, shows it to be economical and judicious at present to plan works sufficiently extensive to dispose of the sewage of not less than 2,500,000 inhabitants.

In addition to the population the area that will be occupied by it has to be determined. While this is a far more difficult task, owing to the many accidental causes influencing the distribution of the population, it is possible nevertheless to outline the area sufficiently close for the present purposes.

The future metropolis, with a population three times as great, will be distributed along the lake from South Chicago to Evanston, and will reach inland to the Blue Island Ridge on the south to the Des Plaines River in the center, and to the higher parts of Niles Township in the north. Outside of these general limits, a more or less dense population will extend for some distance along the lines of railroad.*

As inferred above, it is proper to consider at this time the wants of the population that will reside upon this entire territory.

DISCHARGE OF THE SEWAGE INTO LAKE MICHIGAN.

To discharge the sewage from cities into comparatively large bodies of water is not only the usual, but often the best method for its disposal. Dilution and dispersion thoroughly expose it to the action of the oxygen contained in both the water and the superincumbent air; it is thereby gradually oxidized. Where the body of water is a large river with a strong current, the best conditions for such purification are found. Where it is a lake in which the circulation is slight and irregular, the efficacy of the method is less and depends for its success on the character of the currents and the relative amount of sewage to be discharged into it.

The hydrographic surveys of the lake made during the past season were therefore partly for the purpose of

*Here occurs a diagram showing the "growth of several population centers in the United States," not here reproduced.

ascertaining, if possible, the laws governing the currents, so that we would know their effect in dispersing the sewage discharged into the lake. The trend of the shore currents was actually ascertained by daily recording the direction of spar buoys placed at the Chicago waterworks crib, at Michigan City and at St. Joseph. A large number of bottle floats were thrown into the lake at different points and different times for the same purpose. They were partly single surface floats and partly double, the lower one being placed at varying depths, according to the depth of the water. More than half of them have been picked up and returned, with place and date noted. The currents were also observed by means of large can buoys from an anchored tugboat at different points in the lake, extending from Hyde Park to Evanston, about six miles from the shore. Two general lake trips were undertaken, one to St. Joseph and Back to Grosse Point, and another one parallel with the shore around the head of the lake.

When the observations are completed and compiled in detail, some valuable information will be available for the question of water supply. Light will be thrown on the movement of the water under different winds and the sudden changes of temperature of the water at the crib and on the turbidness of the same.

The following results have a bearing on the question of sewage disposal: Where not affected by local conditions, the currents practically go with the winds in water of moderate depth and quickly respond to any change. In deep water also the surface currents run with the wind, but at the bottom and even at mid-depth the direction is usually different. The prevailing current along the shore of Cook County during the past summer has been observed to be toward the north, but it is possible that this result may be different during the winter months. In the open lake wave action seems to be effective in preventing the permanent deposits down to a depth of about 60 feet; inside of the breakwater sewage deposits are found on the bottom.

The general deduction from these results is clear that, as no constant current exists which would carry the sewage away in one direction, it should be discharged into the lake at one end of the future city, while the water supply should be obtained as far away from it as prac-

ticable towards the other end, a conclusion which is being acted upon in the other large lake cities. The proper place from which to bring the water would be opposite Grosse Point, and the sewage discharge should be east of Hyde Park. While it might be practicable to allow the sewage in its crude form to enter the lake under such conditions for many years, the necessity would arise later for clarifying it at least partially previous to its discharge. It could not be allowed to run into the river as at present, but the dry weather flow and a considerable amount of storm water would have to be intercepted and carried to the outfall through many miles of special conduits. This entire quantity would have to be raised by pumping in order to get sufficient head to empty into the lake, while the diluted sewage during storms, in excess of the capacity of the intercepting sewers, would be allowed to discharge directly into the river.

The water supply would have to be brought from Grosse Point in large conduits to the several pumping stations scattered over the city and its present suburbs. The circulation of the water in the Chicago River and branches would have to be maintained practically as it is at present, because the removal merely of the dry weather flow of sewage would not altogether prevent its pollution.

Disposal of Land.

We shall not at this time enter into a general discussion of the principles underlying land purification of sewage, or make historical references showing the success or ill success of the method as practiced elsewhere. We will simply state that with good management under ordinarily favorable conditions a disposal on land proves satisfactory, so far as the purification of the sewage is concerned, and that with proper conditions in the way of good markets and a favorable soil and climate sewage farms can be operated on a large scale after the sewage is delivered upon the same without financial loss.

In speaking of a sewage farm of the magnitude required for the metropolitan area of Chicago, it is not understood as being land devoted primarily to the raising of crops, using the sewage only when and where it would most promote the growth of vegetation. The primary

object would be the purification of the sewage on an area of land as small as could serve the purpose. Technically speaking, the sewage disposal would be by means of intermittent filtration rather than irrigation. To carry out such a scheme for Chicago involves the following:

(1) The acquirement of sufficient land suitable for the purpose.

(2) A comprehensive system of intercepting and collecting sewers carrying the sewage to the farm.

(3) Pumping works of a capacity to handle all the dry weather flow of sewage and a certain proportion of storm water.

(4) A thorough underdrainage, leveling and preparing of beds for the filtration areas.

(5) A system of underground conduits and surface carriers for distributing the sewage over the ground and a system of open ditches for removing the purified water to the nearest water courses.

(6) Buildings, roads, and a complete farming outfit.

(7) An organization for properly distributing the sewage, for carrying on the farming operations, for conducting the business of disposing of the crops in the best market.

In making estimates for the size of intercepting sewers, conduits, pumps and area of land required, we have used as a basis a population of 2,500,000 people, with an average dry weather sewage discharge of 150 gallons, or 20 cubic feet, per head daily, and made provision for storm water equivalent to one-fifth of an inch in 24 hours over all portions of the district now drained or likely to be drained by a combined system of sewers, allowing surplus water to escape in the rivers and lakes.

The dry weather flow of sewage would therefore be 50,000,000 cubic feet per day, and the maximum flow of storm water 65,000,000 cubic feet per day, making a total maximum discharge of 115,000,000 cubic feet.

From an examination of rainfall tables we conclude that the annual amount of storm water that would be carried off by such an intercepting system would range from 9 to 12 inches, an average of which in round numbers may be taken at 40,000 cubic feet per acre per annum over the area drained by a combined system of sewers. It is practicable, however, to exclude the storm water from the sewers over a large portion of the future city

by adopting the separate system of sewerage. The area north of the town of Jefferson and of the middle of Lake View may be treated to advantage in this way, and also a large portion of Hyde Park, Lake Calumet and other adjacent towns.

Assuming that the area which does not allow the storm water to be entirely excluded is 140 square miles, the average daily amount becomes 10,000,000 cubic feet, which gives, when added to the sewage, 60,000,000 cubic feet, or 24 cubic feet per head of population per day to be provided for on the farm.

As the amount of land required to purify sewage can only be determined by experience, and as this has been very limited in our own country, we are forced to rely mainly upon that of Europe. Without going into details at present, we will simply state that a fair consensus of this experience justifies us in the conclusion that from 10,000 to 15,000 acres of land would be required to dispose of the sewage from the entire metropolitan area.

The only available territory for sewage filtration in the neighborhood of Chicago consists of two sandy ridges in the Town of Thornton, extending across the state line into Indiana, and in a sandy ridge crossing the Town of Niles. The soil is quite favorable, but the character of the surface is such that the necessary preparation to make it suitable for filtration beds would be comparatively expensive. An enormous cost is, however, represented by the fact that the sewage would have to be collected by large intercepting sewers, lifted altogether some 90 feet, and carried about 20 miles before reaching the farms. We therefore consider such a project entirely impracticable.

The land treatment can only be seriously thought of in connection with the sewage disposal from the smaller areas mentioned above and comprising the extreme northern and southern parts of the future metropolis. The drainage of parts of Evanston, Lake View and Niles might be taken to the sandy ground in the latter town, and that of the Calumet region to the sandy ridges in Thornton, should this method be found most advantageous when compared with others.

The preliminary investigation made for this purpose consisted in an examination of the grounds in the projection of a farm, and in an estimate of the cost of pre-

paring the same and delivering the sewage to it by intercepting sewers and conduits.

DISCHARGE OF THE SEWAGE INTO THE DES PLAINES RIVER.

A third solution of the drainage problem is rendered practicable by the fact that the divide between Lake Michigan and the Mississippi Valley lies about 10 miles west of Chicago, with so slight an elevation that it is not a difficult matter to carry the sewage from the city westward into the Des Plaines River, and thence into the Mississippi River. The method of disposal, as previously explained, is in fact mainly the present one, most of the sewage now being carried across the divide by the Illinois and Michigan Canal.

There are two low depressions between the future metropolis and the Des Plaines River—the Mud Lake Valley, with the present canal, and the Sag Valley west of Lake Calumet. Neither is more than 10 feet above the lake, nor do they present any engineering difficulties for canal construction. It is therefore quite feasible to carry all the drainage from the territory ultimately to be occupied by the metropolis, extending from Lake Calumet to Evanston, into the Mississippi Valley through these depressions, avoiding thereby all possible lake pollution and permitting the supply of water to be drawn from any number of convenient points in front of the city.

The possibility of this solution was recognized as early as 1856 by Mr. E. S. Chesbrough, and the first step towards its adoption was taken, as already mentioned, by turning the sewage into the Illinois and Michigan Canal. Not until quite recently, however, has it become practicable to consider the construction of a special waterway for sewage removal, because when the population was smaller the expense of the undertaking was too great.

The sanitary requirements demand a flow of water large enough to dilute sewage sufficiently to make it inoffensive along the river at all times. Beyond this, any increase in the size of the channel to provide for the storm water which naturally enters it should be kept at a minimum. A glance at the map and an examination of the ground show the possibility of diverting the greater part of the storm water from the metropolitan district without serious difficulty. Both branches of the Calumet River can be diverted west of the Indiana state line into Wolf Lake, and thence into Lake Michigan. The Des

Plaines River can have its flood water diverted into the North Branch near the north line of the Town of Jefferson, and the combined waters can be led from Bowmanville directly into the lake. Salt Creek, a branch of the Des Plaines River, can readily be turned southwardly near Western Springs, through a water course known as Flag Creek, at one time evidently its old bed, discharging into the Des Plaines opposite Sag, and thus reducing the necessary storm water capacity in the new channel between Sag and Summit.

In order to determine the probable quantity of flood water which can thus be excluded, it was necessary to ascertain the maximum flood discharges from all the watersheds in question. This requirement called for a gauging of Des Plaines, North Branch and Calumet Rivers; a gauging of the rainfall, which is a measure of the stream flow; a survey of the watersheds and an examination of the river channels. It was also necessary to make a reconnoissance of all possible lines for diverting the Des Plaines, the North Branch, the Calumet River and Salt Creek, and a survey of those which were most important.

The results indicate that each one of these diversions is both practical and economical. By adopting the "separate system" of sewerage for the territory lying north of the proposed Bowmanville channel, the surface drainage from this territory can be safely turned into the lake.

A second branch of the investigation extends to the elements governing the proper size of the waterway from which a large proportion of the storm water has been excluded. The area still draining into it will consist largely of paved streets and roofs, allowing of no absorption and shedding the water rapidly. It requires a careful consideration to determine the maximum quantity of water that may enter the proposed channel, and for which an ample allowance must be made to prevent a back flow of the polluted water to the lake.

The proper degree of sewage pollution in the new channel demanded a careful investigation. When sewage is mingled with a sufficiently large quantity of water it not only becomes inoffensive, but readily finds the oxygen which gradually purifies it. When the surface is covered with ice a greater dilution is necessary for this purpose than at other times when there is a constant

replenishment of oxygen from the air. The proposed waterway should, of course, provide immunity from offense at all times.

The information upon which definitely to decide this question will be given in the final report, as the data have not yet been all collected, owing to the necessity of making actual tests of the oxidization of the canal water under the ice, which is being done for the use of the commission by Dr. J. H. Rauch, secretary of the State board of Health. The summer conditions are presented in his late report on the water supply and sewage disposal of Chicago. The result of these analyses will be compared with those of other streams that are also polluted with sewage in order to show the rate of oxidization with varying degrees of dilution and aeration.

For the purpose of estimating the cost of the water channel we have assumed 3,600 square feet for the cross section and a velocity of the water 3 feet per second, or 2 miles per hour. This gives a discharge of 600,000 cubic feet of water per minute, or 24,000 cubic feet for each 100,000 persons, which we believe equal to the maximum requirements of a population of 2,500,000 people.

A third branch of the inquiry covers the selection of routes for the proposed canals.

Between Chicago and Summit three lines are practicable—one following the west fork and Ogden ditch, and another extending from the southwestern end of the south fork in a westerly direction to the Ogden ditch, and thence to Summit, and a third being an enlargement of the present canal. We are of the opinion that eventually both the first and second of these lines should be adopted, but that the second one should be built first in order to secure circulation in the south fork. From Summit westward the bed of the river and the present canal were the only lines to be considered. The best location has not yet been finally determined.

For the drainage of the Calumet region a simple inspection shows that a canal should start from the river at the southern point of Blue Island, and extend almost directly westward to the Des Plaines Valley at Sag.

A fourth branch of the inquiry relates to the study of such data as have reference to securing a proper circulation for the waterways within the city.

To throw light upon this point the variations of the lake level have been recorded since last spring by means

of an automatic gauge indicating an almost continual fluctuation, averaging several inches, and recurring at periods of about 20 minutes. During a low pressure of the atmosphere the amplitude of these oscillations increases, and not unfrequently reaches several feet. The accompanying diagram shows the level of the lake on August 16, 1886, at a time when an area of low barometer passed over it. From 6:40 a. m. to 6:55 a. m.—that is, in 15 minutes—the water fell 2 feet 10 inches.

A rising level causes an inflow to the river and drives the water of the latter into the slips, where it deposits a portion of its suspended sewage matter and becomes foul. A falling level reverses the flow, and the slips empty their foul water into the river and lake. During heavy fluctuations of the latter, such as the one referred to above, it has been traced more than a mile in the direction of the crib.

As the proposed canal from Bowmanville to the lake will lower the water of the North Branch at this point to the lake level, provision must be made for its circulation. The size of the Fullerton avenue conduit is not sufficient to furnish the water required for a current in both directions, nor would such an arrangement be satisfactory or economical. It will be necessary to establish a flow towards the South Branch from the lake opposite Bowmanville in order to prevent a future lake pollution by the proposed channel. This can be accomplished by placing a lock in the North Branch at any point that may be found most desirable and raising the water at the same time about one foot. If such a lock is placed at Fullerton avenue the present pumping works, with slight modifications, can be utilized.

Finally, it must be mentioned that circulation can be secured in the proposed waterways of the Calumet region, into which the sewage is discharged, by a gravity flow from Lake Michigan into the Des Plaines Valley through Lake Calumet and the Sag. The detailed features of this project have not yet been wholly matured the estimates of cost being based on a channel having a capacity of 1,000 cubic feet per second.

Comparison of Projects.

In the foregoing we have outlined the main features of the only three feasible methods of disposing of the metropolitan sewage, and have given the results of the investigation reached to date. A general conclusion as to the preferable method may be given at present, and also an approximate estimate of cost. But we are not able as yet to give either conclusions or detailed statements of the probable expense regarding all parts of the proposed work, and must defer them until the final report.

In comparing the projects we will first mention their probable cost and then their relative advantages.

The discharge of the sewage into the lake from a population of 2,500,000 in the manner described above, including the extra expense, otherwise not necessary, of taking the water supply of Grosse Point, would cost at least $37,000,000, with an annual expense for interest and operation of at least $2,400,000. It would require an immediate investment of about $20,000,000.

To dispose of the entire metropolitan sewage by filtration on land would require an investment of about $58,000,000, with an annual expense of over $3,000,000 for interest, pumping, and maintenance, after deducting the profit from the sale of crops. It would be necessary to invest at once about $34,000,000. Land disposal for the sewage from the Calumet region alone, with a future population of 300,000, would require an investment of about $4,000,000 and an annual expense of at least $250,000.

Finally, the cost of the Des Plaines project is approximately estimated as follows:

1. A channel from the South Fork to Joliet of the capacity heretofore given will cost between $17,000,000 and $21,000,000.

2. A diversion of the flood waters of the Des Plaines the North Branch, and Salt Creek will cost between $2,500,000 and $2,800,000.

3. Pumping works and locks for the North Branch will cost about $150,000.

Omitted; printed in House Ex. Doc. No. 264, 51st Cong., 1st sess.

4. A separate system of sewers to collect the sewage now discharged directly into the lake and to carry it into the river will cost about $600,000.

5. A channel from Lake Calumet to Sag will cost between $2,500,000 and $3,000,000.

6. A diversion of the flood waters of the Calumet River will cost between $350,000 and $400,000.

The total cost of the Des Plaines drainage project would therefore be, for the main district, between $20,250,000 and $24,550,000; for the Calumet district, between $2,850,000 and $3,400,000. The annual cost, including interest, etc., is estimated at about $1,300,000 per annum.

The pollution of the lake can be decreased and the present condition of the Chicago River, and particularly of the South Fork, can be improved by the immediate construction of the following works, which, with the exception of the pumping works at the South Fork discharging into the Illinois and Michigan Canal, are all a part of the final plan.

1. Channels diverting the flood waters of the Des Plaines, North Branch, and Salt Creek, as described above.

2. A modification of the Fullerton avenue pumping station and the construction of locks for the purpose of getting circulation in the North Branch.

3. A separate system of sewers to collect the sewage now flowing into the lake from the south division and to discharge it into the South Fork.

4. A waterway extending from the western end of the South Fork to the Illinois and Michigan Canal, with a new pumping station to promote circulation.

5. By raising the banks of the canal and by removing deposits this capacity can be increased 40 per cent. at a small cost, and thus provide for a greater flow of water in the same.

The cost of the works comprised under these five items is estimated to be between $5,000,000 and $5,500,000. They could be finished in three years, and would greatly lessen the liability of polluting the water supply, while the sewage would be disposed of in the best practicable manner until the final completion of the Des Plaines project.

It therefore appears that this project is decidedly the least expensive one for the present as well as for the future.

Besides the economical advantages of the Des Plaines, scheme, its superiority is still further emphasized by advantages of another kind. The proposed canal will, from its necessary dimensions and its regular discharge, produce a magnificent waterway between Chicago and the Mississippi River, suitable for navigation of boats having as much as 2,000 tons burden. It will establish an available water power between Lockport and Marseilles fully twice as large as that of the Mississippi River at Minneapolis, which will be of great commercial value to the state. The Calumet region will be much enhanced in value by having a direct navigable channel to the Des Plaines River and by a lowering of the flood heights of Calumet Lake and River. Within the city the water of the Chicago River and its South Branch will get a much better circulation if it flows by gravity than if it has to be pumped, the necessity for which would remain even if the sewage should be discharged through intercepting sewers, either into the lake or upon land. Upon either of the latter conditions an occasional overflow from the sewers into the river during heavy rains would be more objectionable than a constant discharge of sewage into a more rapidly flowing stream. Flood waters entering the lake by way of the Chicago River would carry into it much filthy matter, either suspended or deposited, notwithstanding the existence of intercepting sewers, but the proposed diversion of such waters before reaching the populated districts will for all time obviate this undesirable occurrence. Lowering the level of the North Branch at Bowmanville by its diversion to the lake will be equivalent to raising the low prairie extending towards Evanston and Niles and greatly benefit parts of these towns.

The Water Supply.

In reaching the conclusion that the sewage of the city should be discharged into the Mississippi Valley the question of water supply is materially simplified, because the lake will then at all times furnish good water wherever intakes are desired for an extension of the works.

The preliminary inquiry made with a view to ascertain the main features of an increased supply, comprised first, a compilation of data concerning the existing works both in Chicago and its suburban towns, which were collected

mainly through the courtesy of the respective authorities; and, secondly, a study into the most economical method of distributing the water over the metropolitan area. The following is a brief description of the existing works:

The present intake for the public water supply of Chicago is located in Lake Michigan about two miles from shore and the water is conducted to the city in two circular brick tunnels 5 and 7 feet in diameter. They extend parallel to each other under the bed of the lake, and 50 feet apart, to the north pumping works, where they are connected and where the 5-foot tunnel terminates. The 7-foot tunnel is continued under the city for a distance of 20,500 feet, to supply the west works on Ashland avenue near 22d street.

The tunnels from the source to the shore are built at a depth of 80 feet below city datum, or low water in the lake, and the 7-foot tunnel is continued on the same level for a distance of about 11,500 feet, where, to avoid rock excavation, it is inclined upward until at the west pumping station, the top is but 21 feet below city datum. The economical capacity of the two tunnels is between 90,000,000 and 100,000,000 gallons per day, or less than the present average daily consumption of water. Their maximum capacity is reached when delivering about 150,000,000 gallons per day, which is now nearly equaled by the demand during the hours of greatest consumption, and at the present rate of increase it is estimated that during the summer of 1887 the maximum demand for water will be at the rate of 145,000,000 gallons per day; during 1888, 150,000,000 gallons per day; during 1899, 167,000,000 gallons per day; and in 1890, 180,000,000 gallons per day.

To provide against accident or obstruction from ice or other cause in the main tunnels, and to provide against an inadequate supply in the near future, which appeared inevitable, a new tunnel is in progress of construction. The intake is located 1,500 feet from shore, and connection is made with the other tunnels at the north pumping works.

The distribution of the water is effected by pumping it directly into the water mains at the north and west stations. At the north works the three tunnels are so arranged and constructed that any one of them can be emptied when desired for repairs or cleaning, and both the

pumping stations still be supplied with water from the other tunnels. The total pumping capacity of this station is at present 67,000,000 gallons per day, but it will be increased to 91,000,000 gallons per day as soon as the new pumps now in process of erection are in operation.

The connections between the pumps, standpipes, and the distribution mains at these works have become so complex by the successive additions to the plant that an unnecessary loss of head is the consequence. As this can be remedied to some extent without great expense, we recommend that it be done at the first favorable opportunity. The station being on the shore of the lake, is not centrally located with reference to any part of the city, which renders it necessary to use a greater length of main pipe, with a consequent loss of pressure, to reach the consumers than would otherwise be the case. The total pumping capacity of the west side station is 60,000,000 gallons per day, and the connections between the pumps, standpipes, and mains are simple and effective, and the loss of pressure from this cause is a minimum. The location is better adapted to secure economical and satisfactory results than that of the north works, and with reference to additional pumping stations, which will later be necessary in other parts of the city, these works are well situated.

The following table compiled from the annual reports for 1884 and 1885 gives a detailed comparison of the cost of pumping at two stations, anthracite coal being used at the north side and good bituminous coal at the west side:

COST OF PUMPING 1,000,000 GALLONS 1 FOOT HIGH.[a]

Nature of expenditures.	1884.		1885.	
	North Side.	West Side.	North Side.	West Side.
Salaries	$0.01488	$0.02022	$0.01560	$0.01667
Fuel	.05313	.02855	.04590	.02482
Lubricants ...	.00064	.00186	.00057	.00160
Miscellaneous.	.00323	.00417	.00133	.00401
Total	$0.07188	$0.05480	$0.06340	$0.04710

[a]Here appears a "diagram showing water pressure in the Chicago water pipes." Not here reproduced.

The hydraulic merits of the system are shown on the diagram of water pressures from a survey made in December, 1886. The pressures have all been reduced to a common height above city datum and to a uniform height of water at the works. That diagram shows a greater loss of head in the vicinity of the north side station than at the west side. This is accounted for by the complex arrangements heretofore mentioned, and also by the relatively small area of mains, being only 16¼ square feet at the north side and over 21 square feet at the west side. Nearly equal quantities of water are pumped at each of the stations during the middle of the day.

The following table shows the pumping capacity of all the suburban towns having a public water supply, and the pressure ordinarily maintained at the works. With the exception of South Evanston, all take water from Lake Michigan.

Locality	Individual pump capacity.		Total pumping capacity per day.	Ordinary head at pump, in feet.
	Pumps.	Capacity per day.		
		Gallons.		
Hyde Park	2	3,000,000	.....	.....
Do	1	12,000,000	18,000,000	103 to 150
Lake	2	4,000,000	.....	.....
Do	2	2,000,000	12,000,000	100 to 190
Lake View	1	5,000,000	.....	.....
Do	1	3,000,000	10,000,000	92
Do	1	2,000,000	.....	92
Village of Evanston	1	3,000,000	3,000,000	92
Total	11	.....	43,000,000	.....

At the artesian well supplying the village of South Evanston there is a head of about 53 feet.

The pressure at different parts of the pipe system is very irregular. In Hyde Park it varies from 165 feet at the pumps to 10 or 12 feet at Forty-third street. In the Town of Lake the average head at the town hall is reported about 10 feet, with 188 feet at the pumps. In Evanston, South Evanston, and Lake View the difference of head in various parts of the villages is not very great.

The following table gives a comparison of the consumption and cost of water in Chicago and the suburban towns:

Locality.	Year.	Average head at pumps.	Average daily pumpage.	Cost per 1,000,000 gals., delivered.	Cost of pumping 1,000,000 gals. 1 ft. high.
Chicago (North side)	1885	113	38,369,134	$ 7.17	$0.06034
Chicago (West side)	1885	105	53,280,880	4.95	.04071
Evanston (Village	1886	113	787,000	17.00	.15000
Lake View	1886	...	1,983,000	11.85	.....
Town of Lake	1886	163	7,292,023	8.80	.05400
Hyde Park	1886	...	3,410,000	8.92	.....

The second point of inquiry was a study into the most economical method of distributing the water over the metropolitan area. We will at present refer to it but very briefly, mentioning only such conclusions as pertain to the immediate demands and leaving a fuller discussion of the details of this important question to the final report.

The comparatively level area upon which the city is located, and the practicability of taking the water from the lake along the city front at any desired point, after the sewage has been diverted, permits the most economical distribution to be ascertained by mathematical investigation to a much greater degree of exactness than is usually possible.

It is found to be less expensive for the densely populated areas to have pumping stations about 2 or 3 miles apart, because the loss of head and cost of mains and pumping to obtain the least allowable pressure are thus reduced to a minimum. In planning new works this fact should be considered, and locations so selected that they will be advantageous for the future as well as for the present.

The localities which we believe to be most suitable for additional pumping stations are near 12th street, in the central part of the city; near the Union Stock Yards; near Humboldt Park, and near Fullerton and Racine avenues.

When it is considered that at the present time the pumps are delivering during the busy part of the day at the rate of 120,000,000 gallons in 24 hours, which is nearly the maximum capacity of all the machinery, and that even with this large consumption of water it is impossible in some parts of the city to obtain water in the second story

of the buildings, it becomes evident that an increased supply is imperatively required, and being a work of years to build new tunnels, inlets, buildings, and machinery, the necessity of deciding upon the location of the new works as soon as possible, is readily seen. The locality which is suffering most from the want of water is the business section and the south part of the city, the lowest pressure extending from 12th street to the city limits. It will become necessary in the future to have two stations in this territory, one between Harrison and 12th streets and the other to be somewhere east of the Union Stock Yards. We are strongly of the opinion that of the two stations it will be advisable and most advantageous to build the one north of 12th street first, for the following reasons:

1. It will require a shorter tunnel from the lake to the proposed station and less expenditure for main discharge pipes to connect with the present system than would be the case with the proposed southern station. This is equivalent to less cost and a saving of time in construction.

2. If the southern station is built first it will require mains of larger capacity leading toward the city than will be ultimately necessary when the central station is built.

3. The location recommended is near the center of the greatest consumption of water, and will be a gain not only in obtaining greater pressure in the business district, but in removing the cause for complaint on the south side by increasing the pressure so that the water will flow to the upper floors of the highest dwellings.

4. All other parts of the city will gain by the construction in this location, as the north and west works will be relieved of the enormous drain upon them to supply water for the business part of the city. They will be better able to give a good head on the north and west sides, where the population is increasing very rapidly, and which will very soon be in the same unsatisfactory condition as now obtains in the southern end of the city, unless relief is afforded in the manner indicated.

The other pumping stations will gradually become necessary as the population increases, and for a population of 2,500,000 there will be a need for a total combined capacity of 375,000,000 gallons to provide for a daily consumption of 150 gallons per head. With several in-

takes and tunnels the danger from stoppage of the water supply by ice or accident will be reduced to a minimum, as it is not probable that more than one of them would be so endangered at the same time.

We believe that a submerged intake will afford a more reliable and safer structure so far as injury from passing vessels and stoppage by ice are concerned than a structure projecting above the water.

With the sewage kept out of the lake there is no need of locating the intake farther than two miles from the shore where water can be obtained sufficiently free from suspended earthly matter, and where a depth of about 30 feet is generally found, which is the least depth desirable for a submerged inlet.

After presenting the results thus far gained, indicating the general solution of the Chicago drainage and water supply problem, it remains to point out certain facts which may be useful in discussing some of the legal measures required to carry out the proposed work. We desire to state that in order to reach the best results it is imperative to have all the main drainage works, such as intercepting sewers, waterways, and pumping stations, executed and maintained under a single management. It would be economical also to design and operate the main works for supplying water to the entire metropolitan area on a uniform plan and under one management, for the same reason that it is economical to keep the north and west side pumping works under one control, thus giving facilities as far as practicable for a supply proportioned to the demand to the entire metropolitan area, including the towns not bordering on the lake. We do not wish to imply, however, that such a general authority need necessarily extend further than to the construction and maintenance of the tunnels and conduits furnishing water to the respective pumping works.

Regarding the limits for metropolitan drainage, the investigation has shown, as already indicated, that topographical conditions clearly define two districts for the future metropolis. The main district extends from the line of 87th street on the south to the north line of Evanston and from the lake westward to the Des Plaines River. Its sewage is collected into one channel and discharged into the Des Plaines Valley at Summit. The Calumet district extends over the natural drainage area of Calu-

met Lake and River south of 87th street, and has its outfall channel running from Blue Island to Sag.

The final report will contain several maps, showing certain features of the metropolitan area, namely, the distribution of the population in 1886, the existing works and main distribution pipes for water supply, and the existing main sewage works and five-foot contour lines over nearly the entire area. It will also contain maps and profiles of the proposed waterways and storm-water-diversion channels mentioned in the present report, and a map showing the lines of the main collecting and intercepting sewers of the proposed drainage district, and also the lines of new tunnels and the general distribution of the water supply.

In carrying on the present investigation its various branches are placed in charge of the gollowing gentlemen, of whose ability and industry we desire to make special mention: Mr. L. E. Cooley, principal assistant, had special charge of the hydrographic work; Mr. Charles H. Swan, of the sewage disposal on land; Mr. Francis Murphy, of the topographical work; Mr. O. Guthrie, of the river pollution, land damages, etc., and Mr. T. T. Johnson, of the water supply, sewerage and miscellaneous work.

Respectfully submitted,
RUDOLPH HERING,
Chief Engineer.
BENEZETTE WILLIAMS,
SAMUEL G. ARTINGSALL,
Consulting Engineers."

I will ask you whether or not the statements in that report to which I have just directed your attention are the statements to which you referred in your direct examination as the ones which you made on this subject in the year 1887?

Mr. Williams: I object to the form of the question. I object to incorporating in the question the report referred to as not being proper cross-examination; and I object further on the ground that in the reports are statements referring to matters concerning which the witness has not been asked on his direct examination, and the entire question is improper as cross-examination.

A. They are.

Q. And the statements in that report which purports to be signed not only by yourself, but by Mr. Williams and Mr.

Artingstall represented at the time the report was made your own best judgment on the subjects with reference to which you have been testifying, did it not?

A. It did.

Q. That is to say the report is one which appears to be signed by three engineers, but so far as the report itself is concerned, it represents your judgment on all of the matters that are there set forth?

A. It does.

Q. Now, I will direct your attention to the report Appendix F, which appears on page 42 of this document to which I have last called your attention, the same being a report to the International Waterways Commission on the disposal of the sewage of Chicago and vicinity by Rudolph Hering and George W. Fuller under date of December 18, 1906, which is as follows:

"New York City, December 18, 1906.

To the International Waterways Commission:

Sirs: In response to your recent request we beg to report herewith upon several propositions connected with the question of extending the method of disposing of the sewage of Chicago and vicinity by means of dilution with Lake Michigan water. Your instructions may be briefly summarized as follows:

1. Examination into the sanitary situation at Chicago so far as it is affected by sewage disposal.

2. Latest conclusions of sanitary engineers as to the amount of dilution which is required to make sewage inoffensive.

3. Is the extension of the dilution method to the outlying territory the only way to preserve the lives and health of the people of Chicago?

4. For the Calumet area, are there not other methods of sewage disposal which may be applied at a cost not exceeding much, if at all, the cost of the method of dilution proposed, and which will be equally effective in preventing the pollution of the lake water?

5. Description of the various systems of sewage disposal which are available for the Calumet area, with a statement of their relative efficiencies.

6. Statement of the approximate relative costs of the last mentioned so far as they can be given without the preparation of detailed plans.

You further state clearly in your letter of instructions

that you do not desire an investigation into the effect of the present method upon the navigation interests of the Great Lakes, as that has already been officially considered by yourselves. Further, you state that you accept as a fixed fact the Chicago Drainage Canal as designed and built, with its attendant diversion of 10,000 cubic feet per second of lake water through the Chicago River and its branches.

In accordance with further instructions we have not given consideration to questions of a legal or legislative nature. We have viewed this problem solely as an engineering proposition without regard to inter-state questions and other features associated with the fact that a portion of the future metropolitan area of Chicago will obviously lie within the State of Indiana. It is further understood that under the existing circumstances we are to give you our opinion without entering into such details as would be required by additional surveys or other field work beyond a personal inspection of the areas.

Sewage Disposal at Chicago.

Drainage Canal.—Nearly all of the sewage from the population of Chicago now connected with sewers is diluted with Lake Michigan water, which, since January 17, 1900, has been allowed to flow through the new drainage canal and thus reach the valley of the Illinois River. This method of disposal is the outcome of various investigations, particularly of a commission on the drainage and water supply of Chicago in 1886-87. It was formally adopted in 1889 by State legislation, creating the 'Sanitary District of Chicago,' specifically providing that the volume of lake water for purposes of dilution shall be 3½ cubic feet per second for each 1,000 of population connected with the sewers, or 20,000 cubic feet per minute for each 100,000 population.

Early Methods.—In early days part of the sewage of Chicago flowed directly into the lake and part into the Chicago River and its branches. From the latter a portion of the water and sewage, beginning over thirty-five years ago, has been pumped at Bridgeport into the Illinois and Michigan Canal, as is true to some extent today. It is understood that the old canal is to be discontinued by legislative action as soon as equivalent transportation and

power facilities can be arranged for by means of the new canal.

Area of Sanitary District.—In 1903 an act of legislature was passed extending the area of the sanitary district from 185 to 358.1 square miles, and including the 'North shore addition' of 78.6 square miles, and the 'Calumet addition' of 94.5 square miles. The area of the City of Chicago is 190,638 square miles, leaving 167,462 square miles as the area of the present sanitary district outside of the city limits.

There are several features to be noted in connection with the method of sewage disposal of the City of Chicago as adopted in 1889. It had been found to be the cheapest method then available for disposing of the sewage so that it would not pollute the public water supply, which was then and is now diverted from Lake Michigan through a series of intake cribs located at various distances from shore.

Intercepting Sewers.—To prevent such pollution it was of course necessary first to divert all of the sewage into the Chicago River. A pure water commission was appointed by the Mayor in 1897 to consider the question of intercepting sewers for that purpose. It recommended among others a large intercepting sewer to collect the sewage from the area along the lake front between Seventy-third and Thirty-first streets, and about a year ago a 20-foot conduit was completed on Thirty-ninth street, through which the diluted sewage from this area now passes to the south fork of the south branch of the Chicago River. At present there is a gravity flow of lake water ordinarily of about 40,000 cubic feet per minute. Pumps are now in process of erection by which ultimately there will be pumped through this conduit about 120,000 cubic feet of lake water per minute, or 2,000 cubic feet per second.

On Twenty-second street there was formerly a main sewer draining the area bordering on the lake front between Thirty-first and Sixteenth streets, and discharging into the lake. In 1898 the flow in this sewer was reversed so that its contents now discharge into the river.

On Twelfth street in 1898 the flow in the main sewer was also reversed.

In the heart of the city, or business section, the sewers have always discharged into the river and not into the

lake. The same is true of a considerable area lying north of the Chicago River and along the lake shore. To facilitate this discharge a conduit was put in service in 1880 at Fullerton avenue, through which there has been pumped about 12,000 cubic feet of lake water per minute into the North Branch of the Chicago River.

At the present time there is no sewage entering the lake between Surf street (just north of Lincoln Park) on the north side and Seventy-third street on the south side of Chicago.

Plans are under way for the construction of the necessary works to collect the sewage along the lake front between Seventy-third and Eighty-seventh streets and to pump it into sewers west of Halsted street, which lead to the Chicago River. There is very little or no sewage from this area now reaching the lake, as the district is yet practically unsewered.

On the north side there is an area between Surf street and the northern city limits and between the lake shore and the ridge between the lake and the river, which now discharges sewage into the lake, but which will be diverted next summer. This sewage is to be collected by interceptors conducting it to Lawrence avenue, where will be located a pumping station and a conduit for pumping the sewage and about 35,000 cubic feet of lake water per minute into the North Branch of the Chicago River.

Farther north, at Wilmette, a conduit is proposed to be built with a pumping station near the Northern Railroad bridge in Evanston, where about 60,000 cubic feet of lake water per minute will be diverted into the North Branch of the Chicago River.

SUMMARY OF FLOW TO CANAL.—The projected flow of the lake water to the canal through the Chicago River and its branches to the Drainage Canal may therefore be divided and summarized as follows:

	Cubic feet per minute.	Cubic feet per second.
Main stream, Chicago River	373,000	6,217
Thirty-ninth street conduit	120,000	2,000
Fullerton Avenue conduit	12,000	200
Lawrence Avenue conduit	35,000	583
Wilmette conduit	60,000	1,000
Total	600,000	10,000

The volume for the main stream of the Chicago River as above stated is obtained by deducting the remaining quantities from the total.

The satisfactory disposal of the sewage of Chicago by means of the new drainage canal requires that, at and after heavy rainfalls, the storm water and sewage from the watershed of the Chicago River shall not flow into Lake Michigan, and therefore it is necessary to secure a practical reversal of the original flow in the Chicago River.

The drainage area of the Chicago River is about 270 square miles. Flood flows in the river have reached a maximum of about 10,000 cubic feet per second, or 600,000 cubic feet per minute, and this fact was also an important element in fixing the minimum size of the present drainage canal.

As to the efficiency of arrangements for the reversal of flow, our inquiries lead us to believe that this has been accomplished in a satisfactory way. Up to the present time, and owing to the insufficient waterway of some parts of the Chicago River, the volume of Lake Michigan water going through the river has not approached the volume above stated. But there have been times when a continuous flow of the Chicago River has been toward Lake Michigan for perhaps two or three hours. This time is necessary to properly regulate the water level at the controlling works near Lockport.

Population of Chicago Now Sewering Into the Drainage Canal.

We find that the present population of Chicago is, in round numbers, 2,000,000 people, of which between 100,000 and 200,000 reside south of Eighty-seventh street, tributary to the Calumet district, but within the city limits. Of the remaining population about 300,000 reside in the southern lake front district. This area is tributary to the Thirty-ninth street pumping station, which, since about January 1, 1906, has brought about the diversion of the sewage from the lake into the South Fork of the south branch of the Chicago River.

There is still an area in the northwestern part of the city north of Lincoln Park, spoken of as the northern

lake front district, which drains directly into the lake. Its population may be very roughly estimated at 70,000.

There is a considerable area south of Seventy-third street and west of Halsted street, and also a portion of the northwestern part of the city, which are of a semi-suburban character. Some portions have been provided with sewers and receive the overflow from cesspools.

So far as we are able to ascertain from local officials and without making a personal canvass as to details, it appears that there are now, in round numbers, about 1,500,000 people sewering into the drainage canal. In addition to the sewage there enters it a considerable quantity of trade wastes, notably about 2,000,000 gallons from the stock-yard district, and from quite a number of other industrial establishments, such as tanneries, wool-pulling establishments, etc., as stated by the sanitary inspector in the last report of the health department.

It is our understanding that the present sewage disposal project for Chicago is not intended to provide for the disposal of trade wastes now discharged into the sewers. While comparatively little has been done as yet to remove them from the sewers, we have been informed that it is proposed to take up this matter actively.

Influence of Sewage on Chicago Water Supply.

The City of Chicago receives its water supply from Lake Michigan through a series of tunnels of various lengths, ranging from about one to five miles from shore. Most of them extend from the shore about two miles. The total pumping capacity for this supply is stated to be 529,000,000 gallons in twenty-four hours. In 1905 the average daily pumpage was recorded as 399,000,000 gallons.

Since the removal of the sewage through the drainage canal was systematically begun in January, 1900, the appearance of the water of the Chicago River has shown marked improvement.

The effect of the drainage canal upon the hygienic quality of the public water supply may be studied in connection with the typhoid fever death rates at Chicago, which are recorded in the next table, together with corresponding death rates for a number of other American cities. It is not to be assumed

that typhoid fever is entirely due to the pollution of the public water supply at Chicago or elsewhere, as it is well known that there are other means of transmitting this disease. But its relation to the public water supply is so intimate that it gives, perhaps, the best general idea of the sanitary quality of the water, and therefore it frequently has been used as a rough means of such measurement.

There are other factors besides the drainage canal to be considered carefully in connection with the typhoid fever statistics at Chicago, and some of which should be mentioned here. Prior to 1900 there was a substantial improvement in the public water supply, partly due to the extension of some of the intake cribs and tunnels farther into the lake and partly to the reversal of the flow of a number of sewers from the lake into the river, such as those at Twelfth and Twenty-second streets, in 1898. These are important factors in explaining the absence in the late nineties of such excessive typhoid death rates as were noted at the beginning of that decade.

Since the opening of the drainage canal typhoid fever in Chicago has been rather unusually prevalent at times. This was especially true in 1902-3, when, it is understood, portions of the supply became contaminated after leaving the intake crib. These accidental pollutions have since been corrected.

The report of the city chemist of Chicago, as given in the last annual report of the department of health, shows that on an average in 1905 the city water supply was considered by him to be safe about 85 per cent of the time.

While there has been a marked improvement in recent years in the quality of the Chicago water supply, due to the progressive elimination of sewage from the lake, there is still room for more improvement. These improvements refer to the pollution along the lake front north of Lincoln Park, which is being corrected, and to the "Calumet area" south of Eighty-seventh street, which is now under consideration.

COMPARISON OF THE ANNUAL NUMBER OF RECORDED DEATHS FROM TYPHOID FEVER PER 100,000 POPULATION AT CHICAGO AND OTHER AMERICAN CITIES, 1890-1905.

Year.	Chicago.	Milwaukee	Detroit.	Cleveland.	Buffalo.	Toronto.	Boston.	New York.	Philadelphia.	Baltimore.	Washington.

LATEST CONCLUSIONS AS TO THE REQUIRED DEGREE OF DILUTION FOR THE DISPOSAL OF SEWAGE WITHOUT NUISANCE.

The disposal of sewage by dilution depends on the amount of oxygen in the diluting water being sufficient to prevent putrefaction of the organic matter in the sewage as the latter undergoes bacterial decomposition. If the oxygen is deficient bacterial decomposition produced what is called "putrefaction," with its various attendant bad odors, such as noted for years in Chicago at "Bubbly Creek." If there is a sufficient amount of oxygen dissolved in the water to combine with this organic matter, decomposition goes on without any foul odors and the organic matter is reduced to inert matter in an inoffensive way.

This question is one of balancing the amount of oxygen in

a given volume of water with the amount of decomposing organic matter in the sewage, which naturally must vary greatly.

There are many observations of more or less accuracy available to give figures for this relation. The Massachusetts State Board of Health made a special inquiry into this subject for all local rivers in 1902, with conclusions, stated on page 452 of their annual report for that year, as follows:

"The results of the investigations show that where the quantity of water available for the dilution of the sewage in a stream exceeds about six cubic feet per second per 1,000 persons discharging sewage, objectionable conditions are unlikely to result from the gross pollution of all the water of a stream in dry weather. Under favorable circumstances, such as in cases where the sewage is discharged at many outlets into a large body of water, objectionable conditions may not result where the dilution is somewhat less than six cubic feet per second per 1,000 persons; but objectionable conditions have resulted in all of the cases thus far examined where the flow has been less than 3.5 cubic feet per second per 1,000 persons discharging sewage into the stream."

These conclusions apply for the most part to comparatively small streams into which much manufacturing waste is discharged and upon which mill ponds are situated.

There are times when the flow of water in the drainage canal appears to have been insufficient to eliminate objectionable odors entirely. How far this may be explained by confusion on the part of observers of the putrefactive odors emanating from the Illinois and Michigan Canal with those of the new canal, and how far it may be due to temporary reductions in the rate of flow in the new canal and river to facilitate constructive work, and also to the effect of rainfalls and to old deposits in the South Fork, we are unable to say.

The new canal appears to serve at present about one-half the population for which it was designed, and through it flows a volume of lake water which is variable, but which averages not far from one-half of the ultimate quantity.

It is our judgment that for large canals with the trade wastes eliminated a dilution of 3 1-3 cubic feet per second for each 1,000 population connected with the sewers also receiving storm water is as low a figure as it is now possible to state. Local conditions, especially temperature, which affects bacterial activities and the coefficient of absorption of oxygen by water, and still other matters, bear upon this question, the detailed discussion of which is not now neces-

sary. We feel certain that a dilution of 2 1-2 cubic feet per second would cause offenses at times, and probably also a dilution of three cubic feet per second.

Future Population on an Area Tributary to the Chicago River and Drainage Canal with Reference to Sewage Disposal.

On the basis of the diversion of 10,000 cubic feet per second of Lake Michigan water, on the present assumption of 3 1-3 feet per second as being the volume to be provided for each 1,000 population connected with the sewers, and on the assumption of eliminating objectionable trade wastes, the present method of disposal may serve until the population on the drainage area of the Chicago River reaches 3,000,000 people.

On the further assumption that through the Chicago River and various conduits connected with its branches there will be a flow equal to 14,000 cubic feet per second, which is the capacity of the rock section of the drainage canal, the maximum population which might be taken care of in this way is about 4,200,000 people.

With a large portion of the 270 square miles draining into the Chicago River, but not yet built up, even on a suburban basis, it is evident that in future years there will be a much greater population than now exists.

We have considered the rate of growth in Chicago from various viewpoints, notably the density of its population, and have compared its growth with that of other metropolitan districts. There is, of course, no way of predicting accurately how rapid will be the growth of Chicago in future years; but it is a reasonable assumption that before many years it will become a city of some five or six million of population. It seems reasonable to infer that the population residing upon the area tributary to the Chicago River and its branches will ultimately exceed both the 3,000,000 and 4,200,000 estimates above mentioned. In other words, the present dilution method will certainly not alone for all time take care of the crude sewage of this area.

There are several available methods for the purification of sewage, depending upon the degree of purification desired, as will be noted beyond in connection with the Calumet area.

It is not probable that the sewage of the old part of Chicago will ever be purified by artificial means, as it would be proportionately much more difficult and expensive to deliver

the sewage to suitable sites for purification than to continue the present dilution method. It is different with the outlying districts tributary to the Chicago River. In the future, when these districts become built up so that the population exceeds the limits above stated, the installation of sewage purification works will necessarily follow.

The more essential feature of this proposed canal, as obtained from local officials, may be summarized as follows:

Location.—The canal would extend from a point on the Little Calumet River near Blue Island, through the Sag Valley, and enter the drainage canal near Sag Station.

Territory Tributary.—The total drainage area of the Calumet River is 825 square miles, of which 473 are in Indiana. Within the limits of the sanitary district of Chicago and south of Eighty-seventh street, the area is 94.5 square miles, with a population of about 100,000 in 1900. It is stated that the population has nearly doubled within the past six years, and it is expected to reach a million people or more within a fairly short period, as the conditions for a manufacturing district are very favorable.

Size.—The size of this canal, as proposed, is such as to give a flow of 4,000 cubic feet per second.

Reversal of Flow.—The natural flow of the Calumet River exceeds 12,500 cubic feet per second. It is proposed, if suitable legislation can be secured, to construct a dam below Thorn Creek, at the southern boundary of the sanitary district, and divert into Lake Michigan, through a channel to be built about 17½ miles east of the state line, the flow of this stream, with a drainage area of about 587 square miles. The size of the proposed Calumet Canal is too small to secure at all times a reversal of flow of the remaining portion of the area, which is about 240 square miles. It is proposed to put a controlling lock on the canal east of Blue Island to prevent flood waters from this low area entering the canal, at which times sewage entering the river on the lake side of the lock would go into the lake.

The proposed canal is insufficient to carry in the future all the storm flows of the Sag Valley itself. These would, at least, in part, require diversion through present or other channels.

Cost.—The estimated cost of this proposed canal is $12,000,000.

Population to be Served.—On the assumption already stated, this canal, by dilution, would dispose of the sewage

of about 1,200,000 people, not including objectionable trade wastes. This makes the cost of sewage disposal $10 per capita for the entire future population, or about $60 for the present population. The sewage would for the most part reach the canal by gravity through the Calumet River, so that the cost of maintenance would be comparatively small.

In passing, we may say that the Calumet area, both in Illinois and Indiana, is certain to develop rapidly, and its population will eventually far exceed the above figure.

Relation of Sewage Disposal for the Calumet Area to the Water Supply of Chicago.

For the reasons above stated in connection with the reversal flow, the sanitary effect upon Lake Michigan water at the Hyde Park intake and vicinity of this proposed Calumet Canal would not be nearly as effective as that of the main canal for the Chicago River territory and neighboring intakes. This fact is important in connection with the degree of sewage purification required by artificial purification works to give a sanitary effect equal to that of the proposed canal.

There seems to be no doubt that at times the sewage entering the Calumet River under present conditions from this district pollutes the lake water from the Hyde Park intake crib. It may pollute the water at other intakes, but our evidence is not conclusive. In the future, when the Calumet area is built up, it is possible that intake cribs may be built nearer to the mouth of the Calumet River than is the Hyde Park intake.

In view of the fact that the proposed Calumet Canal can not keep all sewage out of Lake Michigan at times of heavy rainfall, it is important to note that the water supply of this section of Chicago will eventually have to be purified by modern filtration works. This can be done at moderate cost, and it will be the cheapest and best solution of this problem to filter the water supply of this district and to purify the sewage to such a degree that the effluent will be fairly clear and nonputrescible, that is, free from disagreeable odors. With additional expense the sewage effluent (of the quality just stated) can be given a supplementary purification, making it practically free of bacteria by treating it with a germicide or by filtering it according to water purification practice.

Under existing conditions we are firmly of the opinion that

all the purification required of the sewage of the Calumet district is to make it fairly clear and non-putrescible.

Available Methods of Sewage Disposal Other than that of the Dilution Method Proposed for the Calumet Area.

The degree of purification of sewage by various forms of treatment differs naturally under different local conditions, but from general experience approximate results may be compared, substantially as follows:

	Percentage purification.		
Method.	Suspended matter.	Organic matter.	Bacteria.
Fine screens (30-mesh or finer)..	15	10	15
Sedimentation	65	30	65
Septic treatment	65	30	65
Chemical precipitation	85	50	85
Contact filters* 85-90		65-70	80-85
Sprinkling filters* 85-90		65-70	90-95
Intermittent sand filters*.....95-99		90-98	98-99

*The figures for the last three forms of treatment are on the assumption that the sewage is given some form of preparatory treatment before it is applied to the filters, and that with the sprinkling filters the effluent is allowed to settle.

It is to be stated that none of the first four treatments above tabulated will by itself give a non-putrescible effluent. Therefore they can be used here only in connection with some form of filtration.

For large works filters can be more economically operated if the sewage is first clarified in part, as stated in connection with the above summary. The most appropriate method for this preparatory or preliminary treatment is considered by most sanitary engineers in this country and abroad to consist of septic tanks, which is the expression applied to sedimentation basins in which the deposited sludge is allowed to accumulate to undergo bacterial action.

There are several forms of filters, the most widely known of which, in this country, is the intermittent sand filter sometimes mentioned as the so-called "land treatment" for sewage disposal. This method was considered in 1886-87 for the entire Chicago area and reported upon unfavorably on

account of its being more expensive than the adopted method of dilution.

LOCAL EXPERIENCES.—We find that a feeling appears to prevail among some persons at Chicago against land treatment of sewage, due perhaps to the unsuccessful operation of the sewage farm at Pullman, which is situated within this Calumet area.

We are familiar with the facts and experiences at Pullman, and are clearly of the opinion that they are not necessarily a criterion for the Calumet area. This opinion is based partly upon the small size of particles of the soil at the Pullman farm, and partly upon the fact that the farm was devoted principally to agricultural rather than sewage purification purposes.

SAND AREAS.—We have examined the tracts of lake sand which are found in Indiana and to a limited extent in the township of Thornton, Ill. The latter areas are too limited in extent and too shallow to be considered for present purposes. The only areas of suitable porous sand for land treatment of the Calumet sewage are in Indiana.

We have collected five samples of this sand for mechanical analysis, and have obtained the results as to size of sand grains. Representative results average substantially as follows:

	Millimeters.
Effective size	0.15
Uniformity coefficient	1.45

If we disregard the state boundary line, a large tract of sand of a suitable character is available for the disposal of the sewage of this district. The best area lies between the Little Calumet and the Grand Calumet rivers, and extends east of Hammond for many miles.

Within the past six or eight years great strides have been taken in the field of sewage purification in connection with works of wholly artificial construction. We refer particularly to filters of coarse, firm material, such as broken stone, slag or clinker, and usually spoken of as "coarse-grained filters," as distinguished from fine-grained sand filters.

Coarse-grained filters are of two types, spoken of as "contact filters" and "sprinkling filters," according to the method by which the sewage is applied to them. These filters produce an effluent which will not putrefy when they are operated at a rate far greater than that which is possible for sand filters.

We shall describe briefly each of these types of sewage-purification methods and state their approximate cost of construction on suitable sites for the Calumet area, based upon unit prices in accordance with experience elsewhere.

An outline is first required, however, of the intercepting sewers, pumping stations, and rising mains necessary to collect and deliver the sewage to the filter sites, of which there are several available.

Regardless of the particular kind of filter found most suitable for the Calumet area, there are a number of features common to all methods, and which may be stated as follows:

Separate Sewers.—With the adoption of sewage filters for this district we are clearly of the opinion that it would be advisable hereafter to build a separate system of sewers for domestic sewage only. Some, if not all, of the existing main sewers could be used for the removal of storm and surface water only, and new sewers parallel them for sewage removal; or, some of the existing sewers could be utilized for sewage removal, requiring new structures for storm-water removal. Trade wastes should be excluded from all sewers. We have obviously not included in the cost of purifying the sewage any expense for the main sewers or laterals to collect it and deliver it to the interceptors.

Volume of Sewage.—We have assumed that the sewage of this district will approximate 130 gallons per capita daily on an average. With a population of 1,200,000 the total volume of sewage would therefore be about 156,000,000 gallons daily. We have also allowed for ground-water seepage up to 1,000 gallons per square mile per day.

Interceptors.—For purposes of making approximate but liberal estimates of cost of purifying the sewage of this district, we have prepared sketches showing the intercepting sewers which will be required in order to collect the sewage of the district at four or more centrally located pumping stations. We have assumed that these intercepting sewers will be built of concrete, and when flowing full have a capacity of 250 gallons per twenty-four hours for each person resident upon the area tributary to the interceptor. When full, these interceptors have been assumed to have a velocity of 2.5 feet per second. We have also assumed, after excluding that portion of the Calumet district reached by extreme high water in the lake, that on an average the population contributing to the four or more pumping stations would be about 20 to 25

persons per acre. On this basis the length and size of the necessary intercepting sewers have been obtained.

PUMPING STATIONS.—For convenience we have located four main pumping stations near Riverdale, Harvey, South Hammond, and South Chicago. There will be required, when the district is built up to the extent herein considered, a total pumping capacity of about 340,000,000 gallons daily, including necessary reserve capacity at each station.

SEPTIC TANKS.—Regardless of the type of filter adopted, the sewage would be screened at the pumping stations, and then flow through septic tanks having a capacity of eight hours' flow on an average. These tanks would be about 12 to 15 feet deep, built of concrete, and arranged in compartments, so as to facilitate septic action on the deposited sludge, but without such action taking place in the flowing sewage itself. Owing to the severe winter climate in this vicinity, it is our opinion that it would be wise to cover these tanks.

Of the solid matters in suspension in the sewage about 65 per cent would deposit in the septic tanks, and of these deposited solid matters about one-half would be liquidified and gasified by bacterial decomposition.

The sludge which would be removed at intervals of once a year or so from the tanks, is estimated to contain about 85 per cent water and to amount to about 2 cubic yards per 1,000,000 gallons. Bacterial action converts this sludge to a practically inert mass which can be pumped in thin layers on to adjoining land and allowed to dry.

This is the form of preliminary treatment in use in some 40 places in this country, including Plainfield, N. J., Saratoga, N. Y., Mansfield, Ohio, Champaign, Ill., etc. It is the preliminary step in the works under construction at Columbus, Ohio, after elaborate tests of different methods were made for a period of nearly one year. It has also been adopted recently at Baltimore, Md., Reading, Pa., and Waterbury, Conn., and has been recently proposed for Paterson, N. J., in a somewhat modified form.

This form of preliminary treatment has been and is now extensively used in Europe with satisfactory results where the tanks are built and operated to meet local conditions as to volume and strength of sewage.

The odors from large open septic tanks are seldom noticeable a few hundred feet away. Under good management a septic effluent can be applied to sprinkling filters so that no objectionable odors should be carried one-quarter of a mile.

The cost of building and operating septic tanks would be substantially the same for all filter projects, and is considered under each as a common factor.

Intermittent Sand Filters.

This well-known method consists of applying the partially clarified sewage coming from the septic tanks to areas of porous sand, below the surface of which at depths of from three to five feet are underdrains of open-jointed pipe to convey the purified sewage to the nearest water course. The sewage is applied only at intervals of once a day or so to a depth of perhaps six inches. Between applications the sand layer is allowed to drain so that its pores may fill with air. This aeration of the pores of the sand allows bacterial processes to convert the organic matter to a large extent to harmless mineral matter. The effluent is practically free of noticeable suspended matter and objectionable organisms and can be discharged directly into the nearest water course.

This method is now in successful use in 40 to 50 places in this country where porous sand areas are available. It serves a total population of about 350,000 people. Well-known plants are to be found at Framingham, Brocton, Clinton, and Worcester, Mass.; Pawtucket and Woonsocket, R. I.; Meriden and New Britain, Conn.; Saratoga, N. Y., etc.

From time to time it is necessary to rake, harrow, or plow the surface of intermittent sand filters and to remove the scum which slowly accumulates there. At intervals it is necessary to scrape off several inches of the upper portion of the sand layer when it is found that they are so clogged that harrowing and plowing no longer prevents the surface from remaining covered with sewage.

With crude sewage it appears from Massachusetts evidence, especially from the tests conducted for a period of nineteen years at the Lawrence Experiment Station, that it would be necessary to provide one acre of intermittent sand filters for each 500 persons connected with the sewers. When the sewage is given a preliminary treatment in septic tanks and when the filters are operated under intelligent supervision the area may be reduced so as to provide one acre per 1,000 persons.

The most suitable natural site for sand filters for the Calumet area is to be found in the State of Indiana, between the Little Calumet and the Grand Calumet rivers, east of the City of Hammond.

It is possible to build artificial sand filters within the Calumet district, but the cost would be much greater than for any of the projects considered in this report.

Based upon our knowledge of these filters elsewhere, and without considering interstate complications, we estimate that the cost of installing and operating such a plant, with its various appurtenances, east of Hammond, and of a capacity of about 180,000,000 gallons daily to serve a population of 1,200,000 people, would be as follows:

ESTIMATED COST OF CONSTRUCTING SAND FILTER PLANT AND APPURTENANCES.

Intercepting sewers, pumping stations, and appurtenances, including a daily capacity of 340,000,000 gallons, and rising mains	$5,070,000
Septic tanks, 60,000,000 gallons capacity, covered, including sludge disposal facilities	950,000
Intermittent sand filters, 1,200 acres, with distributors, drains, office laboratory, etc	3,600,000
	$9,620,000
Contingencies and supervision, 15 per cent	1,443,000
Total	$11,063,000

ANNUAL COST OF OPERATION.

Pumping, fuel, labor and repairs	$300,000
Supervision, analytical and clerical assistants, etc	25,000
Care of septic tanks, including sludge disposal	36,000
Care of sand filters	480,000
Supplies and miscellanies	25,000
	$866,000

Capitalizing the operating expenses at 5 per cent per annum there is obtained $17,320,000, which, when added to the estimated construction cost, makes a total sum of $28,383,000 for the sand-filter project.

Contact Filters.

These filters consist of beds of broken stone, slag or cinders, placed in uncovered basins to a depth of from three to five feet. The size of material ranges from about one-fourth to one inch.

The filters are ordinarily operated upon the fill and draw plan, that is, the gate on the outlet pipe is closed until the voids of the bed are filled with sewage from the septic tanks. After filling, the filters are allowed to stand full for an hour or so, then the sewage is allowed slowly to drain out, and this cycle of operation is repeated once or twice a day.

When the filtering material is drained the voids fill with air, and it is during these periods of draining that bacterial processes accomplish the purification of the organic matter, which to a large degree is lodged upon the surfaces of the filtering material as the sewage is slowly withdrawn from the bed. The rates of filling and drawing the beds may be satisfactorily controlled by a number of automatic devices on the market and which are in successful use in a number of places.

Contact filters are an English adaptation of studies made some fifteen years ago upon the gravel filters by the Massachusetts State Board of Health at the Lawrence Experiment Station. These studies were begun about thirteen years ago at London. As an outcome of these and numerous other investigations, contact filters have been adopted and are in successful use for dozens of English cities, the largest of which is Manchester, with a population of about 600,000.

In this country contact filters have been installed for a dozen or more small cities and numerous institutions. Perhaps the best known plants are at Plainfield, N. J., Mansfield, Ohio, and Charlotte, N. C. They are especially applicable to projects where only a small amount of head is available and where pumping would be required for sprinkling filters.

For large projects, and where pumping is not a factor, recent experiences with sprinkling filters show that as a rule they are more economical. Notwithstanding this, contact filters have served and will serve a useful purpose in the field of sewage disposal in this country. Their convenience of operation makes them especially suitable for small installations.

Many contact-filter plants have their beds arranged in terraces so that the sewage may be passed successively through

two or three filters. There are a number of advantages of this arrangement, but it is not applicable to the Calumet district, owing to the level area of the available sites. One of the advantages of the double and triple contact filters is that they may be operated from below during winter weather and thus guard against reduction in the rate of filtration due to freezing.

The most available and suitable local sites are: A tract west of Harvey and between the Illinois Central and Rock Island railroads; a track west of Hammond and the local branch of the Fort Wayne Railroad, and a tract between lakes Calumet and Wolf.

As to the rate of filtration, we have assumed that contact filters should be five feet in depth and that they would satisfactorily purify the effluent from septic tanks at the rate of 600,000 gallons per acre per twenty-four hours. This means that one acre of contact filters should be provided for every 4,000 persons connected with the sewers.

The effluent from contact filters operated under these conditions would be ordinarily free from objectionable amounts of suspended matter, and the amount of organic matter would be so reduced that it would not putrefy upon standing. On an average about 15 to 20 per cent of the bacteria in the crude sewage would be present in the effluent. It would not be improper to discharge such an effluent as it came from the filters directly into the nearest water course.

The amount of attendance required for contact filters is not great, and is covered mainly by the necessary gatemen, analysts, and foremen. At intervals of all the material would have to be removed from the filters, washed, and replaced.

The approximate cost of building and operating a contact-filter plant with all needed appurtenances of a capacity of about 180,000,000 gallons daily to serve 1,200,000 people may be estimated as follows:

ESTIMATED COST OF CONSTRUCTING CONTACT-FILTER PLANT AND APPURTENANCES.

Intercepting sewers, pumping stations, and appurtenances, including a daily capacity of 340,000,000 gallons, and rising mains	$3,300,000
Septic tanks, 60,000,000 gallons' capacity, covered, including sludge, disposal facilities	950,000
Contact-filters, 500 acres, with all piping, appurtenances, office laboratory, etc.	6,000,000
	$10,250,000
Contingencies and supervision, 15 per cent	1,537,500
Total	$11,787,500

ANNUAL COST OF OPERATIONS.

Pumping, fuel, labor, and repairs	$200,000
Supervision, analytical, and clerical assistants	30,000
Care of septic tanks, including sludge disposal	36,000
Care of contact-filters	260,000
Supplies and miscellanies	25,000
Total	$551,000

Capitalizing the operating expenses at 5 per cent per annum there is obtained $11,020,000, which when added to the estimated construction cost makes a total sum of $22,807,500 for the contact-filter project.

SPRINKLING FILTERS.

Sprinkling filters differ from contact filters principally in the method of application of sewage, which in our northern climates is discharged upon them in the form of spray from a series of fixed sprinkling nozzles placed about 12 to 15 feet apart. The filters are usually deeper and of somewhat coarser material than contact filters.

These filters are also an English adaptation of the Lawrence investigations with gravel filters some fifteen years ago. The English studies began at Salford in 1892 and have resulted in the adoption of this form of filter for many of the principal cities of England, the largest of which is the metro-

politan district of Birmingham, with a population of over 900,000. Some of these filters have been in successful practical operation for more than eight years. On the Continent this method is being adopted for portions of the suburbs of Paris and Berlin.

In this country this method has been studied with care at Lawrence, Mass.; Columbus, Ohio; Boston, Mass., and Waterbury, Conn. Filters of this type are now under construction at Columbus, Ohio, and Reading, Pa. They have been recently adopted for Baltimore, Md.; West Chester, Washington, Pa., and Waterbury, Conn. They have been recommended for use also at Paterson, N. J.

The important element of aeration is secured in sprinkling filters partly by applying the liquid as a spray and partly through the use of coarse material with voids of a size so that there is a vertical circulation of air through the filtering material at all times.

Suspended mineral and organic matters and some of the dissolved organic matters are retained upon the surface of the filtering material as the liquid passes in thin films over the surface of the particles. Bacterial activities reduce the organic matter to a material degree, and from time to time the remaining inert material cracks and peels and passes through the filter bed to the bottom. In order to be able to remove this accumulated matter, it is necessary to provide false bottoms for these filters. Filters of this type have been in successful use for more than eight years, without cleaning, and it is believed that under favorable conditions cleaning is not required oftener than once in ten or fifteen years.

The amount of suspended matter in the effluent of sprinkling filters due to this unloading of stored material is sufficient to require passing the effluent through settling basins, holding about two hours' flow, before discharging into the nearest water course. The settled effluent, of satisfactory appearance and with its organic matter so reduced that it will not putrefy, usually contains less than 10 per cent of the bacteria in the crude sewage.

There is a considerable range in size of broken stone and in depth of material as adopted in various large plants now built or building. Avoiding extremes, it may be stated that the depths average about seven feet, and the size of material ranges from about one to 2½ inches, mean diameter. We have assumed these figures for sprinkling filters for the Calumet area, to be built of broken stone at the sites already men-

tioned for contact-filters, namely, west of Harvey, west of Hammond, and between Lakes Calumet and Wolf.

We have carefully considered the climatic conditions at Chicago, and compared them with temperatures where practical experience with sprinkling filters have been obtained. There is no trouble from the freezing of the sprinkler nozzles through which sewage is applied under a head of six or seven feet. During zero weather some frozen sewage accumulates on the surface of the filter and at such times it is necessary to have some reserve area. We have assumed that under these local conditions one acre of sprinkling filters should be provided for every 15,000 people connected with the sewers, making a rate ordinarily of about 2,250,000 gallons per acre per 24 hours. As was demonstrated at Columbus, such rates for several weeks at a time may be doubled and still obtain a satisfactory non-putrescible effluent. This rate, expressed in persons served per acre-foot of sprinkling filter material, is only about one-half of that provided for at Columbus, Ohio, and one-third of that in several plants in England.

The approximate cost of building and operating a sprinkling filter plant with all needed appurtenances, of a capacity of 180,000,000 gallons daily, to serve a population of 1,200,000, may be estimated as follows:

ESTIMATED COST OF CONSTRUCTING SPRINKLING FILTER PLANT AND APPURTENANCES.

Intercepting sewers, pumping stations and appurtenances, including a daily capacity of 340,000,000 gallons, and rising mains	$3,300,000
Septic tanks, 60,000,000 gallons' capacity, covered, including sludge disposal facilities	950,000
Sprinkling filters, 80 acres, with all appurtenances, office, laboratory, etc.	3,600,000
Settling basins, 15,000,000 gallons' capacity	200,000
	$8,050,000
Contingencies and supervision, 15 per cent.	1,207,500
Total	$9,257,500

ANNUAL COST OF OPERATION.

Pumping, fuel, labor, and repairs	$200,000
Supervision, analytical and clerical assistants	30,000
Care of septic and settling tanks, including sludge disposal	54,000
Care of sprinkling filters	110,000
Supplies and miscellanies	25,000
Total	$419,000

Capitalizing the operating expenses at 5 per cent per annum, there is obtained $8,380,000, which when added to the estimated construction cost makes a total sum of $17,637,500 for the sprinkling filter project.

CONCLUSION.

In recapitulating the substance of the foregoing inquiry and referring specifically to your instructions, summarized at the outset, we conclude as follows:

1. The examination into the sanitary situation at Chicago, so far as it is affected by sewage disposal, revealed that since removing the sewage through the drainage canal the appearance of the water of the Chicago River has shown marked improvement. As regards the hygienic quality of the public water supply there has also been an improvement, due to the progressive elimination of sewage from the lake, which elimination should be completed within a few years.

2. The latest conclusions of sanitary engineers as to the amount of dilution which is required to make sewage inoffensive, are that a dilution of 3 1-3 cubic feet per second for each 1,000 persons connected with the sewers, as provided for in the enactment of the Illinois legislature in 1889, is as low a figure as it is now possible to state. We believe that with the elimination of objectionable trade wastes and the occasional dredging of the river, this amount of dilution will be sufficient to prevent offensiveness.

3. The extension of the dilution method to the outlying territory is not the only way to preserve the lives and health of the people of Chicago. The application of this method with flows of 10,000 and 14,000 cubic feet per second, respectively, for the area tributary to the present drainage canal will serve population not exceeding 3,000,000 and 4,200,000 respectively. For greater populations, other methods of sewage disposal will be required.

4. For the Calumet area, as well as other districts, there are several methods for the disposal of sewage, as effective as the present method of dilution in preventing the pollution of the lake waters.

5. All of these methods involve intercepting sewers and pumping stations to collect and deliver the sewage at suitable sites. Septic tanks are used for partially clarifying the sewage, which may then be applied to any one of three methods of filters, viz., intermittent sand filters, contract filters, and sprinkling filters.

All of these filters, if well built and well managed, remove the suspended and organic matters so that the effluents are practically clear and are non-putrescible. The removal of bacteria by these three types of filters averages at least 98, 80 and 90 per cent respectively. Such effluents may be discharged directly into any of the water courses of the Calumet region.

6. The approximate total cost, liberally estimated, without the preparation of detailed plans, for a population of 1,200,000, are as follows:

A.—Intermittent Sand Filters.

Construction	$11,063,000
Annual cost of operation, $866,000, capitalized at 5 per cent	17,320,000
	$28,383,000

B.—Contact Filters.

Construction	$11,787,500
Annual cost of operation, $551,000, capitalized at 5 per cent	11,020,000
	$22,807,500

C.—Sprinkling Filters.

Construction	$9,257,500
Annual cost of operation, $419,000, capital at 5 per cent	8,380,000
	$17,637,500

The present population on the Calumet area of the sanitary district being less than 200,000 would naturally require but a portion of the cost of estimated works and of their operation to be expected at the outset.

Of the available methods of disposing of the sewage of the Calumet area, other than by dilution, the sprinkling filter method, being the cheapest, both in cost of construction and of operation, and accomplishing an adequate degree of purification, is clearly the most advantageous one.

Very respectfully,

RUDOLPH HERING,
GEORGE W. FULLER.'"

I will ask you whether or not the statements in that report are the statements on this subject to which you have referred in your direct examination as having been made by you in the year 1906?

Mr. Williams: I object to the form of the question. I object to incorporating in the question the report referred to, as not being proper cross-examination; and I object further on the ground that in the reports are statements referring to matters concerning which the witness has not been asked on his direct examination, and the entire question is improper as cross-examination.

Q. (Last question read.)

A. They are.

Mr. Wilkerson: Now that report appears to be signed both by yourself and by Mr. Fuller. Each one of the statements in that report on the subjects with reference to which you have been testifying today represent your own judgment on that subject, does it, your best judgment in 1906?

A. It does; each one does.

Q. Now, with reference to the disposal of the sewage from Chicago, I note that in this report of 1906 you refer to three methods, the intermittent sand filters, the contact filters and the sprinkling filters.

A. I do.

Q. And as a result of your analysis of the three different methods which are there discussed, you reached the conclusion that the sprinkling filter offers the most economical as well as the best method of handling the sewage?

A. I did.

Q. That is the substance of your conclusion?

A. It is excepting that I state other than by dilution.

Q. Other than by dilution of course. That is you were dealing there with methods which could be employed aside from the dilution method?

A. Yes, sir, but I also state that in my opinion the sprinkling filter is the best method other than the dilution method.

Q. Now, in determining the advisability of these different methods of handling the sewage of Chicago, did you in the studies which you made of this subject in connection with the preparation of the reports to which I have just directed your attention give any consideration to the question of the injury, if any, which would be inflicted upon the people who lived along the river below Chicago by diverting the sewage in that way?

A. I did.

Q. Or were you considering the question merely from the standpoint of the people of Chicago?

A. No, sir.

Q. You took that into consideration?

A. Surely.

Q. Of course it is a fact that there would be some injury inflicted on those people by the diversion of so much sewage through the Desplaines River, isn't it?

A. If the people would use the water as a drinking supply; not otherwise.

Q. That is to say it would destroy the possibility of their using the water for drinking purposes for a considerable distance below Chicago, would it not?

A. It would unless it were purified by filtration, as is done in other places. For instance, the City of Hamburg and the adjoining City of Altona, constituting together about one million inhabitants, discharge all their raw sewage into the river Elbe, and both cities take the water supply from this river and furnish it to the people after filtering it.

Q. That of course is possible. It would be possible for the people who live along the river below Chicago to get their water supply in that way, by filtering the water?

A. Yes.

Q. In determining whether or not Chicago is to be permitted to dispose of the sewage in that way, you would regard that as a fair element to be taken into consideration, would you not?

A. Yes, sir,

Q. That is to say, the injury which might be inflicted upon the people who live along the river and the difficulties they

would encounter in purifying the water, in case they wanted to use it for drinking purposes; I say that is a fair element to be taken into consideration?

A. I should hardly put it that way.

Q. Just how would you put it?

A. I would say anybody taking a water supply from a river, and I even extend that to the lakes where there is navigation and commerce, should have its supply filtered before use as a potable supply.

Q. That is to say that is your judgment, is it not, that in order that the people of Chicago should have the kind of water they ought to have, the water even now ought to be filtered?

A. I think the time will come when all cities on the lakes will filter their water supply.

Q. And in order that Chicago should be absolutely on the safe side, this filtration system should be installed now, even though the sewage is taken down the other way?

A. I should hardly think that it would be necessary at the present time.

Q. But it would be desirable?

A. It is always desirable to improve, if you have the money to pay for it.

Q. Isn't it a fact in considering as to whether or not it is necessary, there is always an element of chance as to what is in that water; that you never can tell with absolute certainty, but the only safe way is, as you say, to have the water filtered, the only absolutely safe way?

A. That is the general opinion now, apparently.

Q. Now, with respect to the extent of dilution which is regarded as reasonable, I think is the term we have been using here, the purpose of the dilution where the sewage is taken away through a canal such as is at Chicago, is to get rid of the local nuisance, as I understand it; the odor in the water and offensive matters of that kind?

A. It is, generally speaking.

Q. That is, you can have just as much sewage in the water as is possible to get into it without having the water so bad that it becomes offensive locally?

A. Well, I should want a margin of safety. I would not go so far as to just get to the place where it might make a nuisance.

Q. Allowing a reasonable margin of safety?

A. Yes. Our limit is governed by that degree of dilution where we feel sure that there is going to be no nuisance.

Q. That is the purpose of having such a large dilution?

A. Yes, sir.

Q. It is merely to get rid of the local nuisance?

A. It is also to oxidize the sewage, make it disappear.

Q. So as to take care of the people who live along the river further down?

A. So as to remove it, so as to purify it, oxidize it.

Q. Well, what is the necessity for that? I am assuming now that the people who live along the river further down do not use the water for drinking purposes unless it is filtered?

A. Well, we certainly want to have as good rivers, as good water in the rivers as we possibly can for navigation purposes and for the riparian dwellers, people living along the river. We do not wish to create an objectionable river.

Q. What I am trying to get at is just the process of reasoning by which the conclusion is reached that 10,000 cubic feet per second taken from Lake Michigan will give a reasonable dilution for the sewage from a population of three million people. I would like to get the process of reasoning?

A. The process of reasoning was this: because I had to go through it at the time, before I made this report; I collected information where I could find it in our own country and also in Europe, as to how many people could discharge their sewage into a river of known capacity, without making the river objectionable, without making it apparent that sewage was discharged into it. Now of course that information was not often obtainable, but sufficient evidence existed to find that when a certain amount of water, let us say it varied from three to seven cubic feet of water per second for every thousand persons, was discharged into this water you didn't notice it. Now, the lower figure is one that is found in larger streams. The higher figure is one that seems necessary in smaller streams and where conditions are rather unfavorable for the effect of oxidation and dispersion.

Now, with this information before us, it was concluded that for the case of Chicago four cubic feet per second a thousand persons was a proper figure. This was afterwards reduced to 3 1-3 cubic feet per thousand persons per second. Evidence obtained subsequent to making the report seemed to make it safe to allow, instead of two million and a half of people, three millions of people to discharge into the water for which we have designed the canal.

Q. Now, I think you said that during recent years there had been some improvements devised whereby this sewage can be treated so that you can diminish the dilution; I think you said by a third to a fourth, so that if these methods were used in Chicago and the sewage were treated in that way, those tanks constructed and the sewage screened—is that it?

A. No, the sewage settled.

Q. The sewage settled, the 10,000 cubic feet per second upon which the original estimate was made would take care of more than 4,000,000 people, wouldn't it, 4,200,000?

A. Yes, sir.

Q. It would take care of approximately 4,000,000, if the sewage were treated in that way?

A. Approximately; you can't tell exactly.

Q. Now, in connection with the construction of this system of sprinkling filters, you spoke about the treatment of the sewage by hypochlorite?

A. Hypochlorite of lime.

Q. Hypochlorite of lime? That being a process to be used in connection with the sprinkling system?

A. Only if you desire to destroy pathogenic bacteria.

Q. Well, what kind of bacteria are pathogenic bacteria?

A. Pathogenic bacteria are disease producing.

Q. Would you regard that treatment as essential, even where you have the sprinkling system?

A. That depends on conditions. I would say, for instance, that I would not regard it nearly as essential under ordinary conditions as such a treatment of the lake water, because what I should fear in the lake water would be the sewage from navigation.

For instance it is known that the discharge of a typhoid patient from a steamer in the lake will be drawn, might be drawn into a water supply intake, and possibly communicate this typhoid fever to those who consume this water in the city. That is entirely independent of the question of the disposal of the sewage of the city.

Q. Then is it your view that all the drinking water that is taken out of the lake should be subjected to that process?

A. To filtration, to guard more against lake pollution than against any pollution by sewage, if that is reasonably purified.

Q. Then of course with reference to the lake water, there is always the danger which comes in time of flood, when the

water is not carried away through the river or the canal but goes out into the lake, is there not?

A. I do not think that exists in Chicago, does it.

Q. Well, if it does there would be—

A. If it does, there would be all the more reason for treating the water supply with hypochlorite.

To go back again to your first question, it is of course better to treat effluent sewage from sprinkling filters with hypochlorite than not. There may be some cases where the cost is hardly justifiable, and that is the reason why I say you can't make a general answer to that question. I did recommend it, I did recommend this treatment for a city on the lake.

Q. Where this German method to which you have referred is used, is there any element of value in the sludge after it has been subjected to that treatment?

A. The value would be equivalent to garden soil, no greater.

Q. It is equivalent to so much fertile dirt?

A. Yes, although garden soil sometimes must receive a fertilizer.

Q. Certainly?

A. This sewage sludge would have to, because it has been pretty well rotted out, and that which is of fertilizing value is to a large extent gone.

Q. Just go ahead, Mr. Hering, and explain fully what your views are with reference to the value, if any, in this sludge, after it has been subjected to this German treatment about which you testified?

A. At the present time in the German cities it has a very small value. Some of the farmers take it away and pay a very small amount, but most of it is dumped as an embankment, perhaps 15 feet deep, so that it is clearly of no value in that instance.

It clearly has no manurial value, and it contains naturally the undecomposed remains of sewage matter; a lot of hair is in it, fibres, which does not make it as uniform as leaf mould. It also contains bits of wood. I should not consider it worth as much as the ordinary garden soil as it is bought.

Q. Did I understand you to say that you had made any definite estimate of the cost of constructing means for subjecting this Chicago sewage to the treatment whereby the degree of dilution could be diminished by one-third to a fourth?

A. I have not.

Q. Have you any idea on that subject?

A. I have not.

Q. Can you give us that within wide limits?

A. I have made no estimate whatever.

Q. Would it be very expensive or would it be comparatively inexpensive from an engineering standpoint?

A. No, it would not be extraordinarily expensive. The tanks would cost to erect about perhaps $1.50 per capita.

Q. So that for that expense it would be possible to provide means so that 10,000 cubic feet of water per second would take care of 4,000,000 people?

A. After adding the expense of operation, maintenance, and removal of the sludge, and so on.

Q. Which I understand is not very large?

A. I have made no estimate; it would take care of a population of about 4,000,00.

Q. Have you given any thought to this phase of this question: Assume that the people of Chicago are allowed to take 14,000 cubic feet a second out of the lake, and no more than that, and the population grows to a point where that amount taken out of the lake will not give the proper degree of dilution, as a matter of fact we are still up against this question of constructing a filtering system, are we not, ultimately?

A. I could not say, because, as we have observed in the last 25 years, we are progressing, and we may not then build works just as we would today.

There is only one certain thing, and that is that the oxygen of the air will be required to oxidize the sewage when treated on land, and the oxygen of the water will be used to oxidize sewage when it is discharged into water. Those are the two elements, I believe, that will still hold us for many hundreds of years, if not forever.

Q. Speaking from the standpoint of what we now know on the subject, if we had 5,000,00 people in Chicago today and could take only 14,000 cubic feet of water per second out of Lake Michigan, we would be face to face with this necessity for filters, wouldn't we, a filtering system? Here is what I mean: I am putting the question now on the hypothesis that the Sanitary District were today permitted to divert 14,000 cubic feet of water per second from Lake Michigan. Assume that that were the fact, and also assume that Chicago had more than 5,000,000 inhabitants today, whose sewage had to be taken care of by that 14,000 cubic feet of water per second. I say on the basis of what we now know on the sub-

ject, there would be the necessity of constructing a system of filters?

A. If Chicago had 5,000,000 population today, with the present knowledge we have, the outlying districts of Chicago would probably have to have some separate treatment for their sewage.

Q. Either that or if all the sewage were attempted to be handled in the same way, we would have to have a system of filters. I am trying to get pure drinking water for Chicago.

A. I do not understand that.

Q. I mean, the excess sewage would have to be filtered?

A. Yes, that is what I understood. The excess sewage would have to be filtered.

Q. The excess over 2,500,000 population, in the light of what we now know today.

A. In the light of what we now know today. That would be, as I think, the best method today. Regarding the filtering of the lake water, I believe that would be necessary on account of the lake pollution.

Q. That would come from such a large population?

A. Not from the city pollution; the lake pollution coming from the population on the ships in the lake, or the lake pollution.

Mr. Williams: Q. That is a different problem entirely.

A. Yes.

Mr. Wilkerson: Q. That is to say if we had 5,000,000 people in Chicago, the conditions of trade and commerce would be such that in all probability the water of the lake would be so polluted as the result of those commercial conditions, that the water should be filtered?

A. I would not like to answer it that way, because it could not be very highly polluted. I do not care to use even the word "polluted." Water has caused typhoid epidemics that was as clear as any drinking water that you have on your table. I mean that the danger of getting disease producing bacteria into your water supply from the traffic on the lake, and if you like, from shore population, will in the future make it desirable in this country, as it is already in Europe, to filter the water supplies taken from lakes.

The Swiss lakes are not polluted. Lake Vyrnwy is not polluted. They are beautiful lakes. They supply the adjoining cities of Geneva, Zurich and Liverpool with water. Liverpool does not adjoin the lake but it gets its water from the lake; and that is done simply to ensure the purity of these

waters because of the incidental, accidental pollution of disease producing bacteria.

Q. The best learning on the subject is all in favor of filtering the drinking water, isn't it?

A. That is the best thing that will ever be done today. I do not think in a thousand years anything more than that will be done.

Q. It is the most effective thing that can be done to get the best results?

A. Yes, sir. May I state something more?

Q. Certainly.

A. I was going to say in none of the cases that I have mentioned does any sewage whatever go into the lakes.

Mr. Wilkerson: I understand that.

Mr. Williams: They are separate problems, sewage disposal and water purification.

The Witness: Yes.

Mr. Wilkerson: Q. So far as Chicago is concerned, however, the problem of pure water and the problem of sewage disposal are not absolutely separate problems, are they, because if the water supply of Chicago were filtered, it would not make any difference whether the sewage emptied into the lake or not would it?

A. I do not hold that view. I should, in the case of lakes, I should hereafter as heretofore advocate either the purification of the sewage, treatment in some degree or a separation between the sewage out-fall and the water intake, that is sufficient to make a mixture practically impossible, a mixture of the sewage and the drinking water practically impossible.

Q. That is to say, taking the first method that you have spoken of, you would have the sewage treated before it comes into the water of the lake, and if that were done and the water were filtered, then you would have as a result, pure water?

A. Yes. I want to be sure that the sewage could not be detected at the water intake.

Q. Why?

A. And after that still treat the water. Because you cannot detect the pathogenic bacteria. They are diffused in the water. They may be in very clear water, and as a matter of public safety, I believe the practice of both sewage purification and water filtration should be provided for wherever expedient; not because I am in that business, but because I think so.

Q. In response to the last question, which Mr. Williams

put to you you said that even if you had enjoyed in 1887 the same light on this subject which you enjoy today in view of the advancement of the science, you would still adhere to the idea that the dilution method was the better method for Chicago. I think that was the substance of what you said?

A. That was the substance.

Q. It is true, however, is it not, that in view of the new light which we have on that subject as the result of the investigation of the last twenty-five years, it would be possible for a city like Chicago, situated as it is there on the lake, to handle this sewage problem without the construction of any such works for the dilution of the water as were constructed; I say it would be possible to do it?

A. It is possible.

Q. And that would be by treating the sewage and by the construction of a system of sprinkling filters, that would be your method?

A. That would be the method that I would advocate today.

Q. Would the cost of such a sprinkling filter plant for two and a half million people be substantially double what it would be for 1,200,000?

A. Generally speaking, yes, but local conditions might make it necessary to remove these treatment works to sections that are available for the purpose, and that might in one case—for one part of the city, might cost a good deal more than for another part of the city.

Q. But generally speaking, would the cost increase about in proportion to the extent of the population for which you wish to make provision?

A. Yes, when you get the large figures, that is true.

Q. Of course, for the smaller plants you have to add more?

A. Yes.

Q. It would be more than half when the plant was a small one, but where you deal with large figures, where you get up into the millions in population spread out over a large territory, the cost is approximately in proportion to the territory which you serve?

A. Provided the territory was equally available.

Q. Besides the cost of constructing the plant, I assume that there would be an additional cost growing out of the necessity for altering the system of sewers?

A. There would, if you propose to treat the sewage on land, and treat it sufficiently well so that it could be dis-

charged into the lake; it would require a new system of sewers for the entire City of Chicago.

Q. Did you ever make any study of the City of Chicago with a view to determining how much it would cost to install one of these sprinkling filter plants to take care of the entire sewage of Chicago?

A. Not for the entire sewage of Chicago.

Q. You made it on the basis of 1,200,000?

A. I did.

Q. I mean studying the system of sewers with a view to ascertaining how much reconstruction would be necessary?

A. No, sir, never made that.

Q. You have never made an analysis of that?

A. No, sir.

Q. But the plan is one which from the engineering standpoint is entirely feasible, I understand?

A. Well, I don't know.

Q. That is, you would not want to express an opinion without having made a study of the subject?

A. I would not because—oh, I understand with the separate system it is entirely feasible?

Q. Yes.

A. I should say it was with the separate system completely installed, it is feasible to have sewerage purification works, to receive the sewage and to purify it; but I never made a study of the cost.

Q. Now, with respect to the construction of this sprinkling filter system to take care of a population of 1,200,000 inhabitants, I notice you have a figure for a population of 300,000 and also a figure for a population of 1,200,000. Would the figures for cost for a population of say 300,000 or 600,000 run about in proportion as the cost you have given for 300,000, 1,200,000; are those large enough figures so that if you wanted to find how much it would cost to build a plant for a half million people, you could determine it with a fair degree of accuracy from your figures for 300,000 and the 1,200,000?

A. I think if you draw a curve—

Q. You are referring now to the diagram in the report to Mr. McCormick which has already been identified here?

A. Page 39.

Q. Page 39 of that report?

A. There is a curve which gives the cost of introducing sprinkling filters on the Calumet area.

Q. The sprinkling filter cost line crosses the Calumet Sag canal cost line at the population of 900,000, doesn't it?

A. Yes, sir.

Mr. Williams: I object to counsel's asking what the diagram shows. The diagram shows for itself. It is not necessary to ask the question and it is not proper in the record.

Mr. Wilkerson: Now, with reference to this estimate of cost, I think you said the figures which you had stated in your first reports would be subject to some increase, on account of the advisability of using the hypochlorite treatment. Am I correct in understanding that that was the principal element of increased cost that you had in mind?

A. You said my first reports.

Q. Or reports.

Mr. Williams: The report to Mr. McCormick.

Mr. Wilkerson: The report to Mr. McCormick.

The Witness: That is the last report.

Mr. Wilkerson: The last report. I stand corrected.

The Witness: I would today add the cost of hypochlorite treatment. Just how far I would go with that, I could not say without a study.

Q. You have made no figures?

A. No, sir.

Mr. Williams: And in addition to that you would add—what was it you just stated?

Mr. Wilkerson: I thought that was all.

Mr. Williams: No, he testified with reference to the—

The Witness: I would change the estimate by increasing it so far as the tanks are concerned for collecting the sludge. I would today make them more expensive because of their being double instead of single, for the purpose of getting non-odorous sludge.

Mr. Wilkerson: Q. What per cent. of increase would there be for these sixty million gallons capacity septic tanks?

A. I could not say without making the figures.

Q. As to the amount of increase for the cost of tanks, I understand you to say you have made no estimate on that?

A. No, excepting what I gave you, the cost being $1.50 per person.

Q. That would be, on a population of 300,000, about $450,000; that would be an increase of about $175,000 on the tanks.

Mr. Williams: That is on 300,000.

Mr. Wilkerson: Yes.

Q. On the basis of a population of 1,200,000, the revised figures would be $1,800,000 instead of $950,000 as given in the table?

A. Yes, sir.

Q. Now, as to increasing the capacity on account of climatic conditions, have you made any particular estimate as to that?

A. I have made no estimate of cost on that.

Q. Would you increase it by a percentage?

A. If the conclusion would be that the increase in the size of the beds would be 25 per cent., then that would pretty nearly indicate the increase in the cost, although I would not like to be held exactly to those figures.

Q. And these items of increase, you state, are not because the matters which they cover are regarded by you as absolutely essential, but because you think it would make the plant have a higher degree of efficiency?

A. Well I should say that it was the proper thing to do for a first class city.

Q. You would say it was a proper thing to do, but would you not say that the figures which you gave in the report in 1907 would provide a plant which while it might not be as good as it might be, would in all essential respects answer the requirements?

A. Well, at that time we thought it was a proper figure. As I stated before, I did not wish to load it with anything that might possibly be cut off or postponed because it was for the system that was to be ruled out; and I would rather be under than over in my estimate in this particular case.

Q. Referring again to this hypochlorite treatment, I understood you to say that the cost varied from $1.25 to $2.50 per million gallons; and I wanted to bring out if I could what were the elements that entered into that variation in price?

A. The reason for that variation in price is the character of the sewage. If the sewage is loaded with more organic matter, it requires a greater amount of hypochlorite. If the sewage is very clear and comparatively free from suspended matter, it requires less.

Now, I am not able to judge as to the character of the sewage that you have in the Calumet region, therefore I gave you those two figures, between which I am quite sure the amount would be.

Q. Now, assuming that the quantity of sewage which is diverted through the present drainage canal is increased to the point where there is more sewage than would be permitted by this reasonable dilution of which we have spoken, and eliminating the looks of the water, the appearance of the water and any effect it might have on navigation, what other in-

jury would result from that increase in the quantity of sewage?

A. An increase beyond this figure that I gave you as being the proper dilution?

Q. Yes, beyond the point where there would be 10,000 cubic feet of water per second for three million people?

A. Well, if you did not take out the suspended matter or sludge, then you would get a pretty good sludge deposit that would decompose, putrify, develop gases; and these gases would rise to the surface, coming out in little bubbles which you see in such cases. These would bring up little particles of light floating matter, and then you would get an offensive appearance.

Q. An offensive appearance, and any odor?

A. And very likely some odor.

Q. Any very considerable odor?

A. That would depend on the amount of decomposition that was going on, or rather I should say of this putrifaction that was going on.

Q. You would hardly say there would be very much odor unless the quantity of sewage was increased very considerable above the point which you have indicated?

A. Well, yes, sir, I am making this limit of 3⅓. I found that later on when the Massachusetts State Board of Health made similar investigations they rather tended to increase that amount, and whether that was just simply a sensitiveness of the nostrils or not, I don't know.

Q. What I am trying to do is to eliminate the aesthetic elements and get down to the elements of substantial injury.

A. That is very difficult to say, because one person will have a different judgment from another.

Now take the standard given by Massachusetts, it varies I think from 3 to 7½, a very great variation, and you can't fix that exactly by any reasoning resulting from odor. You might fix it by assuming a certain chemical analysis, we will say a certain amount of free ammonia, or a certain amount of albuminoid ammonia; but even then in my opinion, two engineers or two chemists might fix different limits. It is a matter of judgment to a large extent.

Q. Isn't it a fact that the results that would come from increasing the proportion, if I may use that term, of sewage in the water would not do substantial injury to health or property or navigation, but would be largely the injurious effect upon the appearance of the river and the odor, if any, which might come?

A. That is certainly a difficult question to answer because it is so personal. One person has a very different idea about that than another; and in dealing with this question, which has been up to me many a time, I have always thought that the only safe figure is one which goes well inside of all the opinions that are likely to be obtained; apply, as we engineers do, a factor of safety, to be sure to get inside.

Q. Be sure and have enough water?

A. Have enough water.

Q. And that is what you tried to do when you made this estimate?

A. Well, I thought I was doing that when I fixed 4 cubic feet per 1,000 people, when that report was published; but afterwards it was changed to 3½; I think that factor of safety was taken out, to some extent.

Q. Of course so far as making the water unfit for drinking purposes or use of that kind, it would not make much difference would it because there is enough going in there now to make it unfit for that?

A. I do not think the drinking water question would cut any figure in that, because that water should not be used for drinking at all of course, without very thorough filtration.

Q. But so far as navigation is concerned, you would have to get a great deal more in to really affect navigation, wouldn't you?

A. I would not think so, since we had this discussion over here in Brooklyn. The navigation interests are objecting to some sewage in the Gowanus canal.

Q. I am referring to the condition as it is now in the drainage canal; you would have to put a good deal more sewage into it, very many times as much as goes in now before you would have any effect on navigation?

A. Well, the only effect on navigation would be a blackening of the paint of the vessels, such as occurs over here in Brooklyn, and the odor.

Re-direct Examination by Mr. Williams.

Q. Do you know what is the amount of solid matter in ordinary sewage per capita per day?

A. I can't tell you by heart. I have got lots of data at home on that subject, and I am going to publish a paper, I did want to publish it two years ago, on that subject.

We assume in our calculations for sludge treatment works about 0.007 cubic feet per capita daily.

Q. And the weight of it is about 75 pounds per cubic foot, is that what it would weigh?

A. That is what I think it would weigh, about a half a pound per person.

Q. In your answers, Mr. Hering, to the questions put to you by Mr. Wilkerson, respecting the desirability of purifying the water supply of Chicago and other lake cities, were those answers made with reference to general conditions, irrespective of the disposal of sewage, or as a matter of protection from sewage?

A. They were made irrespective of the sewage discharge from the city.

Q. And the necessity for installing purification plants as a result of the discharge from cities of the sewage out of the city is a different problem from the general desirability of having purification plants as a matter of precaution from the natural conditions arising from lake traffic and shore sewage and washings and things of that sort?

A. Yes, sir.

Q. In your opinion, would it be safe to discharge the effluent of the sewage of a population of a million two hundred thousand people into Lake Michigan, after that sewage had been treated by the sprinkling filters such as were designed and reported on by you in your report to the International Waterways Commission in 1906?

A. I think it would be safe, although today in view of the comparatively slight cost, I would add the hypochlorite treatment.

Q. I am speaking now of the filter systems that were designed and reported upon by you and Mr. Fuller to the International Waterways Commission?

A. I understand.

Q. That is the same system you reported on to Mr. McCormick?

A. Yes, sir.

Q. That is assuming no purification of the water supply?

A. Yes, sir, assuming no purification of the water supply.

Q. What percentage of organic matter would you reasonably expect to find in the effluent after it had been treated by that process; that is by the sprinkling filter process, and before it had been subjected to the hypochlorite of lime process?

A. I would have to look that up.

Q. In your opinion what percentage of bacteria is destroy-

ed by the sprinkling process, without the treatment by the hypochlorite process?

A. The usual assumption is from 95 to 99 per cent.

Re-cross Examination by Mr. Wilkerson.

Q. With reference to the percentage of bacteria removed by the sprinkling filters, what further have you to say with reference to the desirability of removing all the bacteria, and with reference to the relation of the percentage removed by some other part of the plant?

A. I will say that if you have final settling basins and expect some of the suspended matter to leave the filters for the purpose of being further purified in the settling basin that a higher percentage of bacteria in the effluent would rather be desirable than otherwise, because they would assist in the final purification.

The tendency is, however, to accomplish as complete a purification as possible in these sprinkling filters, so that no subsequent bacterial oxidation will be required in the settling basins, if they are at all put in for the purpose of turning out at all times a clear effluent. The sprinkling filters sometimes discharge a slightly turbid effluent when it is unloading, as the term is.

At the present time, the exact details of construction or operation of sprinkling filters, which is best, is not yet known and is in the process of development; with all prospects, however, of improvements being developed within the next few years.

UNITED STATES OF AMERICA,
NORTHERN DISTRICT OF ILLINOIS,
EASTERN DIVISION. } ss.

IN THE

District Court of the United States

UNITED STATES OF AMERICA, *Complainant,* vs. THE SANITARY DISTRICT OF CHICAGO, *Defendant,*	C. C. No. 29,619.

Depositions taken pursuant to stipulation of counsel for the respective parties, statutory notice being duly waived, at the Hotel Netherlands, New York City, on March 18, 1913, and on subsequent dates.

Appearances:

Mr. Wilkerson, representing the Government.

Mr. Adcock and Mr. Austrian, representing the Sanitary District.

All objections to questions, answers and exhibits shall be considered as having been made except as to questions involving form, and secondary evidence.

GARDNER S. WILLIAMS, a witness called on behalf of the Sanitary District, was first duly sworn by the Commissioner, and testifies as follows:

Direct Examination by Mr. Adcock.

Q. Will you state your full name?
A. Gardner S. Williams.
Q. Where do you live?
A. Ann Arbor, Michigan.
Q. Your place of business?
A. Ann Arbor, Michigan.
Q. What is your business?
A. Civil engineer.
Q. Are you a member of any societies of civil engineers?
A. I am a member of the American Society of Civil Engineers, and a member of the American Institute of Consulting Engineers; member of the Detroit Engineering Society; American Water Works Association; New England Water Works Association, and some other less important societies.
Q. Where did you take your early training?
A. I was graduated as Bachelor of Science in Civil Engineering from the University of Michigan in 1889.
Q. Have you had any experience in the hydraulics and hydrography of the Great Lakes, and studies of these subjects?
A. I have been interested in and connected with the study of hydraulics and hydrography of the Great Lakes since I became the civil engineer of the Board of Water Commissioners of Detroit in 1893. In fact prior to that, I was considerably interested in the problems of navigation and hydraulics on the Great Lakes from the standpoint at that time of the student, not having any official connection with it in any way. But I was at that time familiar with the discussions of the effects upon lake levels of various changes that were under contemplation at that time.
A. After you graduated from college in 1889, what did you do?
A. After graduation, I was located at Owosso, Michigan, in charge of water works construction for the season. Then I was with the Russel Wheel and Foundry Company in Detroit as engineer until 1893, when I went with the Board of Water Commissioners of Detroit as civil engineer to the

Board. I remained there until the fall of 1898 when I went to Cornell University and became Professor of Experimental Hydraulics, and Engineer in charge of the Hydraulic Laboratory.

I remained there until 1904 when I came to the University of Michigan as Professor of Civil, Hydraulic and Sanitary Engineering, which position I held until October 1, 1911, when I resigned, and since that time I have been engaged entirely in consulting practice.

Q. What general experience have you had, Mr. Williams, as an engineer, and with what projects have you been connected, in a general way?

A. I started with the water works construction at Bismarck, Dakota; then at Greenville, Michigan, and Owosso, Michigan; then with the Detroit Board of Water Commissioners, in which latter position I began consulting work.

I was the consulting engineer to the Ithaca Water Works Company, or Water Works construction, construction of purification plants, etc. While located at Cornell I was consulting engineer to the Michigan-Lake Superior Power Company on hydraulic installations for their power plant at Sault St. Marie; also upon discharge measurements of the St. Marys River, which were undertaken by them in about 1899 or 1900.

I was consulting engineer to the Edison Sault Electric Company and the Chandler-Dunbar Water Power Company, and as such designed and supervised the construction of the power plant in the Rapids at Sault St. Marie.

I was consulting engineer for the Eastern Michigan Edison Company on water power developments on the Huron River. I designed and supervised the construction and the overhauling of several water power plants. I designed and constructed a water power plant on the St. Joseph River, Michigan, for the City of Sturgis. I was consulting engineer to the United States Corps of Engineers on the substructure of the power house in connection with the lock and dam of the Mississippi River improvement between Minneapolis and St. Paul.

I was consulting engineer to the Canadian Light & Power Company in connection with power development and incidental improvements to navigation on the Couteau and Cedar Rapids of the St. Lawrence River near Montreal.

I was employed to advise the Central Colorado Power Company on the construction of certain dams and their effect upon the channels of some of the rivers in the vicinity of

Colorado Springs, particularly as to effects of floods. I have had meanwhile engagements in numerous other places, but I think those are the principal ones.

Q. Have you held any official position in societies of civil engineers?

A. I was a director of the American Society of Civil Engineers for one term, for a term of three years, which I think expired in 1910, I will not be certain.

I have been, for five years I believe, the chairman of the Board of Managers of the Association of Engineering Societies, which is composed of societies in Boston, St. Louis, Detroit, San Francisco, Milwaukee, New Orleans, and several other cities; the purpose being to provide for the publication of the papers and discussions that are presented before the Society.

Q. Are you connected with any publication relating to civil engineering?

A. Well, the Journal of the Association of Engineering Societies was published by the Board of Managers, of which I am the Chairman.

Q. Outside of your business connections have you made any special studies or presented any papers in connction with the hydraulics, hydraulic engineering and sanitary conditions, etc.?

A. I presented a paper before a sanitary convention in Detroit, in 1897, I think, upon the transmission of typhoid fever from Port Huron to Detroit through the channels of the St. Clair River and through Lake St. Clair, which involved of course a considerable study of the hydraulics of that section of the connecting waters of the Great Lakes.

I presented a paper to the American Society of Civil Engineers, which was published in 1902, I believe, upon experimental investigations upon the flow of water in pipes. And I have contributed to numerous discussions at one time and another on hydraulic and sanitary subjects. Those are the two principal ones.

Q. In connection with your engagements at Cornell University and the University of Michigan in the capacities which you have mentioned, what was the scope of the work there, and what studies did that cover?

A. The engagement at Cornell placed me in charge of the first, in fact the only large experimental hydraulic laboratory that has ever been constructed; in fact the largest that there has been in the world. The scope of investigations that were

carried on there, during my connection with it, involved first some investigations upon the flow of water in pipes, but more particularly investigations of the methods of measuring water in open streams, open channels.

Experiments were made upon the measurement of water over weirs by means of floats, and by means of current meters. And this work was carried on during the entire period of my residence there, which was substantially six years.

Q. When you speak of measurement of water by means of weirs and floats and current meters, will you explain just what those terms mean?

A. The measurement of water may be accomplished in a variety of ways. The most accurate method of course is to measure it by the weight that is delivered or involved. That of course is limited to comparatively small quantities of water.

The next method in accuracy is the measurement by volume, which may be done in considerable quantities in reservoirs and large basins, where the area of the surface is known and the rise of the water can be measured.

The next method in accuracy as ordinarily accepted, and as I believe it to rank, is the measurement over a weir. A weir is another term for a dam, but in this country it is ordinarily applied to a dam which is used for the measurement of water.

Extensive and elaborate studies have been made to determine the quantity of water which will pass over a weir or partition in a channel of known height and form for different heights of water above the crest or top of the dam or partition.

The most extensive series of experiments upon the flow of weirs on record are those made by the French engineer Henri Bazin at Dijon in France, from about 1886 to about 1889. In these investigations, the quantity of water that was measured over the weir, or that was passed over the weir was measured volumetrically in a basin which was composed of a part of a canal.

In America the first extensive investigations and perhaps the best known ones were made by Mr. James B. Francis at Lowell, about 1850. The volume of water handled by Mr. Francis was very much greater than had ever been attempted by anybody else, and was greater than was handled by Bazin.

The experiments which have the largest scope in the measurement of water over weirs of any that have ever been made

were made by Messrs. Fteley, Mr. Alphonse Fteley, who is now deceased, and Mr. Frederick P. Stearns of Boston, which were made in connection with the Boston Water Supply for the purpose of determining the quantity of water that was supplied from the Sudbury aqueduct which furnished the water to the City of Boston. The quantity of water measured in that case far exceeds anything that has been volumetrically measured anywhere in the world to date.

The investigations at Cornell did not involve volumetric measurements except in the instance of small quantities, but were based upon the comparison of two measuring devices; that is two weirs so situated that the water which passed over one would be passed over the other, and so that the conditions at the two weirs were markedly different, one of them being very large, that is nearly twice as high as the other, so that the water approached it with very much less velocity than it approached the other, and by comparing the discharges over these two, according to formulae which were derived from a study of the experiments of Bazin, Francis and Fteley and Stearns. These measurements of water over weirs were also compared simultaneously with measurements by means of rod floats and current meters.

The rod float is simply a weighted rod, which is so weighted and balanced that it will float with its top just above the water, and stand in a vertical position.

Q. Where is the bottom of it?

A. And the bottom of the float is made to pass near to the bottom of the channel.

In the experiments at Cornell, we had a perfectly smooth channel with vertical sides and we experimented with floats of different depths, ranging from a depth of 1/10 of the depth of the water down to about 98 per cent. of the depth, and compared the discharge so obtained with the discharge as indicated simultaneously by the weirs at the upper and lower ends of the channel. At the same time or at other times, measurements were made in the ordinary way with current meters which were located at various points along the canal between the two weirs, and in that way a comparison of the relative accuracy of the several methods was obtained.

Q. Will you describe the current meter as it is ordinarily used, as the term is used?

A. The current meter consists essentially of a revolving piece of apparatus, which is caused to revolve by the motion of the current when the meter itself is held still in it, or when

it is moved by an external force through the water. It also is furnished with a tail or vane which so directs it that if left free to assume its normal position it will point directly against the current. It is usually pivoted both in the horizontal plane and in the vertical plane, so that it is free to revolve in both directions, and assume the position in which the current is moving.

The revolutions of the wheel are caused to make and break an electric circuit, which are repeated in a sounding device that is held by the observer, ordinarily a small telephone which is simply fastened to its head, and at each revolution of the wheel there is a click so that he is able to count the revolutions of the wheel and at the same time with a watch thereby determine the number of revolutions that take place in any unit of time that is desired.

In transferring the revolutions to velocity of water, it is necessary to have the meter rated; that is to know how many revolutions per minute represent, say, a foot of velocity. That is ordinarily done by dragging the meter at known rates through still water, and recording the revolutions for the distance passed through in a given time, it being assumed that the velocity of the meter in still water has the same effect in creating rotation that the velocity of water past the still meter would have in creating rotation. That process of dragging the meter in still water and determining the revolutions which correspond to a velocity of translation through the water is called rating.

The meter as operated in small channels where it can be done, is ordinarily held upon a rigid staff, when both its direction and position can be very accurately determined. In working in deep channels, it is necessary to suspend the meter on a cable, in which case its direction cannot be determined with the ordinary meter and its position is more or less influenced by the necessary curvature of the lines, due to the effects of the current. To overcome the former objection, a current meter has been devised for that, which is known as the direction current meter, in which there is a magnetic needle that transmits its position electrically to what is known as a repeater at the surface, which indicates on the surface the position in horizontal direction which the current meter occupies, so that it is possible with that device to tell so far as the horizontal plane is concerned in what direction the meter is pointing; but with an ordinary meter it is not pos-

sible to determine that, unless the meter is within the range of vision through the water.

Q. When you speak of ordinary meter, what make of meters do you refer to?

A. Well, when I say "ordinary meter" I refer to all except those equipped with the direction meter device, which is only used in connection with the so-called Ritchie-Haskell direction current meter.

Q. What period of years did your investigations and work at Cornell cover?

A. About 1899, from early in 1899 or the fall of 1898 until 1904.

Q. What was the scope of your work at the University of Michigan?

A. At the University of Michigan, my work so far as that connected with the University was concerned, was mainly in the teaching of the subjects indicated by the title of my chair.

At that time I was engaged upon numerous investigations involving the measurement of water, the flow of water; made several investigations of the quantity of water flowing over various structures as dams, under particular conditions; that is the effect of various forms of crests and so on upon the low discharge of such structures, with a view of being able to determine more accurately the quantity of water that was flowing in rivers where such structures were in use, in connection with measurements of run-off of streams.

Q. During the time that you were at Cornell, and also at Michigan, were you engaged in any way in connection with your business as consulting engineer as you are carrying it on now?

A. Yes, all the time I was at Cornell, and even before that, and all the time I was at Michigan I was engaged as consulting engineer, maintaining a regular office and devoting probably from one-third to one-half of my time to my outside practice.

Q. Did the construction of the plants and your work in connection with that have anything to do with navigable waters?

A. The construction work at the Sault St. Marie was in what was assumed to be navigable water in that the War Department of the United States exercised control over the structures which were put there, and such structures could only be erected upon a permit from the Secretary of War.

The constructions with which I was connected at Detroit for the Board of Water Commissioners, which involved matters of intakes in the Detroit River, and for which I made extensive surveys both with regard to the hydrography and character of the bottom and so on of portions of the Detroit River and also Lake St. Clair; and as to the temperatures of the water at different places in the river; and also as to the currents which incidentally involved a considerable amount of current meter work, were all carried on in navigable waters, and subject to the interruptions of navigation. The work of gauging the St. Mary's River which was attempted by the Michigan-Lake Superior Power Company, under my direction, was also carried on in the navigable water of the river above the locks, at a point where vessels were passing, several every hour.

Q. What year was that?

A. Those measurements were made during the summer of 1900, I believe.

Q. Did you make any further measurements on the flow of the St. Mary's River subsequently to that time, or have you made any special studies in that regard?

A. I made no measurements subsequent to that time, but I made a very careful study of the records of flow and the conditions of flow in connection with the development of the water power in the Rapids for the Edison Sault Electric Company; and also in connection with the problems which were introduced in a suit between the United States Government and the Chandler-Dunbar Water Power Company and the Edison Sault Electric Company and others, for the purpose of condemning the property of the aforesaid companies. The general problem of the hydraulics of that part of the river was I think quite carefully considered.

Q. Have you made any study of measurements of the flow of the St. Clair River; and if so, what time did they cover?

A. I have made a very careful study of the flow of the St. Clair River. You mean a study of the measurements.

Q. Study and measurements both?

A. The measurements on the St. Clair River, the early measurements, date back to the early sixties, 1864, I believe, when discharge measurements were made under the old Lake Survey organization, at which time the current meter as it is now known was really developed, the first use of the telegraphic current meter, so-called, that is when the electric

device was made, at that time, in discharge measurement of either the St. Clair or the St. Mary's River or both, as both were gauged about that time.

The next work that was done on the St. Clair River so far as is known to me—and I have searched the records with some diligence—was in 1899 when the present Lake Survey organization took up the problem of measuring the discharge; and those measurements which were continued through 1902 and latterly taken up again in 1908 and carried on through 1910 have in the main been incorporated in the data already presented in this case. My study of those measurements began about with the inception of this case, although I had a general knowledge of them prior to that time; and had discussed them with various engineers of my acquaintance who were interested in them.

Q. Take the Detroit River, I will ask you the same question.

A. The gaugings of the Detroit River were made in 1901-2 at a section in the vicinity of Fort Wayne below the City of Detroit, and the results of these gaugings were published in the report to the Chief of Engineers for 1903, I believe. The work which I did myself on the Detroit River involved the gauging of the American channel through the ice in the winter of 1896 I think, or possibly January, 1897. There were also several gaugings of the Detroit River in the vicinity of Amherstburg made during 1908, 1909. I am in doubt about 1908. I think they were made in 1909 and more in 1912, in which measurements were made of the several channels, during the construction of the so-called Livingstone Channel, and after the opening of the channel. Those gaugings were made by the United States Government through the River Improvement office at Detroit; the work being in charge of Mr. Charles Y. Dixon, Assistant Engineer in charge of the work in the Lower Detroit River.

Q. What have you had to do with the measurements or consideration of the flow of the St. Lawrence River, and during what period did that cover?

A. The St. Lawrence River was gauged in 1900 and 1901, and there have been gaugings within the past two years I believe.

The data of the 1900-1901 measurements have been utilized in the preparation of exhibits for this case. My individual study of those measurements began at the time that this case was opened. Succeeding that I had occasion to be associated

with the gauging of the St. Lawrence River at a point considerably lower down, being at the bridge across the river just above the Couteau Rapids. This work was done for the Canadian Light & Power Company of Montreal, in connection with the proposed power development and navigation improvements which they were contemplating through the Couteau and Cedar Rapids; and the work was in charge directly of Mr. Murray Blanchard, who was formerly an assistant engineer or junior engineer in the United States Lake Survey service, and was an assistant upon the work on the St. Clair River during the first three years and in charge of it during 1902, and then was in immediate charge of the measurements on the Detroit River in 1901 and 1902.

These gaugings were also supplemented by gaugings of individual channels in the Couteau Rapids, carried out by the same organization.

Q. Have you made any study or investigations concerning the Lake levels and the relation of the levels of the different lakes to each other, with reference to run-off and rainfall, etc., and if you have state what investigations you have made, and what studies you have made?

A. The subject of the discharge of the Great Lakes, in its various phases, has been one that has attracted my attention for a good many years, and I have made, I think, a very careful study of the elevations of the lake, the discharge of the lakes as indicated by such measurements as have been made, the effects of rainfall so far as those effects can be determined, or so far as I have been able to determine them from such records as are available in the files of the United States Weather Bureau, Smithsonian Institution, War Department, and from various other sources, as for instance some State observations and so on.

Q. Are those the recognized sources of information that you refer to, the War Department, Smithsonian Institution, etc.?

A. United States Weather Bureau. They are the best, and I may say the only reliable sources of information that are known to me; and other records are to be found in Government publications.

Q. If there were other sources, would you be likely to know them?

A. I think I would.

Q. Have you made any investigations or studies of hy-

draulics or sanitary problems, in connection with any litigation in which you have been engaged?

A. Yes, I was one of the witnesses retained by the City of St. Louis in the State of Missouri, in the case of the State of Missouri *vs.* The State of Illinois and the Sanitary District of Chicago, before the United States Supreme Court, being what is ordinarily known as the Drainage Canal case. My investigations there had particularly to do with the sanitary phases of the case, and latterly with the hydraulic questions of time of flow and the effects of various works in the connecting waters between Chicago and St. Louis.

Q. Are there any other cases with which you have been connected, in which these questions have been involved?

A. I was connected with the case at London, Ontario, involving the general hydraulic problems of back water and damage to millwright properties. I do not recall any other case that I have been connected with in which the sanitary element was important.

Q. Were there any in which water power or hydraulic questions have been involved?

A. Yes, I was engaged in a case here in New York between the City of New York, the New York Water Department and the New York Sugar Refining Company, the water stealing case which involved measurements of water by certain devices.

I was engaged in a case at Kalamazoo, between the City of Kalamazoo and the Standard Paper Company. I believe it was another water stealing case, which involved the measurement of water.

I was engaged in a case between the City of Flint and Mrs. Loranger involving the case of damage to water power by diversion of water.

I was engaged in a case in Illinois involving constructions in the Desplaines River, and their effect upon certain lands.

I was engaged in the case of United States *vs.* the Chandler-Dunbar Water Power Company and the Edison Sault Electric Company and others, to which I have already adverted, which was pretty nearly the essence of hydraulic engineering. And I was also engaged in the case of City of Ithaca *vs.* The Ithaca Water Works Company and others, for the condemnation of Water Works Property, which involved numerous hydraulic problems.

Q. What were the subjects involved in the case of United States *vs.* Chandler-Dunbar Water Power Company?

A. That was a case brought by the United States to acquire the property and lands of the Chandler-Dunbar Water Power Company and the rights of its lessee, the Edison Sault Company in the St. Mary's River, for the alleged purpose of utilizing the said property for the construction of locks in the improvement of navigation. The case involved the determination of the value of the property, and incidental thereto was of course the question of the amount of water power that could be developed there, the fall in the river, the natural and high and low flows and the benefits to navigation and various other collateral items.

Q. Those were the hydraulic questions involved that you just last mentioned?

A. Yes.

Q. Now your practice has taken you over a considerable scope of the country, hasn't it?

A. Yes.

Q. Will you state in a general way what States or cities your practice has involved?

A. I have practiced very largely in Michigan and New York; to a less extent in Illinois, Wisconsin, Minnesota, Massachusetts, both the provinces of Ontario and Quebec, Ohio, Colorado, Dakota, Missouri, and have had occasion to report upon and advise in the construction of works in Arizona, Washington, Pennsylvania. I think that is the list.

Q. Are you familiar with water purifications and the ordinary problems of sewerage, and if you are, state what investigations you have made, or what your practice has been in connection with those problems?

A. I have been for many years interested in the subject of water purification, my attention having first been called to it when I was serving as civil engineer to the Board of Water Commissioners of Detroit; and later I was associated with Mr. Allen Hazen, in the design and construction of a water purification plant for the City of Ithaca, New York, which was built under our supervision. And following that, I designed and constructed for Cornell University a plant for the purification of its water supply; and have been called upon to investigate and examine into various propositions or plans for water supply improvement. I was recently called upon by the Board of Water Commissioners of Detroit to make an examination of the conditions of the Detroit Water Supply, and submitted a report a few weeks ago, which has not yet been published, covering that subject. That involved an in-

vestigation of the lake water supplies in general, including those of Chicago, Milwaukee, Cleveland, Buffalo, Erie, and some of the others.

In the matter of sewage, I have done less. I have designed one or two small sewerage systems, in which case water disposal was used.

I have of course been familiar with the problem of the disposal of sewerage along the Great Lakes, from my acquaintance with it in my birthplace, the City of Saginaw, and later from my extended residence in Detroit, where I was brought into close contact with problems of that nature.

Q. In a general way, how are the waters of the Great Lakes used?

A. The waters of the Great Lakes afford the principal source of water supply for a very large portion of the population resident along their borders. All the large cities on the Great Lakes take their supplies from them or their connecting waters; and these supplies are used for domestic and manufacturing purposes, for the ordinary requirements of urban populations.

They are further used for the purposes of transportation or of navigation. And they are used, at places where circumstances permit, for the development of power; so that you might say that the water of the Great Lakes are used for practically all purposes for which water, natural waters are used.

Q. In your study of the Great Lakes system, and the water supply, have you considered whether there was any relation between the levels of the different lakes?

A. Yes, there is a very marked relation between them, which is influenced in two ways. Beginning with Lake Superior, it discharges through the St. Mary's River into Lake Huron, and any variation in the discharge of Lake Superior will be felt in the amount of water that is received by Lake Huron and Lake Michigan, which are practically one lake; so that a decrease in the flow of the St. Mary's River will have the effect of decreasing the quantity of water supplied to these lakes; and if other conditions remain the same, the lakes will be lower. An increase would raise them, other conditions being the same.

Any change in the levels of Lake Michigan and Lake Huron will be reflected in the discharge of the St. Clair River, which, emptying through Lake St. Clair into Lake Erie, will have the effect of raising or lowering the level of Lake Erie.

Similarly Lake Erie discharging through the Niagara River, if any change in its elevation occurs, it will change the quantity of water flowing through the Niagara, and this in turn will be reflected in the elevation of Lake Ontario, which finally supplies the water to the St. Lawrence River. So that we may say that a change in the amount of water reaching Lake Superior will be felt in the amount of water flowing in the St. Lawrence River.

Then there is, excluding Lake Ontario and Lake Superior, a reflex action. If a large quantity of water be supplied to Lake Erie, for instance, from its drainage area, that will have the effect of raising the lake and thereby decreasing the fall between Lake Erie and Lake Huron, reducing the flow into the St. Clair and Detroit Rivers, and raising the level of Lake St. Clair and likewise Huron and Michigan. So that we may say, so far as the three lakes are concerned, Erie, Huron and Michigan, that a change in one will be reflected in the other; and by reason of the fact that the different latitudes, or slightly different latitudes leads to the melting of the winters snows at slightly different times, and also on account of the storage possible in the lakes themselves, we find that the fluctuations of one lake follow the fluctuations of the other at quite regular intervals; the increase of level of one producing or tending to produce the high water in the one next lower down, at some later period.

Q. Are there any changes in the levels from day to day, month to month or year to year?

A. Very marked changes appear from day to day.

Q. Or from hour to hour, I may ask?

A. Yes, from hour to hour, under certain circumstances, quite extensive vibrations. Changes of one foot or two feet within an hour are not uncommon. And while the average changes from month to month are not so great as that ordinarily, the changes from year to year are considerable, covering a range of some two or three feet on Lakes Huron and Michigan; and I do not recall just the change of stage on Lake Erie at the present moment.

I wish to make a correction there: In speaking of daily changes or hourly changes, they are not changes of stage; they are changes of water at particular points. The monthly changes we call stages.

Q. Those last are sometimes designated oscillations?

A. Oscillations of the lake.

Q. What are the different causes as far as is known, which effect change of stage and oscillation of the lake?

A. The changes of stage are of course brought about by variations in the quantity of water which flows into the lake, and variations in the quantity which flows out. The oscillations are due to the effects of wind and the changes in barometric pressure; the barometric pressure at one end of the lake perhaps being greater than at the other, naturally depresses the surface of the water at that end and causes a rise at the other end. Or the same may occur across the lake. Those effects are, of course, of limited duration, but they cause decided changes of elevation at the extremeties of their effects. As for example on Lake Erie, it is not infrequent, or has not been in the past, that a variation of four feet might occur at one end of the lake; that is, it might be two feet below its natural position or two feet above, and in some cases higher fluctuations than those have been recorded. Those are usually due to the effects of wind sweeping lengthwise of the lake, possibly accompanied by barometric inequalities at the two ends.

I believe there is on record, in fact I know that there is a variation of six feet at the western end of Lake Erie; that is three feet below and three feet above the normal water plane; and that the fluctuations of Erie are sufficient at times to temporarily reverse the flow of the Detroit River so far as the same can be observed by ocular observation. Such occurrences are rare, but one of them has been within my individual observation.

Mr. Wilkerson: Are you able to fix the date of that?

A. It was somewhere between 1893 and 1897, while I was connected with the Detroit Water Works, between 1893 and 1898, I will say.

Mr. Adcock: What is the greatest range of the daily oscillations or changes in level at any particular point of Huron that you know about, Lakes Huron and Michigan being treated as the same lake?

A. I don't think that I can testify from personal observation to a daily change on Lakes Michigan and Huron.

Q. Have you any records or observations made of gauges which would show that?

A. Yes, I have, which would show some. That is, the records are based upon the records furnished from the office of the United States Lake Survey. I find I do not have them in the room; I can produce them later.

Q. Do you know the drainage areas of the different lakes?

A. I know them, yes, as I know other things which are matters of common knowledge.

Q. Do you know what the extent of the areas is?

A. Yes. The drainage area of Lake Ontario, exclusive of the lake itself is about—and that is exclusive of anything tributary to the lake above Niagara, above the head of the Niagara River—is about 25,737 square miles.

Q. What is the area of the lake itself? You might give that at the same time?

A. And the area of the surface of Lake Ontario is about 7,243 square miles. The drainage area of Lake Erie and St. Clair, exclusive of the lakes themselves and of anything above the head of the St. Clair River is about 30,296 square miles.

Q. And the lake area?

A. And the area of the lake surfaces is about 10,471 square miles of which about 500 square miles is in Lake St. Clair. The area of Lakes Michigan and Huron together, or rather, the drainage area of Lakes Michigan and Huron, exclusive of the drainage above Sault St. Marie is about 92,493 square miles, and the area of the lake surface is about 45,314 square miles.

The drainage area of Lake Superior exclusive of the lake surface is about 44,074 square miles and the area of the lake surface is about 32,060 square miles.

The land drainage area of Lake Michigan is about 43,463 square miles and the area of the water surface is about 22,336. The land drainage of Lake Huron is 49,710 and of the water surface 22,298.

Q. How is the water supplied to the Great Lakes?

A. The water supplied to the Great Lakes comes directly on to their drainage areas, and on to their surfaces as rainfall.

Q. Sometimes called precipitation?

A. Sometimes called the precipitation. And the source of this supply is probably to a very large extent the Atlantic Ocean and the Gulf of Mexico. In fact whatever is contributed to the ocean through the St. Lawrence River must be brought back in the form of rainfall and redeposited upon the drainage areas; otherwise the lakes would run dry and the ocean would fill up and drown out all the land.

Q. That would be true also of any water supplied to the Gulf of Mexico, wouldn't it?

A. Yes.

Q. Has there been any measurements of rainfall from time to time in the last period of years by any one?

A. The measurements of rainfall have been carried on at various places on the drainage areas of the Great Lakes for a great number of years. In the early days, these measurements were taken usually by individuals who were interested in the subject; and search of the old records will find in almost all our larger cities the history or record of some one who kept rainfall observations for a greater or less time. These observations were taken up by the United States Government along in the late sixties, I think, or indirectly the Smithsonian Institution apparently either collected the records from various sources or exercised some charge over their collection. Then there was for a time a so-called United States Weather Service which was later incorporated or transferred to the corps of engineers of the United States Army. I think not to the corps of engineers but the officers at United States army posts were expected to take and report rainfall observations.

Later, the present Weather Bureau was organized and since that time a systematic, a more systematic administration of rainfall and general meteoriological observations has been kept up. These observations, as we meet with them now, are comprised in perhaps three classes: First, and best, those taken by the regularly established weather bureau stations, which are located in most of the large cities and in some other strategic points, you might say, throughout the country.

The next in order is the record of various observers who have worked or are working under the authority of various states; there having been in several of the states a weather service at one time or another, and in some I believe it is still continued.

Then beyond that, and that upon which we are to a large extent dependent for the rainfall in the more remote regions, is the records prepared by you might say a vast army of volunteer observers. The United States Weather Bureau encourages any one who is interested in the observation of rainfall, temperature, evaporation or anything of that sort, by furnishing them now with a set of standard instruments for the observations which they are preparing to take, and asking that they make reports monthly to the Section Director of the Weather Bureau Service, in the particular state or region where they are located. In that way a large amount of information is gathered from localities which could not be reached or represented by the stations at which paid observers are

maintained. And still there is undoubtedly a large margin of error in this, as the observer will be found frequently to neglect to observe for a month or two here and there, or probably they oftentimes omit days of rainfall and so on, still taken as an average the country over it is probable that the relative values are reasonably correct. That is, we have no reason to suppose that observers in Minnesota would be any less lax or more lax than those in the State of New York; and that when we take the result of the observations of a large number of these observers and compare them with the results of a large number in some other locality, the relative indications we may assume to be quite reliable while the absolute indications, that is as to the actual amount, may be very largely in error.

The observations of the United States observers themselves, I think we are safe in saying, are quite accurate for the places where they are observed, but of course they do not cover the entire region by any means, and only represent accurately as to time a comparatively small area; though when considered as the mean of a year, the mean rainfall indicated for a year by these government observations, it is probably—I may say thoroughly representative of the mean rainfall for the region, unless you happen to meet with those conditions which change the character or the amount of precipitation, such as a mountain range or range of high land, or proximity to a large body of water.

For example, in the State of Michigan, the western side of the state receives appreciably more rain than the eastern side. That appears to be due to the fact that the rain mainly comes up through the Mississippi Valley from the Gulf of Mexico, and the western side of the state gets it first.

It is also noticeable, that where a mountain range intervenes between the source of the water in the atmosphere that the side away from the source will be dry and the side towards the source will receive much more rainfall. That is particularly noticeable in the western part of the United States, where the area between the coast range and the Pacific is supplied very bountifully with rainfall; after you pass the coast range, there is less, and by the time you get past the Sierras, you have practically a sterile—practically a desert, except at times of melting snow.

Q. What becomes of all this rain that falls upon the drainage area and the lake surfaces of the lakes?

A. The rain which falls upon the drainage area, upon the

land area, is disposed of usually, we say, in three ways: By evaporation, that is, the evaporation, by surface run-offs, and by percolation. A large part of it, in fact more than half, is re-evaporated either through the direct action of the rays of the sun upon the particles of water, as they lie upon the surface of the earth, or the branches and leaves of the trees and so on, or may be through the agency of the trees and vegetation itself, which takes up the moisture from the soil through its roots, passes it through its stem in the form of sap and exhales it from its leaves in the form of moisture.

The evaporation of different plants is markedly different; some apparently evaporating three or four times as much as others. The rain that falls upon the earth's surface in times of heavy downpours, or when the surface is frozen, or in the time of thawing of snows in the spring—or rather I should say that is on the surface under those conditions, a considerable portion flows off from the surface as visible run-off, as we see it in the ditches along the side of the road and in the small streams which you notice flowing through the fields, after heavy rains. It flows off into the rivers, creeks, and ultimately to the Great Lakes and to the ocean, speaking of the drainage of the Great Lakes.

Another portion, depending very largely upon the character of the soil, and to some extent on the character of the vegetation, finds its way into the soil and flows through it and furnishes the water supply which we ordinarily obtain from wells, either shallow or deep. This water, to a large extent, appears to return to the streams themselves and influences the discharge or the run-off as we call it, that is measured as surface run-off. Some of it of course reaches the Great Lakes through their sides and through the bottom, but——

Q. That is called subterranean passages, isn't it?

A. We hardly would call it subterranean passages, because there is really no passage in the sense of its being a channel or conduit, but it is simply the gradual percolation of the water through the sands and between the grains of the soil. And while it has never been possible to measure the amount of that flow into the Great Lakes, such information as is available on the subject, namely, as to the yield of wells which have been put down along the lake shore at various points where the supply comes from this current of water that is moving slowly through the earth, indicates that the amount of that run-off to the Great Lakes must be small.

Mr. Wilkerson: That is entirely in the realm of speculation, isn't it?

A. No, I don't think it is entirely. No, I think we have good reason to come to the conclusion that the amount reaching the Great Lakes through the underground surface is relatively a very small factor.

Mr. Adcock: Is there in your experience and from the records which you have examined, can you state whether there is any relation of evaporation to rainfall?

A. There is a relation, or there are certain relations. The law connecting rainfall and evaporation has not yet been worked out, and it is one of the most complicated problems that is to be encountered. Some of the conditions which must be included in the statement of any such law are quite well understood.

In the first place, as I have already said, rainfall falling upon the ground when it is frozen will run off very rapidly into the water courses, and a very large per cent. of it will appear as run-off. Rainfall falling on a sandy area which is not frozen will to a very large extent be absorbed by the earth; will pass through in the form of percolation to the streams which drain that area, and will ultimately reach the Great Lakes. The rainfall falling upon a cultivated area, at times when crops are growing, will to a very large extent be re-evaporated by the crops, and of course would appear in the atmosphere.

The evaporation is influenced by temperature, and by the wind, and by the amount of moisture in the air, so that we are pretty safe in saying that during a rain there is not much evaporation, so that it follows if you have, for instance, say three inches of rainfall in a month distributed in small showers, so that it covers a large number of hours, that is .02 of an inch at a time, perhaps the evaporation from water surfaces would be materially less, very much less under those conditions than it would be if it came in one or two large showers and evaporation was allowed to continue during the intervening periods, or would continue, as it must, without interference. That is one of the things that makes it extremely difficult to correlate the amount of rainfall with the amount of run-off or the amount of evaporation, because the same amount of rainfall delivered in one way may be productive of a very relatively large amount of run-off, whereas delivered in another way it nearly all goes off in evaporation and you have very little left in the run-off.

The comparisons of run-offs of various streams in Michigan which I have studied for a number of years show a quite wide variation in the amount of water—in the percentage of rainfall that appears as run-off; those streams coming from sandy areas giving relatively large run-offs; those streams coming from highly cultivated areas giving small run-offs.

The comparison of the streams in the west, that is, in the Central States with those further east, say in Central New York, where the country is much more precipitous indicates that the percentage of run-off in the New York streams is considerably greater than that in the Michigan and Wisconsin and Illinois streams, by reason of the fact that the rain that falls flows quickly into the streams and is carried off quickly before it has time to evaporate. There are all those conditions that have to be taken into account. For example, the run-off from the State of Ohio is noticeable for its smallness relatively to the others. The high cultivation apparently, combined with the character of the soil, which is a loam, and with the character of the surface, which is moderately rolling, seems to conduce to a very high evaporation or a very large absorption by plant roots, and subsequent evaporation so that the run-off from the Ohio streams, both those which flow into Lake Erie and those which flow into the Ohio River, is considerably less than is run-off of those streams that flow into Lakes Michigan and Huron, or into Lake Ontario.

Q. Is there any difference in evaporation of different drainage basins of the Great Lakes, drainage areas of the Great Lakes?

A. Yes, there undoubtedly is. Such observations as have been made indicate such to be the fact. And there appears to be a larger evaporation from the basin of Lake Erie than from either that of Ontario or of Michigan and Huron; and the evaporation from Lake Superior, though the observations are less complete than elsewhere, appears to be materially less than that from the lakes lower down, which is of course to be expected on account of the general lower temperature, both of the air and of the water.

Q. As a result of the evaporation taking place more rapidly in the summer time, when is the lowest stages of the lakes usually, during the year?

A. They are usually in the fall or winter, if I remember rightly; rather in the winter, for the lake stages during the navigation season are in general higher than they are during

the average of the whole year. In general the low period is in February and March; that is the late winter.

Q. You are referring now to what?

A. Complainant's Exhibit 5.

Q. Has the run-off of the various rivers supplying the lakes been measured in any way?

A. Run-off observations have been taken covering periods of years on a large number of rivers flowing into the Great Lakes. These observations are largely compiled by the United States Geological Survey, although the observations covering the New York streams—a very considerable amount of information covering those streams is to be found in the reports of the State Engineer of New York, and some other sources; the report of the Board of Engineers on Deep Waterways contains a discussion of them.

From an examination of that information and other information, with which I was personally familiar, I find that run-off observations have been taken covering about 37 per cent. of the drainage area of Lake Ontario; about 33 per cent. of the drainage areas of Lakes Erie and St. Clair, and about 32 per cent. of the drainage areas of Lakes Huron and Michigan, all being exclusive of the drainage areas of the lakes next above. The run-off observations of streams supplying Lake Superior are limited to one or two streams, and are too limited to give any very definite information.

Q. We have heard a good deal about the terms "increment," Mr. Williams. I would like to ask you to define that word if you can?

A. The term increment as used in this case has a peculiar significance. As used in general, it means any change or increase of a changing quantity. In this case it means a specific change or the amount of change in the discharge of one of the rivers—of any of the rivers that is due to an increase of elevation of one foot in the controlling lake. So that when we use the term increment here, we mean the amount of water by which the flow of the river in question would be increased by the rise of one foot in the lake which is supplying the water or which is controlling or assumed to control the discharge.

Q. Is it applied in the same way to the lowering of one foot?

A. Yes. It is the amount of water by which the discharge would be changed by a rise of a foot or the fall of a foot, and for the purposes of this case within the range it has been used, it has been assumed that the increment due to a rise of

a foot is the same as the increment due to the fall of a foot; and the observations show that to be substantially correct, while absolutely or theoretically it is not.

Q. For all practical purposes it is the same?

A. For all practical purposes, within the ranges that are dealt with in this case, it is the same; or within the ranges that have been dealt with thus far in this case.

Q. So that you, in using the term increment, you refer to the increment say of the St. Clair River, Detroit River or Niagara or St. Lawrence Rivers?

A. Yes.

Q. Why is it necessary, in connection with the investigations that have been made to determine the effect of a diversion of water, say at Chicago, why is it necessary to obtain an increment of, say the St. Clair River?

A. Because that is the only way in which the effect of a diversion of the magnitudes considered could be determined. The magnitude of the diversion is so small as to be insusceptible of any direct observation or measurement; and the only way in which a measure of its effect can be obtained is by ascertaining how much the flow would be increased or decreased by the change of a foot. Then conversely the change of so much flow would change the level a foot, and of less than so much would change it a proportional part of a foot.

Q. Do the fluctuations of, say, the controlling lake have any relation to the increment of the outlet of that lake?

A. Yes, they are very intimately related considering or dealing with the changes of stage over a considerable period of time as a year, for instance. The greater the change of stage in annual fluctuation, or in fluctuation from year to year, the less must be the increment, and vice versa, a lake which changes but slightly in its surface elevation gives indication of a large increment and one which changes greatly gives indication of a small increment of the quantities of water flowing into the two lakes, is reasonably near the same amount. If, for instance, a lake having a smaller quantity of water shows a higher fluctuation than a lake having a larger quantity of water flowing into it, the indication is conclusive that the increment of the lake which shows the higher fluctuation is less than the increment of the lake having the lower fluctuation.

This can perhaps be illustrated by taking a trough and putting two partitions in it, and allow water to flow down it. If you have an opening in one partition that is, say, four inches square, and an opening in the other partition of the same size,

if you raise the water in the upper section of the trough, in a reasonable time it will rise correspondingly in the lower section. But if in the lower section there is an opening which, let us say, is four inches deep and eight inches wide, the water in the lower section will not rise as high, in fact actually something less than half as much as it is raised in the upper section.

In other words, the increment of the discharge through the lower partition is more than twice as great, for these exact figures, than the increment of discharge of the upper section. So that it follows that the relation of the increment is inversely as the relation of the fluctuations.

In other words, you can say if the fluctuation of one lake is twice as great as the fluctuation of the other, then the increment of the first lake must be about half as great as the increment of the other.

Mr. Wilkerson: You are speaking now with reference to continuous flow?

A. I am speaking now with reference to continuous flow.

Mr. Adcock: So that if you found in one period of a number of years the fluctuations of a particular lake, like Lake Huron, for instance, were greater than another period of years, it would be assumed that the increment had changed?

A. I think that would be conclusive evidence, if both covered reasonably long periods. I would not say that a comparison of fluctuations for one or two years would be sufficient, but if you had 15 or 20 years in a period, I think you would be quite safe in drawing that conclusion.

Q. When you refer to fluctuations of the lake in connection——

A. I mean real change of stage for considerable periods of time.

Q. Real change of stage, and yearly fluctuations?

A. Yes, from year to year.

Q. Not of monthly?

A. Not the monthly.

Q. Why do you eliminate the monthly fluctuations in connection with determining the relation of the increment?

A. Because in the monthly fluctuations there is not time for the effect of the storage in the lakes to work out. It takes time for the lake to rise, and if you deal with monthly fluctuations, one lake would not have yet followed the other closely enough to warrant a judgment. That is, your second lake

would be lagging too far behind the first one, so that you might be misled in your conclusions.

Q. Is there any relation between the increase of the increment and the discharge of the river?

A. Yes, that depends upon the form of the channel to some extent, but it may be demonstrated by the ordinary laws of hydraulics and physics that the change of increment cannot be greater than the change of discharge. That is, that if you have a certain channel which has a certain increment, and by changes in that channel made below the surface of the water you increase the increment, you must have increased the discharge in at least as great a proportion.

Q. Why do you say in at least as great a proportion?

A. Because that is the limit. They could only be equal in the case of an extremely large channel, with an extremely small change, but in any change that becomes appreciable the magnitude of discharge will be changed to a greater extent than the increment is changed.

Recess to 2 p. m.

After recess—2 p. m.

GARDNER S. WILLIAMS resumed the stand and testified further as follows:

Mr. Adcock: From your study and experience have you become and are you now familiar with navigation upon the Great Lakes?

A. Yes, I have been familiar with the conditions of navigation and with navigation for the greater part of my life.

Q. What is the general course of travel, of boats carrying freight upon the lakes, the Great Lakes?

A. The largest part of the traffic of the Great Lakes above Ontario is composed in tonnage, the largest part in tonnage is composed of ore.

Q. That is iron ore?

A. Iron ore. This traffic originates mainly at Lake Superior ports; Superior, Duluth, Ashland, Marquette.

Q. You are referring now to Complainant's Exhibit 6?

A. Complainant's Exhibit 6.

Q. Entitled "General Chart of the Great Lakes?"

A. General Chart of the Great Lakes. It passes through Lake Superior, the St. Mary's River, and divides, a small

portion of it going to the Straits of Mackinaw to South Chicago; and by far the largest portion going through Lake Huron and St. Clair River, Lake St. Clair and the Detroit River to Lake Erie ports, Cleveland and Ashtabula particularly.

There is also a considerable amount of ore from Escanaba, which is at the northern end of Green Bay. This passes out into Lake Michigan and divides, a portion of it going to South Chicago down to Lake Michigan, and the other portion passing eastward through the Straits of Mackinaw, and joining the traffic from Lake Superior on its way to the Lake Erie ports.

Q. What is the traffic below Lake Erie, or from Lake Erie to other points?

A. Going down from Lake Erie, the depth of navigation is controlled by the depths of the Welland Canal, first which connects Lake Erie and Ontario; and then by the depth of the Canadian canals along the River St. Lawrence, so that it follows that deep draft boats are not in use on Lake Ontario; and in 1911 there was no boat on Lake Ontario drawing more than 14 feet.

Of course in addition to this ore traffic, there is a large passenger traffic, and a considerable traffic, in package freight, which moves in both directions, up and down through the lakes. And a traffic in coal northward at certain seasons of the year which moves from the Lake Erie ports to ports along Lake Superior and Lake Michigan. This coal traffic is largely carried by the ore boats on their return trips; and there are comparatively few boats used in it alone and the draft of their boats is very much shallower than that of the ore carrying boats. I have a memorandum of that, I think, which I took the other day. A few days ago I examined the boats of the Detroit & Cleveland Navigation Company that were tied up at Detroit. These embraced the two largest boats of the fleet, the City of Cleveland Third, and the City of Detroit Third, upon which the highest marks were for 15 and 16 feet. Those were at the stern. The bow marks were 14, in the case of the City of Cleveland. I was in error in stating that 16 was the highest on the Detroit. The stern mark on the Detroit was 17. The City of Mackinac and City of Alpena, both being "Second" so-called, which ply from Detroit to Mackinac, at their sterns were marked 11 and 12 respectively.

Q. That is feet?

A. That is feet. And it is not customary for those boats to load beyond their marks, as I have seen them many times

and I have never seen them when the marks were obscured. In fact they could not load lower than that, without interfering with their paddle boxes.

Q. Now you have described in a general way the course of travel of the boats, of the freight carrying boats. I have here a chart marked "Lake Superior," issued by the United States Lake Survey. I ask that it be marked Defendant's Exhibit 1 of this date.

(Whereupon chart referred to was marked Williams Exhibit 1, March 18, 1913.)

Q. What does that chart show?

A. That chart shows the geography and hydrography of Lake Superior, the outline of the lake and the immediate shore topography is shown and also the depth of water at various places throughout the lake, where soundings are indicated by figures, and also the courses of navigation, which are indicated in general by dotted lines from point to point along the lake.

Mr. Wilkerson: These small figures are depths?

A. They are depths in fathoms.

Mr. Adcock: How much is a fathom?

A. Outside of the blue, the depths are in fathoms of six feet. Inside the blue the depths are in feet.

Q. Now a boat, an ore boat, for instance, passing from Marquette out of Lake Superior, at what point does such a boat leave Lake Superior?

A. At the head of the St. Mary's River; that is it enters St. Mary's River.

Q. Is there a bay called Whitefish Bay?

A. Whitefish Bay.

Q. Now, I show you another chart issued by the United States Lake Survey, which I ask be marked Williams Exhibit 2 of this date, entitled "Chart 3. St. Mary's River." From that chart, Mr. Williams, can you indicate or state what course a boat will follow going down through the St. Mary's River and the lakes?

A. It will come into the head of St. Mary's River from Whitefish Bay and follow down through the deep water in the river, angling to the left above Round Island, and following the river down to a point about two miles about the locks, where it may choose between taking the Canadian Channel to the northward, or coming through the American locks, which are on the south side of the river at the Falls.

Q. When you say Canadian Channel, you mean also Canadian locks, don't you?

A. I mean also the Canadian locks; passing through the canal either on the Canadian side or the American side. It then passes into the lower river and proceeding down below the City of Sault Ste. Marie it has a choice of taking the Canadian Channel or the American channel. The practice at present is for the loaded boats to take the American channel I believe. The Canadian channel, the Lake George Channel communicates with the Georgian Bay, and is used mainly by boats plying in that direction?

Q. Is the depth of the water indicated on this chart by the figures?

A. It is indicated on this chart in feet.

Q. All the way in feet?

A. Yes, sir, apparently all the indications are in feet.

Q. In the blue as well as the white?

A. Both in the blue and the white.

Q. I show you another chart issued by the United States Lake Survey entitled "St. Mary's River. Chart 2," which I ask be marked Williams Exhibit 3 of this date. In a general way what did that chart show with reference to the St. Mary's River and the channel there?

(Chart shown to witness and marked Williams Exhibit 3, March 18, 1913.)

A. That chart shows the river below Sault Ste. Marie, or practically from the lower end of Sault Ste. Marie to Mud Lake.

The Lake George Channel is seen in the northern end of the chart, going into Lake George and thence out to St. Joseph Channel into Georgian Bay. The main improved channel from Sault Ste. Marie to Hay Lake is close to the American shore, and below Hay Lake the channel divides, one passing down through the West Neebish, and the other to Mud Lake, or through Little Mud Lake, and the two uniting in Mud Lake Proper.

Q. What does the blue on that map indicate?

A. The blue indicates shoal water, and the white indicates water deeper than 21 feet.

Q. Now take the course of the boat from where you left off on the other chart.

Mr. Wilkerson: Is that same thing true of the preceding charts?

A. That is true of all of them until you get to Ontario.

Mr. Adcock: Will you state what course the boat would follow in its downward course?

A. The loaded boat would pass down into Hay Lake through the main improved channel on the American side and then take the right-hand or western channel through the West Neebish; the eastern channel through by way of Sailors' Encampment, Little Mud Lake being reserved for up-bound boats. From Mud Lake the channel passes or the course passes through the lake southeasterly to the next chart.

Q. Which is Chart 1, which I have in my hand, which may be marked Williams Exhibit 4 of this date, entitled, "Chart No. 1, St. Mary's River." Now will you state in a general way what that chart shows?

(Chart shown to witness was marked Williams' Exhibit 4, March 18, 1913.)

A. That chart shows the lower end of the St. Mary's River with the outlet into Lake Huron. The course from Mud Lake is bearing southeastward and then turns almost due south and then to the eastward again; finally south through the Detour Passage.

Q. Is the depth of water indicated on that chart in the same manner that it is on the other charts that you have mentioned?

A. Yes, the indication here is in feet, both in the blue and in the white, and the blue represents water less than—the white represents water 21 feet in depth.

Mr. Wilkerson: How far is it from the falls down to Lake Huron?

A. I don't remember, but about 40 miles.

Q. About 45 miles?

A. I may add that the St. Mary's River enters Lake Huron a comparatively short distance east of the Straits of Mackinaw.

Mr. Adcock: I show you another chart here entitled, "Lake Michigan," issued by the United States Lake Survey, and ask that it be marked Williams' Exhibit 5 of this date. What does that chart show?

(Chart shown to witness was marked Williams' Exhibit 5 March 18, 1913.)

A. That chart shows Lake Michigan, including Green Bay and the Straits of Mackinaw. It does not extend quite over to the mouth of the St. Mary's River.

Q. Boats bound for Chicago and points at the lower end of Lake Michigan, what course would they take?

A. They would pass westward through the Straits of Mackinaw and may then pass west to the westward of Beaver

Island, or the Beaver Island group, in which case they will have a good depth of water; or they may take the passage to the east of the Beaver Island group, which is somewhat narrower, but involves a shorter distance. This permits them to pass either east or west of the Manitous, and down Lake Michigan.

Q. Is the depth of water indicated there upon the map in fathoms or in feet, by the figures?

A. That is indicated in fathoms in the white and in feet in the blue.

Q. Take the boats going from Escanaba to South Chicago, will you describe their course?

A. Escanaba is on the northern arm of Green Bay. A boat would pass south in Bayde Noch and then southeasterly through some one of the passages between the islands which divide Green Bay from the main lake, and then southward the length of Lake Michigan.

Q. Will you describe the course of those boats which are going from Escanaba to Cleveland, say?

A. They would pass eastward, as soon as they pass out of Green Bay, and pass through the Straits of Mackinaw, either by going north of the Beaver Island group or south of it.

Q. Here is a similar chart entitled "Lake Huron," which I ask to be marked Williams' Exhibit 6 of this date. State in a general way what is shown on that chart.

(Chart shown to witness was marked Williams' Exhibit 6, March 18, 1913.)

A. That chart shows the outlet of the St. Mary's River, or the mouth of the river, Georgian Bay, or the north channel, more properly called, and Georgian Bay lying to the eastward, and Lake Huron; also the Straits of Mackinaw in the northwestern corner of the chart.

Q. Is the depth of water indicated there in fathoms or in feet?

A. The depth of water is indicated in fathoms in the white and in feet in the blue.

Q. Now will you describe the course of a boat going from the St. Mary's River to the St. Clair River?

A. Coming out of the St. Mary's River it bears somewhat easterly of south, perhaps south southeast, and the line is very nearly straight, having a slight curvature to the eastward.

Q. At what point?

A. I mean it is very nearly straight from here to the mouth of the St. Clair River, having a slight curvature to the east to

avoid the region in the vicinity of Alpena and again at Sand Beach.

Q. I have here a similar chart entitled "St. Clair River," which may be marked Williams' Exhibit 7. Will you indicate what is shown on that chart in a general way?

(Chart shown to witness was marked Williams' Exhibit 7, March 18, 1913.)

A. That chart shows the St. Clair River from Lake Huron to Lake St. Clair. It is made up in two principal sections, one reaching from Lake Huron to the town of St. Clair and the other reaching from Stag Island, or from the foot of Stag Island, which is above St. Clair, through the delta into Lake St. Clair.

Q. How is the depth indicated on that map?

A. The depth is indicated in feet both in the white and in the blue.

Q. And the course of a boat going to Cleveland would be what, through the St. Clair to Lake Huron?

A. It would enter the St. Clair River at Fort Gratiot, and pass down the river following the main channel to a point opposite Algonac, when it takes the so-called "South Channel," or what is now known as the main channel through the St. Clair Flats Canal and out into Lake St. Clair following the dredged cut across Lake St. Clair.

Q. How many channels are there there which boats may take?

A. Through the Flats, or through the canal proper there are two channels, one used for down-bound and the other for up-bound traffic.

Q. How wide are these channels, do you know?

A. One of them is 290 feet and the other is 300 feet wide.

Q. Do you know the width of the St. Clair River from Huron down to the St. Clair Flats?

A. It is something less than 2,000 feet in the narrow portion, but generally between 2,500 and 3,000 feet. There are places where it is somewhat wider.

Q. Then from the St. Clair River, or St. Clair Flats, boats pass through—

A. Lake St. Clair.

Q. Lake St. Clair, which is shown on the chart entitled, "Lake St. Clair," similar to the ones which have been introduced in evidence, which I ask to be marked Williams' Exhibit 8. Now, Mr. Williams, what in a general way does that chart show, the one to which I have just referred?

(Chart shown witness marked Williams' Exhibit 8, March 18, 1913.)

A. That shows the outlet of the St. Clair River, or the lower end of the St. Clair River, beginning at a point about six or seven miles above Algonac and extending through Lake St. Clair to the head of the Detroit River.

Q. How is the depth of water indicated there?

A. The depth of water is indicated here in fathoms in the white and in feet in the blue.

Q. What would be the course of a boat going down on its way to Cleveland, say?

A. (No answer.)

Mr. Wilkerson: When you speak of the course of a boat, you mean the straight cut, so to speak, in fair weather, and not the course it might be obliged to take in the time of storms or when meeting with an accident that obliged it to lay up some place for repairs; you mean the straight cut?

Mr. Adcock: The ordinary course.

Mr. Wilkerson: In fair weather.

Mr. Adcock: Simply in a general way, the ordinary course so that it can be followed through.

A. The boat passes out of the St. Clair Flats Canal and through the dredged cut, which is something less than two miles in length into the deep water in the middle portion of Lake St. Clair. Then it passes in an almost straight line—

Q. In a general way, how deep is that water in the middle?

A. The water runs about 3½ fathoms, it is about 21 feet below the reference plane of this chart.

Q. The reference plane is what?

A. The reference plane of this chart is elevation 575.16 above sea level, which is about a foot and a half above the lowest monthly mean water as indicated on this chart.

The boat then passes into what is known as the Grosse Point Channel, which is six miles or five miles in length, perhaps, which is dredged through the shoal at the lower end of Lake St. Clair.

Q. Is the Grosse Point Channel indicated by any terms on that map?

A. The Grosse Point Channel is indicated by the white channel through the blue at the lower end of Lake St. Clair. It lies just north of a deep blue patch indicated as Grosse Point dumping ground, which is where material from the channel was wasted at the time the channel was built or constructed. And that takes them into the head of the Detroit River,

in the vicinity of Windmill Point and Isle Lopesch, which has been translated in the vernacular into Peach Island.

Q. At that point you enter the Detroit River?

A. The Detroit River.

Q. Which is shown on a similar chart entitled "Detroit River," Williams' Exhibit 9. That shows the Detroit River, does it, Mr. Williams?

(Chart shown witness marked Williams' Exhibit 9, March 18, 1913.)

A. That shows the Detroit River.

Q. From the head of St. Clair?

A. From the foot of Lake St. Clair at Windmill Point down past Belle Isle, City of Detroit, turning to the southward, passing by numerous channels, past Fighting Island and Grosse Isle to the region known as the Lime Kilns or Ballard's Reef, which constitutes the line of demarcation between Lake Erie and the river.

Q. How is the depth of the water indicated there?

A. The depth of the water is indicated on this chart in feet, in all cases.

Q. Both in the blue and the white?

A. Both in the blue and the white; the white indicating depth above 18 feet below the reference plane. The reference plan of this chart is 573.11, which is about 2½ feet above the lower recorded monthly mean as indicated on the chart.

Q. What do the new charts refer to?

A. In the right-hand portion of this chart is shown the Lower Detroit River to a larger scale, but this is more clearly shown on another chart.

Q. Entitled "The Lower Detroit River"?

A. Yes, entitled "The Lower Detroit River."

Q. What is the width of the Detroit River above Fighting Island?

A. Well, it is from 2,200 to 3,000 feet at most places.

Q. What is the width of the channel at Belle Isle, to the right of Belle Isle?

A. Opposite Belle Isle is a little over 2,000 feet wide on the Canadian side. It is considerably wider on the American side, but the channel is not so deep, and it is not used for navigation except by boats having local freight to take on or deliver at the docks along the front of Detroit, above the foot of Belle Isle; and by some passenger boats.

Q. So that the course of the boat would be on the Canadian side of Belle Isle?

A. Yes, passes to the south of Belle Isle.

Q. Then it would follow the channel down from Belle Isle to Fighting Island?

A. Follows the channel from Belle Isle to Fighting Island, passes to the westward of Fighting Island, to the eastward of Grosse Isle; then down through the Lime Kilns, or now through the Livingstone Channel into Lake Erie at Bar Point.

Q. I show you a chart here entitled "Lower Detroit River," which I ask to be marked Williams' Exhibit 10. I will ask you to state what that chart shows?

(Chart shown witness marked Williams' Exhibit 10, March 18, 1913.)

A. That chart shows that portion of the Detroit River lying to the eastward of Grosse Isle, from a point about a mile and a half above the head of the Livingstone Channel to Lake Erie. It is designated "Lower Detroit River," showing Livingstone Channel.

Q. From Stony Island down, what course would the boats follow generally, the ordinary course?

A. Down-bound boats at the present time are supposed to use the Livingstone Channel, which goes almost directly south from a point a short distance above Stony Island, while the up-bound boats take what is known as the Amherstburg Channel, or was formerly called the Lime Kiln Channel, which is to the right of Bois Blanc Island.

Q. Where is Ballard's Reef shown, if at all, on that map, that chart?

A. Ballard's Reef is shown at the top of this map. It is marked "Ballard's Reef" in the line of the main channel.

Q. And where is what is called the Lime Kiln Crossing?

A. The Lime Kiln Crossing is pretty nearly opposite Stony Island, a little bit to the south. It does not seem to be marked.

Q. Well, what points does it cover, can you indicate on the map?

A. The Lime Kiln is represented almost as being in the range of river that is covered by the coffer dam of the Livingstone Channel, which is indicated here parallel to the side of the main channel.

Q. Do you know how the elevation of Lake Erie compares with the elevation at the Lime Kiln Channel, what relation they have?

A. Well, ordinarily the elevation of Lake Erie is slightly lower than that at the Lime Kiln. I think there is about a fall of possibly, ordinarily, something around five inches.

Q. Is there a gage at Amherstburg, has it been maintained for some years?

A. There is a gage maintained at Amherstburg, and at times a gage has been read known as the Lime Kiln gage, which is opposite about the middle of the Lime Kiln or the lower end of it; also there have been numerous other gages at different times located along the river here; one at Mamajuda Light, which is at the upper end of this particular chart, which has been observed at times.

Q. Do you know the widths of the Lime Kiln channel as it exists today, at the present time?

A. The Lime Kiln Channel at the present time is 600 feet wide in its narrowest portions.

Q. That is the channel that the down-bound boats take?

A. No, that is the up-bound at present. It is the old channel.

Q. And the Livingstone Channel, what is the width of that?

A. The Livingstone Channel is 300 feet wide in its narrowest section, which is through that part of the rock that was excavated in the wet. Through the rock which was excavated within the dry, within the coffer dam, it is 450 feet wide, and down in the soft material it is widened to—I think gradually widens to about 1,200 feet.

Q. Will you indicate on the map where it was excavated in the soft and in the wet, and where the coffer dam is?

A. The coffer dam extends from a point practically opposite the upper end of Stony Island south for a distance—south, or down the river, for a distance of about 6,000 feet. Then comes the rock section which extends from this point—

Q. That was excavated in the wet?

A. That in the coffer dam was excavated in the dry. The lines of the coffer dam are shown here extending from Stony Island down to the—

Q. To a point indicated by—

A. Indicated by Light No. 6, Lights Nos. 5 and 6, which are on the west and east sides of the Livingstone Channel respectively, at the foot of the coffer dam.

Q. Then how far does that portion of the channel extend, which was excavated in the wet that you mentioned?

A. In the rock?

Q. In the rock.

A. That extends from the foot of the coffer dam to a point practically opposite Bar Point, and has a length of about 3½ miles. We then come to the portion which was excavated in earth, which extends for another four miles about, or 3¼, into the lake.

Q. Before the Livingstone Channel was constructed, was

that portion of it that is now Livingstone Channel earth or water except where it was excavated?

A. It was water, but in many places quite shallow. At some points the water was not over four feet deep, at ordinary stages through the section where the channel now has been excavated.

Q. I show you a similar chart here which is entitled "Lake Erie," and ask that it be marked Williams' Exhibit 11 of this date. In a general way what does that chart show?

(Chart shown witness marked Williams' Exhibit 11, March 18, 1913.)

A. That chart while showing primarily Lake Erie also shows the foot of Lake Huron, the St. Clair River, Lake St. Clair and the Detroit River, to a rather small scale, but indicating their relative positions with reference to Lake Erie.

Q. How is the depth indicated on that?

A. The depth is indicated upon this chart in fathoms in the white and in feet in the blue.

Q. Now, will you indicate the ordinary course of boats going to Cleveland from the Detroit River, after they pass through the Detroit River?

A. Coming out of the Detroit River the boat bears a little south of east and passes through the passage between Pelee Island and Point Pelee and then bears directly into Cleveland Harbor.

Q. Is the Welland Canal indicated on that map?

A. Yes, the Welland Canal. This map also shows the Niagara River and the upper end of Lake Ontario. It shows the Welland Canal starting at Port Coburn on Lake Erie, and extending through to Port Dalhousie on Lake Ontario. It is located to the westward of the Niagara River.

Q. Do you know in a general way the freight that is carried to and from Buffalo or other harbors about Lake Erie?

A. I don't know the exact magnitude of freight that is carried to Buffalo. It is made up now largely of package freight and some grain. But the transportation of grain on the Great Lakes has been decreasing of late years, so that it is of less importance than it was some years ago.

Q. I show you a chart entitled "Buffalo Harbor," similar to the charts that have been introduced, and ask that it be marked Williams' Exhibit 12. What is indicated on that chart?

(Chart shown witness marked Williams' Exhibit 12, March 18, 1913.)

A. This chart shows the lower end of Lake Erie and the

Niagara River as far down as Niagara Falls. It also shows the start of the Erie Canal, bearing eastward from the river at Tonawanda.

Q. How is the depth indicted there?

A. The depth in this case is indicated in feet, both in the white and in the blue.

Q. What traffic is there on the Niagara River?

A. It is very insignificant, mainly passenger traffic except that which passes into the Erie Canal which really is not in the river.

Q. Do you know the depth of the Erie Canal?

A. The Erie Canal is being developed for barges 12 feet in depth.

Q. And the Welland Canal you stated to be what?

A. About 14.

Mr. Wilkerson: What do they call that canal? They are reconstructing it, aren't they?

A. New York State Barge Canal.

Mr. Adcock: I show you a chart here entitled "Niagara River," which has been marked Williams' Exhibit 13 of this date, and ask you to state what that shows.

(Chart shown witness marked Williams' Exhibit 13, March 18, 1913.)

A. That shows the Niagara River from the pool above the falls to Lake Ontario, and a small portion of Lake Ontario at the outlet of the river. The depths are marked in feet, both the white and the blue.

Q. I show you a similar chart entitled "Lake Ontario," which I ask to be marked Williams' Exhibit 14, and ask you to state in a general way what it shows.

(Chart shown witness marked Williams' Exhibit 14, March 18, 1913.)

A. This map shows Lake Ontario with the lower end of Niagara River and the upper end of the St. Lawrence River. The depths on this chart are in fathoms in the white, in feet in the blue.

Q. Are there any canals shown on that chart?

A. It also shows the Welland Canal, or a portion of it, that is all. It does not reach down far eough to catch the St. Lawrence Canal.

Q. Do you know what the character of freight is that is carried on that lake?

A. Mainly package freight.

Q. And from points—

A. From port to port.

Q. From port to port on the lake?

A. On the lake.

Q. I show you a chart here entitled "Chart No. 6, St. Lawrence River"; I ask that it be marked Williams' Exhibit 15. Will you indicate what that chart shows in a general way?

(Chart shown witness marked Williams' Exhibit 15, March 18, 1913.)

A. That chart shows the upper end of the St. Lawrence River, or what might almost be called the lower end of Lake Ontario, although it is really a part of the river. It represents a portion of the famous Thousand Islands. The soundings on this chart are in feet, both in the white and the the blue.

Q. As they are indicated by figures?

A. As indicated by figures. This does not reach yet to the head of the canal system.

Q. I show you another chart here which is entitled "Chart 5, St. Lawrence River," to be marked Williams' Exhibit 16. What does that chart show in a general way, Mr. Williams?

(Chart shown witness marked Williams' Exhibit 16, March 18, 1913.)

A. This chart shows a section of the St. Lawrence River from a point above Alexandria Bay down to Chippewa Point. This is still in the navigable portion of the river.

Q. At all points?

A. At all points.

The depths are given in feet both in the white and in the blue.

Q. I show you another chart here entitled "Chart 4 St. Lawrence River," which I ask to be marked Williams' Exhibit 17. What does this chart show?

(Chart shown witness marked Williams' Exhibit 17, March 18, 1913.)

A. This shows a portion of the St. Lawrence extending from Chippewa Point to about four miles below Brockville. The depths are indicated in feet both in the white and in the blue.

Q. I show you another chart here which is entitled "Chart 3, St. Lawrence River," to be marked Williams' Exhibit 18. State in a general way what this chart shows.

(Chart shown witness marked Williams' Exhibit 18, March 18, 1913.)

A. This chart shows a portion of the St. Lawrence River from a point about eight miles above Ogdensburg to a point about a mile below the Galop Island. We now come to that portion of the St. Lawrence River which is only half navigable. That is, boats may travel it in one direction but not in the

other. And we then get into the artificial channels along the Canadian side of the river which permits the return of boats which have passed down through the main stream.

Q. What channel is that, it is called the Northern Channel, is it?

A. The name is not on it here. It is the north channel, but that is not the canal. There are no locks there.

Q. How far is Ogdensburg from Lake Ontario, the foot of Lake Ontario in a general way?

A. About 67 miles.

Q. Is there any gaging section on the St. Lawrence River at or near Ogdensburg?

A. About 15 miles below at point Three Points which is not shown on this chart, there is a gaging section.

Q. Can you indicate about where that is?

A. Well, it will be on the next chart.

Q. Is there any gaging point—is there an Oswego gage?

A. Oswego gage is out in Lake Ontario, but the gage at Ogdensburg was used as the reference gage in the gaging of the St. Lawrence River.

Q. I show you chart marked "Chart 2, St. Lawrence River," which may be marked Williams' Exhibit 19 of this date. Will you describe that in a general way?

(Chart shown witness marked Williams' Exhibit 19, March 18, 1913.)

A. This shows the St. Lawrence River from the head of the Galop Canal down to Weaver's Point.

Q. Was there a gage section on the St. Lawrence River? Can you indicate where that was on this map?

A. That was in the vicinity of point Three Points, which is about a mile and a half below the Village of Iroquois on the Canadian side. That is one of them.

Q. I show you another chart here entitled "Chart 1, St. Lawrence River," which may be marked Williams' Exhibit 20 of this date. Will you describe that in a general way?

(Chart shown witness marked Williams' Exhibit 20, March 18, 1913.)

A. This shows the St. Lawrence River from Weaver's Point to St. Regis Island, and includes the Farron Point Canal, the Cornwall Canal, and gets us to the upper end of Lake St. Francis.

Q. Have the channels of the St. Mary's River, and the St. Clair and Detroit Rivers, been improved at any time by the United States Government?

A. Yes. These improvements have extended over a period

beginning back in the fifties, to date, and work is going on now, or was until the winter interfered with it.

Q. What was the original depth of the water in the St. Clair and Detroit Rivers before the improvements were commenced?

A. The original depths of the St. Clair and Detroit Rivers at the controlling points was about eight feet on St. Clair Flats; that is the foot of the St. Clair River, and about the same at the Lime Kiln Crossing or Ballard's Reef in the Detroit River. I mean by "controlling points" the points which regulated the depths or draft of boats that could pass up or down the river, passing through the system. That was the shallowest place in the river; those are the controlling points.

Q. In other words the shallowest place in the St. Clair River was at the St. Clair Flats, at the head of Lake St. Clair?

A. Lake St. Clair.

Q. At that time?

A. Yes.

Q. Then the controlling point or the shallowest place in the Detroit River, was at the Lime Kiln Crossing and Ballard's Reef?

A. Yes, in the region through the Lime Kiln.

Q. When was the first improvement made at those points if you remember?

A. The St. Clair Flats Canal was constructed about the time of the Civil War, or before; completed in 1858, giving a depth of 12 feet. Then between 1857 and 1871 it was deepened to 13 feet, and following that improvements were made both at the St. Clair Flats and the Lime Kiln, deepening the water to 16 feet. These improvements were practically completed in 1876.

Q. Then what was the next improvement made in the depth?

A. The next improvement was the removal of the bar at the mouth of Black River, at Port Huron.

Q. At what time was that?

A. Which was where the work was carried on between 1874 and 1879; and in 1876 the further improvement of the Lime Kiln Channel designed to give a depth of 20 feet of water was begun, which improvement was completed in 1891.

The 1876 enlargement contemplated a widening of the channel as well as deepening, and the work seems to have been carried on in a more or less desultory sort of way at first.

Q. In a general way, what proportion of the improvements have been made subsequently to 1890 and before, in those two rivers, the St. Clair and Detroit?

A. Well, something more than 20 times as much material

has been removed from the Detroit and St. Clair Rivers since 1890 as had been removed up to that time.

Mr. Wilkerson: What do you mean by "removed"?

A. Removed from its original place.

Q. And put in some other place in the river?

A. Put some place else; may have been put in the lake or the river.

Q. You mean the total quantity moved?

A. I mean the total quantity moved.

Q. Without regard to where it was put?

A. Without regard to where it was put.

Mr. Wilkerson: You have the figures on how much went back in the river at some other point?

Mr. Adcock: And how much washed out; yes, we have an exhibit on that which will show exactly.

Adjourned to 10:30 a. m. March 19, 1913.

March 19, 1913—10:30 a. m.

GARDNER S. WILLIAMS resumed the stand, testified further as follows:

Mr. Adcock: When was the United States Lake Survey established, Mr. Williams?

A. Well, the old original United States Lake Survey dates from somewhere in the 'fifties, I believe, and its work was substantially completed somewhere around the late 'seventies or 1880. The Lake Survey office was revived, I believe, about in the 'nineties. There was a period of a year or two, I think, when there was no work done under the Lake Survey, so-called; but the work of the Lake Survey was taken up again and appears prominently in the reports of the Chief of Engineers for the year 1900.

Q. What has been the scope of their work, briefly?

A. Primarily the purpose of the Lake Survey—

Q. I mean in the later years.

A. The same statement covers both. Primarily the purpose of the Lake Survey was to provide adequate information as to the channels, possibilities of navigation on the Great Lakes and their connecting waters; and the scope of this was extended to involve or include measurements of the outflow of the Great Lakes and the recording or the collection of observations of the elevations of water in the Great Lakes at various points. So that at the present time the scope of the Lake Sur-

vey work embraces practically everything in the way of hydrography of the Great Lakes; that is, the preparation of charts for navigators and charts for general information as to the depths and areas and contours of the Great Lakes, and also in regard to meteorological conditions, the discharge, and the rise and fall of the lakes and their connecting waters.

Q. The term "hydrography of the Great Lakes" has been used by you, also the word "hydraulics." Will you define those two, with reference to the Great Lakes?

A. The term hydrography is of kindred derivation to the word geography with which we are all familiar; geography being the depicting of the characteristics of the earth or of the land, and hydrography being the depicting of the characteristics of the water. Hydrography has been extended to include also questions of measurements of water flowing and so on, though originally the word was intended to cover simply the mapping of the conditions, or the representation of the conditions, examination into such conditions as would be shown upon a map, or described in some such way.

The term hydraulics is used to designate that branch of physical science which has to deal with the stability, equilibrium and motion of fluid bodies. As we apply it in this case, we confine it to the laws of the motion and equilibrium of water, leaving out the lighter fluids.

Q. What was the scope of the work of the International Waterways Commission, and the Board of Engineers on Deep Waterways?

A. The scope of the Board of Engineers on Deep Waterways was to investigate and report upon a plan for a deep waterway to connect the Great Lakes with the Atlantic Ocean. That report was made in furtherance of the earlier report of the so-called Deep Waterways Commission, which pointed out the possibilities of such a connection and the advantages which might accrue from it.

In connection with that work they also investigated and reported upon the feasibility of regulating the levels of the Great Lakes for the maintenance of deeper channels therein, by means particularly of a regulating dam or weir to be placed near or at the foot of Lake Erie.

The International Waterways Commission was appointed to further investigate the question of the regulation of the lakes, with particular reference to the international complications which might be involved, and among their instructions was that if they should find it advisable to regulate the levels of the lakes thereby involving international action, that

they should present a draft of a treaty to cover the points which would have to be adjusted between the United States and Canada.

The Commission had also various other matters appertaining to boundary waters referred to it, and was delayed for some time in taking up the matter of the regulation of Lake Erie; but in 1910 they published a report upon that subject which contains the computed discharges of all the outlets of the Great Lakes, and tabulated discharges of the St. Mary's, Detroit, Niagara and St. Lawrence Rivers. These discharges are based upon the observations for discharge which have been made under the direction or by the Lake Survey office and upon the records of lake elevations as recorded in that office. The assumptions and computations of discharge were, however, made entirely independent of the Lake Survey office, and are an independent deduction from the data obtained by the Lake Survey office. That report is known as the report upon the regulation of Lake Erie, report of the International Waterways Commission upon the regulation of Lake Erie, and is dated 1910.

Since the finishing of that report the Commission has been engaged in the demarcation of the international boundary line through the lakes, and upon some further studies upon the possibility of raising the level of Lake Erie by the construction of a dam elsewhere than at the foot of Lake Erie.

Q. You spoke of the regulation of Lake Erie. Will you state just what that work contemplated, its effect and so forth?

A. The original contemplation, which is due to a suggestion of the late Mr. George Y. Wisner, who was a member of the Board of Engineers on Deep Waterways, was to construct at the foot of Lake Erie a submerged dam, and a series of sluice gates, so that when Lake Erie was at a high stage the gates might be opened.

Mr. Wilkerson: Is this contained in some proceeding of the Commission?

Mr. Adcock: No, he is simply describing the regulation works as they were contemplated.

The Witness: So that when Lake Erie was high, or reached near the high water mark, the gates could be opened and additional water discharged, while as Lake Erie fell the gates would be closed, and with the obstruction which was provided by the submerged dam, the lake would be prevented from falling to its low water plane. This of course would maintain the lake at a more constant elevation, and at a

higher elevation than it has occupied on the average under the present conditions.

It was contemplated to regulate the surface of Lake Erie within average range of about two feet, if I remember correctly, and at a plane somewhat higher than the present low water plane; I think about two feet higher. The raising of the water of Lake Erie would reduce the fall in the Detroit River, thereby decreasing its discharge and raising Lake St. Clair, which in turn would decrease the fall in the St. Clair River and thereby raise Lake Huron, the effects being probably about one-half as much in St. Clair and about one-fourth as much in Lake Huron.

Mr. Wilkerson: Is this your conclusion or that of some one else?

A. It is mine; coincides with the Board's practically.

Mr. Adcock: When were discharge measurements made by the United States Lake Survey of the St. Clair River?

A. The earliest ones were made in the 'sixties, but they may be neglected, as the means by which they were made were so crude and the methods pursued were so inaccurate that although for many years they were the best we had and the only ones we had, they are to be entirely superseded by the results obtained from the later, more precise determinations or work of the Lake Survey, which began with the measurements of the St. Clair in 1899 and continued through 1902, and was taken up again in 1908 and continued through 1909 and 1910.

Q. How many discharge measurements were made, if you remember, in 1909 and 1902?

A. I don't think I can recall and I do not have the memoranda at hand. That has, however been testified to by the complainant's witnesses.

Q. For what period during each year did they cover?

A. In the main they covered the open season of navigation, although some measurements were made during the winter.

Q. That is on the St. Clair River?

A. On the St. Clair River.

Q. Where were those measurements made?

A. Those measurements were made at what is known or designated as the Section Dry Dock on the St. Clair River about five miles below the foot of Lake Huron.

Q. Can you designate on the map or chart entitled "St. Clair River," Williams' Exhibit 7, where that measurement was made?

A. Well, it was made in the vicinity of the legend "Reid

Wrecking Company Dry Dock Abandoned," which is found printed across the St. Clair River.

Q. Were there measurements made at any other place in the river during that period?

A. There were measurements made during the winter at a point further up stream, in fact within I think about a mile or less of the foot of Lake Huron.

Q. Do you remember what winter that was?

A. That was in the winter of 1900 and 1901, I believe.

Q. Were those measurements made at the same time that the measurements were made at the Dry Dock Section?

A. No, they were not simultaneous. There were measurements made at the Dry Dock Section during that winter, and then the party went from the Dry Dock Section to this upper section, and later returned to the Dry Dock.

Q. Were there any measurements made in the St. Clair River at the same time measurements were made in the Dry Dock Section?

A. No, there were no simultaneous measurements at two stations in the St. Clair River, so far as I have been able to discover.

Q. Was there a Gorge Section there, what they call the "Gorge Section"?

A. There is a section which has later been designated as the Gorge Section, which is about the narrowest section of the river and is about half a mile below the foot of the lake. Measurements were made at this section in 1908, 1909 and 1910, but no measurements were made there during the earlier period of gages.

Q. Were there any measurements made on the Niagara River?

A. (No answer.)

Mr. Wilkerson: These later measurements you have referred to were not before the International Waterways Commission, were they?

A. No, unless it is possible that the 1908 measurements may have been used.

Mr. Adcock: That is by the International?

A. By the International Waterways Commission. I don't know that they were, and I think it probable that they were not, but it is possible that they might have been.

Q. Were any measurements made of the discharge of the Niagara River by the United States Survey?

A. Yes, there were measurements made at the Niagara River by the United States Lake Survey at the request, first,

of the Board of Engineers on Deep Waterways, and subsequently additional measurements were made by the Lake Survey itself. Prior to these measurements, there had been some others made either by the Lake Survey or by the U. S. Engineer office at Buffalo, which appear to have been made in the early 'nineties. The reliable measurements, or the most reliable measurements of discharge of the Niagara River are, however, those made since 1899.

Q. Were they made during the period from 1899 to 1902, the measurements on the Niagara?

A. They began in September, 1898, and continued into 1900.

Q. Where were those measurements made, referring to Williams' Exhibit 12 entitled "Chart Buffalo Harbor"?

A. Those measurements were made from the International Bridge, so-called, which is about 2½ or 3 miles, say 3 miles, below the foot of Lake Erie, and also at another section in that vicinity about 2,000 feet further down stream.

Q. That was called what?

A. That was called the "Open Section", the former being designated as the "Bridge Section" in the records.

Q. They are designated on the map here, the first one is mentioned as International Bridge.

A. International Bridge; the location of the second one is near the foot of Squaw Island.

Q. Will you state how discharge measurements are made by the use of the current meter?

A. The process of measuring discharge by means of the current meter is, first, to make a measurement of a section, a cross-section of the stream to determine the area of the wetted portion, or the area of the body of water passing the point in question.

Points are then selected at intervals across the stream at which measurements are taken with the current meter, by lowering it from the surface to the bottom and occupying various positions as it passes down for a sufficient length of time to enable the meter to take up and repeat the velocity of the current. The number of points that are observed in a vertical, of course depends upon the degree of precision with which it is desired to get the changes of velocity from point to point. But common practice has been to make use of an observation at every tenth of the depth. The average velocity indicated by the meters at the several positions, when adjusted for difference of distance between successive positions,

if there be any, is taken as the mean velocity for that vertical, and a second or another vertical is observed in the same way.

In this way a series of readings of the velocity of the current is obtained at numerous points throughout the cross section, generally arranged in a series of vertical columns. The mean velocity of the vertical, when multiplied by the sum of half the areas between that vertical and the one next to it on either side is assumed to represent the velocity through that portion of the stream; or the mean velocities of the verticals may be plotted and a curve drawn through the observations indicating the total velocity which, when the mean ordinate of the area enclosed between this curve and the base is measured, gives the mean velocity of the water; and this in turn, when multiplied by the area of the cross section would give the discharge. For rapid gauging, it is customary after having examined the distribution of velocities through the vertical to select certain points which are called "index points" which bear a fixed relation to the average velocity of the vertical, so that in making a gauging of the stream, after the preliminary work has been done, it is only necessary to occupy one or two points in a vertical in order to get a measurement, instead of having to occupy all ten or more, as the case might be. In that case the measurement of the discharge of the river comprises the occupying of one or more points on each vertical across the stream, or if conditions warranted it, the number of verticals might be reduced, and certain controlling ones simply observed.

Q. Is it more difficult to measure the discharge of a large river than a small river?

A. Very much.

Q. Why is that?

A. Principally because of the difficulty of knowing what the condition of your measuring apparatus is. In a large river it is impossible to see it. In a small stream you can generally see the instrument and know in which way it is pointing, and whether there is any obstruction upon it, and what its condition is generally; whereas in a deep stream it is out of sight, and you can only judge by the information that is clicked to you through the telephone.

Q. Would that be true of a stream of the depth of the St. Clair River for instance, and Niagara?

A. Oh, yes, certainly.

Q. St. Lawrence?

A. There is a further difficulty in measuring in the deep stream as compared with a shallow one that whereas in the latter it is possible to hold the meter rigidly at a position by means of a rod, so that its position is exactly known, in the deep stream the meter has to be suspended upon a cord or cable or wire, and it then becomes a matter of some uncertainty as to just where the meter is, and in what direction it is pointing.

Mr. Wilkerson: I just wish to suggest that you have him define a little more definitely what you mean by the term "difficult", whether you mean difficult in the way of making the observation, or the possibility of a precise result after the difficulties are overcome?

Mr. Adcock: I will get to that in time.

Mr. Austrian: Just let him explain what he means by "difficult". You say "difficulty in measuring"? What do you mean by that?

A. I use that as applied to the difficulty of obtaining precise results. It also applies to the mechanical difficulties, the physical difficulties. It is very much easier to measure a small stream than it is a large one.

Mr. Adcock: Do you know how wide the St. Clair River is or was, at the time these gaugings were made at the Dry Dock Section and the Gorge Section?

A. The Dry Dock Section was somewhere in the neighborhood of 2500 feet, and the Gorge Section I think was about 1800 feet.

Q. How far apart were the verticals?

A. I think originally every 100 feet.

Q. In a river of the velocity of the St. Clair River, how often would the electric current make a break to indicate the revolutions of the current meter?

A. That would depend altogether on the type of meter used, and its rating. The revolutions per second will probably be about 2/3 of the velocity per second with the type of meters that were used, so that with a velocity of three feet a second, you would have about two revolutions per second or 120 a minute. And there would be a break at each revolution.

Q. And the way those 120 revolutions would be counted, would be by the ear, as we hear, the same way a doctor counts the pulse?

A. Yes. They do have recording devices, which record on a recording mechanism.

Mr. Wilkerson: How about the Lake Survey?

A. I think the Lake Survey has used the recording devices almost entirely, so that the counting is done mechanically.

Mr. Adcock: You mean it may be done mechanically?

A. It may be done mechanically and that was the practice.

Q. In the Lake Survey?

A. In the Lake Survey.

Q. Is the accuracy with which the current meter determines or records the velocity dependent in any way upon the rating of the meter?

A. Entirely. That is, that is the only means we have of knowing the number of revolutions of the meter wheel, which corresponds to any velocity.

Q. In a large river like the St. Clair, does the velocity change from time to time?

A. It does, very rapidly.

Q. Is the velocity in different portions of the river different?

A. It is.

Q. That is at different depths?

A. Both at different depths and at different points across the river.

Q. So the velocity at one-tenth depth or two-tenths depth to one vertical might change in how short a time if at all?

A. Why it would change somewhat in a few seconds. That is, it is vibrating, pulsating all the time.

Q. Would the current meter wheel be running continuously at a certain rate, or would there be pulsation or changes?

A. According to my own observation I never have found a current meter wheel to run regular in flowing water. There is always pulsation present.

Mr. Wilkerson: You are speaking now of two kinds of changes of velocity, one at a given point?

A. Yes.

Q. At the cross section; and the other as between the various points in the same cross section?

A. Yes, and my last statement refers to the changes at a certain point.

Mr. Wilkerson: At a certain point in the cross section. That is the one with reference to which he uses the term "pulsation"?

The Witness: Yes.

Mr. Adcock: Have you been present at the taking of the testimony of the complainant?

A. I was present at the taking of the testimony of all the witnesses of the complainant except Colonel Townsend and Mr. Coulby, and one day of Mr. Wheeler.

Q. You have read the testimony, have you not?

A. I have read the testimony of all the witnesses, and reread that of several.

Mr. Adcock: These documents (referring to same) are the ones that were offered in evidence.

Mr. Wilkerson: If you have any papers that have been obtained from the Government records that you want to use, you may have them marked, offer them and use them in any way you please, for the purpose of this examination, providing that we reserve the right to check up on them and verify them to determine if they are inaccurate in any way, or if we conceive they are not complete to add to them such other portions of the record as we claim are essential to make them complete.

Mr. Adcock: There are certain records or measurements which offered, in evidence, by the complainant.

The Witness: No, they were not offered in evidence; they were identified at the request of the defendant.

Mr. Adcock: They were identified and they were the basis of those exhibits of yours, weren't they?

Mr. Wilkerson: There are some measurements which were produced by the Government in connection with the examination of the Government's expert witnesses. They were identified as the figures and tables upon which the computations of the Government's witnesses were based, and they were produced for inspection of the experts and counsel for the defendant, at their request. And they are here in this case to be used by both sides for whatever purposes they may be legitimately used in this case. They are not formally offered and they may be treated—

Mr. Adcock: As though they were in evidence?

Mr. Wilkerson: As if in evidence, at the hearing.

Mr. Adcock: They are in evidence now, and so that they may be identified, I will ask that the Commissioner mark them.

The Witness: They have been marked once.

Mr. Wilkerson: Are those all the tables we produced?

Mr. Adcock: I think so.

Mr. Wilkerson: Are you using all that we did produce?

A. Yes.

Q. And in addition to that you are using some other which you have since obtained?

A. In addition to that I am using some others I have since obtained.

Q. From the same source?

A. From the same source.

Q. As the ones which you produced?

A. (No response.)

Mr. Adcock: Referring to the records of measurements which Mr. Wilkerson has spoken about, I have here a paper entitled "United States Lake Survey, Discharge Measurements Dry Dock Section St. Clair River 1899 to 1900 to 1902"; also record of discharge measurements made in 1908, consisting of seven sheets, which will be marked Williams' Exhibit 21.

(Whereupon documents above referred to were marked by the Commissioner Williams' Exhibit 21.)

Mr. Adcock: This was identified by complainant's witness, Shenehon, in File 6, page 14, being page 472 of the continuously paged record.

I now submit to the Commissioner for identification (of the series of tabulations above referred to) seven sheets of tabulations, the first sheet being entitled "United States Lake Survey, Hydraulics of St. Clair River, mean slope for period November to December, 1908"; the second sheet being entitled "United States Lake Survey, Hydraulics of St. Clair River; Summary of Discharge Measurements Section Gorge, Sherman Moore, Junior, Engineer, April, 1909"; the third sheet being entitled "Hydraulics of St. Clair River, Summary of Discharge Measurements Section Dry Dock, Sherman Moore, Junior, Engineer, April 1909"; the fourth page being entitled "United States Lake Survey. Hydraulics of St. Clair River, Discharge of St. Clair River Section Gorge, Sherman Moore, Junior, Engineer, March, 1910"; the fifth sheet being entitled "United States Lake Survey. Hydraulics of St. Clair River; Discharge of St. Clair River Section Gorge, Sherman Moore, Junior, Engineer, March, 1910"; the sixth sheet being entitled "United States Lake Survey, Hydraulics of St. Clair River, Discharge of St. Clair River Section Dry Dock, Sherman Moore, Junior, Engineer, March, 1910;" and ask that all these be marked Williams' Exhibit 22, being a series of tabulations not heretofore identified in this case, but furnished by the United States Lake Survey.

(Tabulations above referred to were marked by the Commissioner Williams' Exhibit 22.)

Mr. Adcock: I hand to the Commissioner for identification a file of blue prints furnished by the Lake Survey office, each of which is marked "U. S. Lake Survey", and being tables comprising 37 sheets, the same being blue prints accompanying the report of Junior Engineer W. T. Richmond, on the hydraulics of the St. Clair River under date of April, 1911, not heretofore identified. To be marked Williams' Exhibit 23.

(The 37 sheets above referred to were marked by the Commissioner Williams' Exhibit 23.)

Mr. Adcock: I now submit to the Commissioner for identification a series of five sheets of records of discharge measurements entitled "Summary of Discharge Measurements International Bridge Section and Open Section of the Niagara River for the years 1898, 1899 and 1900", each sheet being identified by the signature of F. C. Shenehon, United States Assistant Engineer 1906. These sheets have been identified by complainant's witness Shenehon, and are of the series referred to by Mr. Wilkerson. I ask that they be marked Williams' Exhibit 24.

(The five sheets above referred to were marked by the Commissioner Williams' Exhibit 24.)

Mr. Adcock: I submit to the Commissioner for identification two sheets containing records of discharge measurements of the St. Lawrence River, each sheet being entitled "Summary of Discharges, Three Points Section," covering the discharge measurements in 1900 and 1901; the sheets being also identified by the signature of F. C. Shenehon, Assistant Engineer, May, 1906. These were identified by complaintant's witness Shenehon. I ask that they be marked Williams' Exhibit 25.

(The two sheets above referred to were marked by the Commissioner Williams' Exhibit 25.)

Mr. Adcock: I submit to the Commissioner for identification a group of six tables or six sheets of elevations of the Great Lakes as follows: Superior, at Superior, Wisconsin, and Marquette, Michigan; Michigan, at Milwaukee, Wisconsin; Huron at Harbor Beach, Michigan; St. Clair at St. Clair Flats Canal; Erie at Cleveland, Ohio; Ontario at Oswego, New York; being duplicates of Exhibits D, E, F, G, H and I for identification, identified by complainant's witness Shenehon, the same being extended from 1908 through 1912, fur-

nished by the office of the United States Lake Survey. The original of 1908 was identified by witness Shenehon. I ask that these be marked Williams' Exhibit 26.

(The six sheets above referred to were marked by the Commissioner Williams' Exhibit 26.)

Mr. Adcock: I now submit to the Commissioner for identification two sheets of tables furnished by the United States Lake Survey, one giving the mean monthly elevation of the Detroit River at Amherstburg, Ontario, and of Lake St. Clair at Windmill Point; and the second giving the mean monthly elevation of the Detroit River at Fort Wayne. These have not been heretofore identified. To be marked Williams' Exhibit 27.

(The two sheets above referred to were marked by the Commissioner Williams' Exhibit 27.)

Mr. Adcock: I now submit to the Commissioner for identification tables of mean daily elevations of water surface of Lakes St. Clair and Huron for selected periods, such tables having been furnished in conformity to a request of the United States District Attorney by the United States Lake Survey, and not heretofore identified. To be marked Williams' Exhibit 28.

(Tables above referred to were marked by the Commissioner Williams' Exhibit 28.)

Mr. Adcock: I now submit to the Commissioner for identification a series of tables embracing 17 typewritten pages and one blue print of daily mean gauge elevations for Lake Erie at various points for selected periods, furnished in conformity with the request of the United States District Attorney by the United States Lake Survey, and the United States engineer offices on Lake Erie. To be marked Williams' Exhibit 29.

(Tables above referred to were marked by the Commissioner Williams' Exhibit 29.)

Mr. Adcock: I now submit to the Commissioner for identification a series of tables consisting of five typewritten sheets representing the mean monthly elevations of Lake Ontario, Lake Erie and Lake Huron, and mean daily observations of Lake Ontario at Oswego and Ogdensburg for selected periods. These were furnished in response to a request of the United States District Attorney by the United States Lake Survey. To be marked Williams' Exhibit 30.

(Five typewritten sheets above referred to were marked by the Commissioner Williams' Exhibit 30.)

Mr. Adcock: I now submit to the Commissioner for identification a series of two sheets showing the mean monthly and annual rainfall in inches on the drainage areas of the Great Lakes, for a series of years terminating with 1906, having been furnished in response to a request of the United States District Attorney by the United States Lake Survey and not heretofore identified. To be marked Williams' Exhibit 31.

(The two sheets above referred to were marked by the Commissioner Williams' Exhibit 31.)

Mr. Adcock: I now submit to the Commissioner for identification pages 2855 to 2883, being appendix FFF2 of the annual report of the Chief of Engineers for 1903, with charts and tables, being the report upon the outflow rainfall and evaporation of the Valley of the Great Lakes, prepared by complainant's witness Wheeler and identified and referred to by him in his testimony in this case. To be marked Williams' Exhibit 32.

(Pages of Appendix FFF2 above referred to were marked by the Commissioner Williams' Exhibit 32.)

Mr. Adcock: I now submit to the Commissioner for identification pages 90, 91 and 92 of the water levels of Lake St. Clair, to be marked Exhibits 33 A, B and C respectively; page 94, the water levels of Lake Erie at Buffalo breakwater to be marked Exhibits 33D; page 95, water levels of Lake Ontario at Charlotte, to be marked Exhibit 33E; page 101 of the discharge from Lake Superior to be marked Exhibit 33F; page 102 on the discharge from Lake Huron-Michigan to be marked 33G; page 103 of the discharge from Lake Erie from the Report of the International Waterways Commission on regulation of Lake Erie under date of 1910 to be marked 33H; page 104, discharge from Lake Ontario to be marked Exhibit 33I.

(The pages above referred to were marked by the Commissioner as already indicated.)

Recess to 1:30 P. M.

After recess—1:30 P. M.

GARDNER S. WILLIAMS, resumed the stand, and testified further as follows:

Mr. Adcock: Since the institution of this suit, Mr. Williams, have you made any further study than you have mentioned heretofore with reference to the hydraulics and hydrography of the Great Lakes?

A. I have made a very careful study of the evidence presented by the complainant, and of tables of reduced data, which have been furnished to me through the courtesy of the complainant, being derived from the original sources upon which complainant's testimony in regard to the discharge and effects upon lake elevations is based.

Q. Have you made any particular studies and deductions from the records of discharge measurements made on the St. Clair River, the Niagara River and the St. Lawrence River, which have been referred to?

A. I have.

Q. I show you here Williams' Exhibit 21 referring to discharge measurements Dry Dock Section St. Clair for certain years, and ask you to state in a general way what is shown by that exhibit?

A. This exhibit shows the record for the several gaugings of the St. Clair River between 1899 and 1908, exclusive of those made during the ice season and indicates the consecutive number of the measurement, the date of the measurement, the elevation of the water surface of Lake Huron at the time of the measurement, the elevation of the water surface at St. Clair Flats at the time of the measurement, the fall from Lake Huron to St. Clair Flats at the time of the measurement, the direction and velocity of the wind at the time of the measurement, and the discharge; and also arranged in groups of ten observations at similar stages, the stages being based upon the elevation of Lake Huron, the mean elevation of Lake Huron for the several observations in each group, the mean elevation of St. Clair Flats, the mean fall from Lake Huron to St. Clair Flats, and the mean discharge in cubic feet per second.

Mr. Shenehon: How many in each group?

The Witness: I said there were 10 in general. There are 10 in all groups of the observations for 1899, 1900 and 1902; and these groups are indicated by the letters from *A* to *U*

inclusive, there being 10 in all groups from *A* to *T* inclusive, and four observations in group *U*. These groups are also indicated by number, from 1 to 21, group 21 being that having but four observations. In the observations for 1901 there are four groups, Groups 1, 2 and 3, which are also designated as *V*, *W* and *X*, containing 10 observations each and Group 4, which is designated also as *Y* contains six observations

In the observations for 1908 there are two groups, one designated Group 1 or *Z*, which contains seven observations, and one designated Group 2 or Alpha, which contains eight observations.

Q. The elevation of Lake Huron is referred to there. Do you know at what point the gauging was made?

A. The elevation of Lake Huron referred to is understood by me from the testimony of the complainant to be at Harbor Beach. It has been my understanding that it is Harbor Beach.

Q. Do you know how the elevation indicated there, the Harbor Beach gauge, was derived?

A. It was not observed simultaneously with the discharge measurements in all cases. It might have been in some. Where it was not observed, it was derived from a gauge relation, first, between the gauge at the Grand Trunk Railroad Dock and Fort Gratiot, and then by a relation from Port Gratiot to Harbor Beach.

Q. Will you indicate on Williams Exhibit 7, Discharge of St. Clair River, where the Grand Trunk gauge is located, and the Fort Gratiot gauge?

A. (Referring to Exhibit 7) The Grand Trunk gauge is located within a mile of the foot of Lake Huron; I think a little less than a mile. The Fort Gratiot gauge is practically at the foot of Lake Huron, and is indicated on this chart by the legend "Fort Gratiot Light and Fog Whistle". The Harbor Beach gauge is some 60 miles I think up Lake Huron.

Q. Do you know when the Grand Trunk Gauge was read with reference to the time when the observation was made?

A. It was read I believe simultaneously—or continuously during the periods of observation, at frequent intervals, and through part of the observations I think a self-registering gauge was used there.

Q. When you speak of getting the Harbor Beach gauge from the relation between that and Fort Gratiot and Grand Trunk, just state how that was done.

A. Simultaneous observations of the water stage are

taken at two of the gauges in question, and by the relation thereby established from one to the other, the reading of one gauge or the mean reading of one gauge corresponding to the mean reading of the other is established, and that correction is then applied to the readings of one to get the reading of the other.

Of course it may be found that there is no mean correction, but that there is a change depending upon the change of elevation of the lake surfaces, in which case where the law of the change can be established, the corrections are made in accordance with that law; the difference possibly being greater for high elevations than it is for low ones.

Q. Do you know how long a time it took to make one gauging on the river at the Dry Dock Section, say?

A. As I remember the complainant's testimony it was about three hours.

Q. Have you made any study of the records of the observations in the three rivers which I have mentioned, or have you made any calculations to determine the accuracy or inaccacuracy of the observations and the results reached by the complainant?

A. I have so far as it has seemed to be possible from the information that has been at my disposal.

Q. Have you made any examination of the records of the observations, measurements and with reference to lake stage and so forth?

A. I have.

Q. I will ask you in a general way if the records of the measurements, discharge measurements of the Niagara and St. Lawrence Rivers are arranged in substantially the same manner as the records of the discharge measurements of the St. Clair?

A. They contain the similar information as to lake stage or lake elevation and discharge, wind. Of course in these observations there is no question of a gauge below the station, that is of another lake being involved other than the one at the head. Nevertheless the elevations of the lake, and of the gauge at the gauging section are given in these tabulations, and the observations are not grouped as the observations on the St. Clair, but this tabulation simply shows them in chronological order on the St. Lawrence and on the Niagara River, both.

Q. Based upon the records of these discharge measurements that have just been referred to, and upon the facts

which have been stated by the complainant's witnesses, have you reached any conclusions, or do you find any indications which would tend to determine the accuracy or inaccuracy of the observations made and the results reached by the complainant from such observations?

A. I do.

Q. I show you, Mr. Williams, certain tables, being marked 1 to 54 inclusive, and plates from 1 to 8 inclusive following in numerical order, and ask you to state what they are? They may be marked Exhibit 34, being Tables 1 to 54 and Plates 1 to 8, and I will ask you to state what that exhibit contains.

(The documents above referred to were marked by the Commissioner Williams' Exhibit 34.)

A. That exhibit embraces the computations or the reduced computations which I have made in determining the hydraulic questions which seem to me to be involved in this case.

Tables 1 to 17 inclusive deal with the examination of the precision of the Complainant's observations. Tables 18, 19, and 21 present the elevations of the water surfaces of the Great Lakes, Huron, St. Clair and Erie, and the falls between them and the relation of the fluctuations or changes of annual elevation of these lakes.

Tables 22 to 39 deal with the derivation of the increments of the St. Clair River.

Table 40 is a computation of the discharge of the St. Clair River from 1900 to 1907 by the use of the equations or the equation derived from the preceding tables.

Tables 41 to 43 deal with the increment and the discharge of the St. Lawrence River.

Table 44 deals with the fluctuation or annual change of stage of Lakes Erie and Ontario.

Tables 45 to 47 deal with the increment of the Niagara River.

Table 48 presents an estimated rainfall upon the drainage areas of the several lakes, based upon the rainfall records for Lake Superior at Marquette, for Lakes Michigan-Huron at Milwaukee and Detroit; for Erie and St. Clair at Detroit, Cleveland and Buffalo, for Ontario at Buffalo, Oswego, Rochester and Toronto.

Tables 49 and 50 present the average annual elevation of Lake Ontario and of Lake Superior; and Table 51 is a summary of the annual elevations and differences of elevation from lake to lake of Lakes Superior, Michigan-Huron, St. Clair, Erie and Ontario.

Table 52 is a further summary of similar information.

Table 53 represents the amount of material that has been dredged from the channels of the St. Clair River, from Lake St. Clair and the Detroit River, from 1870 to 1910, inclusive.

Table 54 presents the relative change of annual stage of Lakes Erie and St. Clair.

Plate 1 is a reproduction as accurately as it was possible to reproduce it by the services of an accurate draftsman of Complainant's Exhibit 1; the purpose of the reproduction being to get it to a size which would be convenient for reference in connection with the other data presented in these tables.

Plate 2 is a similar reproduction of Complainant's Exhibit 2. Plate 3 is a similar reproduction of Complainant's Exhibit 3. Plate 4 is a similar reproduction of Complainant's Exhibit 4.

Plate 5 is a representation of the increment for the St. Clair River as derived by the methods indicated in the reductions made by myself.

Plate 6 is a similar representation of the increment of the St. Lawrence, as similarly derived.

Plate 7 is a photographic reproduction of a portion of the chart of the head of the St. Clair River, said chart being one obtained by me from the United States Lake Survey office about 1897, which is stamped with the legend "Aids to Navigation corrected from information received to April 20th, 1892." To this chart has been added by me two parallel lines at the head of the river enclosing Fort Gratiot.

Plate 8 is from a chart of the same river, a duplicate of the one placed in evidence as Williams' Exhibit 7, which was obtained from the United States Lake Survey office in February, 1913, and by its stamp purports to be corrected to "December 26th, 1912."

On this chart there has also been drawn two parallel lines enclosing Fort Gratiot, which I believe to be in a position corresponding to those drawn on Plate 7.

Q. From what data and information were these tables compiled?

A. With the exception of Table 48 of precipitation, Table 53 on dredging, they have all been derived from the original tables furnished by the complainant through the office of the United States Lake Survey, or from one or two of the other United States engineers' offices along the Great Lakes, which were in possession of special information which had not at that time been transmitted to the Lake Survey office.

The table of estimated precipitation, Table 48, is made up from the published information in regard to precipitation which is to be found in the records of Government observations, including those which were collected by the Smithsonian Institution; those which were obtained while the Weather Service was under the United States Army, and those more accurate ones which have been presented by the work of the United States Weather Bureau as latterly constituted.

Table 53 showing the quantities of material dredged from the several channels of the St. Clair River, Lake St. Clair and the Detroit River has been compiled from the published reports of the Engineer Officers in charge of the River and Harbor District in which this work has been carried on, as presented in the annual reports of the Chief of Engineers of the United States Army from 1870 to date.

As to the plates, as already said, Plates 1, 2, 3 and 4 are copies of the exhibits of the complainant. Plates 5 and 6 are graphical representations of my own computations. Plates 7 and 8 are photographs of charts published by the United States Lake Survey, with the addition of two parallel lines for the purpose of indicating a particular locality.

Q. Were the computations as represented upon the tables correctly made?

A. To the best of my knowledge, belief and ability and that of my office.

Mr. Wilkerson: How much did you do personally?

A. I outlined practically every table; made preliminary computations of most of them; checked the computations of nearly all, and have watched the construction of every one of them from the time the first pencil mark was made until it was finished, and had received a third or fourth check.

I have devoted a considerable part of the last four years to doing it.

Mr. Adcock: The computations that you have arrived at, and the conclusions you have reached are based upon the series of tables heretofore identified by you, and the facts and circumstances testified to by Complainant's witnesses and the documents identified by them, already in evidence?

A. They are.

Q. Will you state your conclusions as to the accuracy or inaccuracy of the observations made and the results reached by the complainant, taking it up by the different subjects; and also state the basis upon which you reach your conclusions;

and also the method which you have used in arriving at your conclusions?

Mr. Wilkerson: I will not interrupt the witness while he is making this statement, with reference to an explanation of these tables, but I reserve the right in the future to move to strike out of the testimony any statements of the witness which I deem to be statements of an improper conclusion, or which I regard as otherwise incompetent, irrevelant and immaterial.

Mr. Adcock: That is when the statement is concluded, or at some reasonable time afterwards.

Mr. Wilkerson: Yes, after we have had an opportunity to consider it.

Mr. Austrian: So as to give us an opportunity to recall him.

Mr. Wilkerson: Undoubtedly, before his testimony is finished I will concede it to be my duty to indicate to you any such motion as I may have, so that you will have an opportunity to recall the witness and put to him such questions as you conceive to be proper to cover the objectionable matter, if it be manifest it is objectionable from a legal standpoint.

A. The accuracy of the observations on discharge appears from a comparison of observations made at each place, and a comparison of observations made at two places on the Niagara and on the St. Clair Rivers to be equal to that of any similar series of observations known.

However, certain inconsistencies, as will be hereafter shown, appear between the results on the Niagara and those on the other two rivers. But even granting the highest degree of accuracy indicated, the magnitudes measured are so great that the differences due to the diversion considered in this case are too small to be the subject of direct measurement.

On the St. Clair River there are 33 observations referred to the Harbor Beach gauge, in which the reported elevations of Huron and St. Clair were repeated in two or more, giving 21 observations of discharge measured under the same observed conditions, as to the two locations; and these are presented in Table 1 of Exhibit 34. The variations of these discharges range from 600 to 8,600 cubic feet per second, with a mean of 3,305; or the maximum difference is 2.22 per cent., the minimum .15 of one per cent., and the average variation from the mean is .844 of one per cent. of the average discharges.

Mr. Austrian: What do you mean by "mean"?

A. I take the mean discharge of the whole series, and the mean variation.

Q. By that you mean average?

A. The average variation from the mean would be one-half of the mean variation; that is, assuming that the variation is above and below, so that the average from the mean would be one-half of the mean variation.

Taking the Grand Trunk gauge instead of that of Harbor Beach, there are 33 observations giving 18 comparisons shown in Table 2; of which the maximum variation is 8,600, the minimum 400 and the mean 3,350 cubic feet per second. And giving the maximum difference as 2.14 per cent., the minimum as 0.104 of one per cent. and the average variation from the mean .831 of one per cent. of the average discharges.

On the Niagara River at the Bridge Section are 40 observations giving comparisons of two or more with the same stage reported for Lake Erie and shown in Table 3, and from these 23 comparisons are obtained giving a variation ranging from zero to 21,600 cubic feet per second, with an average of 4,578 cubic feet per second. The maximum difference is 5.27 per cent., the minimum, zero; the average variation from the mean 1.202 per cent. of the average discharges.

On the Niagara River at the Open Section there are 54 observations at the same stage of Lake Erie shown in Table 4, giving 29 comparisons, with differences ranging from zero to 7,800 cubic feet per second, and a mean variation of 2,962 cubic feet per second. The maximum difference is 2.007 per cent., the minimum zero, and the average variation from the mean .79 of one per cent. of the average discharges.

On the St. Lawrence River, the discharges refer to the gauge at Ogdensburg, and does not include the full fluctuations of Lake Ontario. The gauge location is over 60 miles from the lake and the gauging station some 15 miles further. There are 51 comparable observations which are shown in Table 5 giving 36 differences ranging from zero to 4,200 cubic feet per second, with an average of 1792. The maximum difference is .844 of one per cent.; the minimum, zero, and the average variation from the mean .37 of one per cent. of the average discharges.

If these last gaugings were referred to the actual simultaneous elevations of Lake Ontario, it is improbable that they would show a degree of accuracy above those on the St. Clair River, there being an advantage so far as the gaugings are concerned in the reference to the near-by gauge.

A comparison of the St. Clair gaugings is shown in Tables 6 and 7, based upon the gaugings in 1908, 1909 and 1910, a part of them being at the original or Dry Dock Section, and a part

of them at the Gorge Section of the St. Clair River. The Dry Dock Section is below and the Gorge Section above the mouth of Black River, which probably contributed from 100 to 200 cubic feet per second to the flow of the river.

On account of the Lakes Huron and St. Clair being alike involved—

Mr. Adcock: Just a moment: On those Tables, 1 to 5 inclusive, at the top there are numbers stated. What are those figures underneath there, what do they indicate?

A. Those are the numbers of the experiment as numbered in the records of the complainant.

Q. When you say "experiment" you mean of the observation?

A. Of the observation as numbered in the records of the complainant corresponding to the numbers in the first column on Williams' Exhibit 21.

The second column gives the elevation of Lake Huron, as given in the third column of Exhibit 21.

Mr. Wilkerson: You are speaking of Table 6?

A. Table 1.

Mr. Adcock: All the rest are in the same way.

A. Column 3 headed "St. Clair elevation" corresponds to the fourth column of Exhibit 21.

The fourth column headed "Discharge" corresponds to the last column of Exhibit 21. The column headed "Difference" is the difference between the two discharges which is seen in the fourth column; and the percent variation from mean is the percentage which this difference is of the mean discharge of the two measurements considered.

Q. Then they are arranged in groups, where Huron and St. Clair were at the same elevation, is that right?

A. Yes, sir, and are arranged in order of elevation of Lake St. Clair.

Q. So that if the observations should indicate the exact discharge, they ought to be the same in each group, ought they not?

A. That would be expected if there were no conditions which are unaccounted for in the discharge.

Q. That is, you have the elevation of the lake the same?

A. The elevation of the two lakes the same.

Q. The two lakes being the same?

A. The slope of the river, the fall of the river is the same.

Q. Why do you take Huron and St. Clair at the same elevations?

A. Because both lakes affect the discharge of the St. Clair River, and it would not be proper to consider only one of them, as the variation in position of the other would influence the discharge.

Q. Will you indicate just how that would affect the discharge, that is, the raising of St. Clair?

A. If St. Clair were to rise, it would decrease the fall between Huron and St. Clair. The flow in the river is dependent upon this fall to overcome the resistancies which are encountered in the motion of the water, so that if the fall be decreased, the forces which are to overcome the resistencies are decreased, and the discharge is reduced.

Q. And the velocity is decreased?

A. The velocity is reduced, and the change of velocity is greater than the change in section which may result from the raising of the lower part of the river.

Q. That is the area of the cross-section?

A. That is the area of the cross-section is increased by the raising of Lake St. Clair, but the change in velocity is greater in proportion, so that the net result is a reduction in the discharge.

Q. Now will you continue your answer to the general question?

Mr. Wilkerson: In regard to this first table, take this Table 1, take the fifth line, Huron elevation?

A. St. Clair elevation is 575.36; the ditto marks have not been put in, but the St. Clair elevation appears until it is changed in the column.

Q. There is a difference there of 6,000?

A. Yes.

Q. As to those two particular observations. Might the fact that one observation was made when the river was in the rising stage and another when it was in the falling stage, might that factor account for that difference?

A. It would very likely account for it, and that is one of sources of inaccuracy of current meter gaugings.

Q. But in a long series of observations, the river being in a rising stage about as often as it is fallen, that will be eliminated to a much greater extent than if you compared two observations?

A. Certainly.

Q. That is the thought I had in mind, that I wanted to get clear.

A. Or stated another way, the average of a large number

of results will be more accurate than the average of a small number of results.

Q. Then the comparison of two?

A. Assuming them to be taken under general conditions.

Continuing the comparison of the St. Clair observations, on account of Lakes Huron and St. Clair, both being involved, it is difficult to find observations at each section when both were at the same elevation, but some instances of the kind are shown in the lower half of Table 7. In four of the six cases presented—

Mr. Wilkerson: By the lower part, you mean commencing with which line?

A. I mean in the lower portion of the table. There are two tables on 7, one marked "By Single Observations."

Q. The one headed "By Single Observations?"

A. Yes, the one headed "By Single Observations."

In four of the six cases presented there was a difference of .01 in the elevation of Lake St. Clair, and in one a similar difference in that of Huron. These differences have been corrected by the values for the separate increments computed in Table 24. The observed differences for similar conditions when so corrected at the two sections range from 380 to 2,410 cubic feet per second. If the corrections had not been made, the difference would still remain at approximately the same figures. The corrections are indicated in this sixth column.

In the upper part of Table 7 is presented the comparison of the groups of observations which have been assembled in Table 6; corrections of variations of either lake being made as in the previously considered case.

Then in Table 6, I have given the individual observations which are considered at each location, and we have taken the means of these several groups to make the comparison that is presented in the upper portion of Table 7. The differences here range from 140 to 4,172 cubic feet per second; the mean being 1,851 cubic feet per second. The maximum difference is 2.24 per cent., the minimum .75 of one per cent. and the mean less than one per cent. of the average discharges.

Further evidence of the accuracy of discharge measurements of the St. Clair River is to be found in a comparison of Tables 24, 31 and 33, showing the results of the 1899 and 1902 gaugings, with Tables 27, 37 and 39 of the 1908 and 1910 gaugings. The observations of the earlier table were in general at higher stages than the later ones, so that the center of gravity of the lower half in Table 33 is at very nearly the same

elevation as the center of gravity of the upper half of Table 39.

Mr. Adcock: What do you mean by the center of gravity?

A. The observations of these tables are divided into two groups, first the center of gravity, or the mean point or the mean of both lake stage and the discharge is taken. This divides the observations into two groups, and the mean point or centers of gravity of the upper portion and the lower portion are then taken. This gives three points on the straight line, which most nearly represent the observations that are included.

Q. Is that a well known method of getting at the correct, true line showing the center of gravity of all the observations?

A. That is the mathematically accurate method of deriving the straight line which most nearly fits a series of points.

Q. Is that a line such as is referred to in Complainant's Exhibits 1 to 4 inclusive?

A. It is the line which the complainant was endeavoring to locate, by a purely ocular method of stretching a string across his observations. It might have been mathematically computed by the process which has been indicated here, and which I may say is based upon the well known theory of moments in mechanics.

Q. How did they get their line?

A. The points were plotted and a string was stretched across the plotting and adjusted by the eye until it seemed to fit most nearly the position of the points.

Q. Will you continue the answer?

A. By the former table, Table 33, a stage of 580.404 of Lake Huron corresponded to a discharge of 189,064 cubic feet per second, and the increment was 28,872.

By the latter table, Table 39, a stage of 580.460 of Lake Huron corresponds to a discharge of 191,591 cubic feet per second. The difference between 580.460 and 580.404 is .056 foot, and the increase in discharge due to this increased stage by Table 33 would be 28,872 times .056, equals 1,617 cubic feet per second, which added to the discharge at 580.404 gives 189,064 plus 1,617 equals 190,681 as the discharge by the 1899 to 1902 gagings corresponding to the elevation at which a discharge of 191,591 cubic feet per second was found in 1908 to 1910; thus showing a difference in observed discharged capacity of 910 cubic feet per second, or less than one-half of one per cent.

In view of the fact that during these later observations the Detroit River was obstructed by the Livingstone Channel cof-

fer dam, which is stated to have raised the water above it about 2 inches, thus decreasing the flow, it is interesting to note that the later measurements show the larger discharge.

Q. You say it is stated to have raised the water about two inches? That is from gauge records which you have?

A. That is shown by gauge records which I have, but was stated by Colonel Mason M. Patrick upon oath on the witness stand before the International Joint Commission at a hearing in Detroit within the past month in my presence.

Q. Who is Colonel Patrick?

A. He is the engineer officer in charge of the river improvements on the Detroit River at the present time, located at Detroit.

Mr. Austrian: He is a government officer?

A. He is a United States engineer officer.

Mr. Adcock: If there is any question about that fact as to the raising there of two inches on account of the coffer dam, if you let us know, we will verify it by some other method.

Mr. Wilkerson: We will check the statement. If there is any question we will let you know so that you can make your proof in your own way.

The Witness: For the Niagara River, Table 8 shows a comparison of the gagings at the Bridge and Open Sections, the comparison being made between the mean results at the several stages.

For 1899, the observations show a maximum positive difference of plus 1.03 per cent. and a maximum negative difference of minus 9.06 per cent. of the average discharge, with the Bridge Section positive; the Open Section discharge being the greater in seven out of nine comparisons.

Q. What do those negative and positive quantities mean?

A. I considered the bridge section as being a positive quantity and subtracted the discharge of the Open Section from it, so that if the Open Section discharge were greater than the discharge of the Bridge Section my result would be negative.

Q. That is you arbitrarily in this Table 8——

A. I arbitrarily subtracted the Open Section from the Bridge Section in each case and gave the result the algebraic sign.

Q. And indicated the Bridge Section positive and the Open Section Negative?

A. Yes. Combining the 1898 and 1899 observations in Table 9, we get the maximum positive difference as 3.75 per

cent., the maximum negative difference minus 2.06 per cent.; the bridge section being positive as before. In this comparison, the Bridge Section shows the higher discharges in 21, and the open section in four cases.

Combining the 1898 and the 1900 observations in Table 10, the maximum positive difference is 4.5 per cent., the maximum negative difference is 0.3 per cent. The Bridge Section shows the higher discharge eight times and the Open Section once.

Combining the 1899 and 1900 work in the bottom of Table 10, there is no positive variation, the difference being all negative and ranging from minus 7.5 per cent. to 1.58 per cent. It will be seen by comparing these results with those on the St. Clair that the agreement of these observations is only about half as close as those in the St. Clair River.

If we compute the discharge of the Niagara River from the monthly mean stages of Lake Erie at Buffalo, by the equations derived by the complainant, which computations are shown on Tables 11 and 12, from 1900 to 1907, inclusive, we have an average discharge at the Bridge Section, by the equation derived from the Bridge Section observations of 201,436 cubic feet per second, and at the Open Section of 198,-708 cubic feet per second, a difference of 2,728 cubic feet, or 1.36 per cent. of the mean.

Q. When you say "by the equations derived by the complainant," what do you mean?

A. I mean by the use of the increments which the complainant has introduced in its testimony in this case, the increment being applied for an elevation of 571, with a discharge of 175,000 cubic feet per second in the case of the Bridge Section, and for the same elevation with a discharge of 172,-600 cubic feet per second in the case of the Open Section.

Q. That was for the Niagara River?

A. Yes. I should state that the elevations of Lake Erie at the Buffalo gage have been derived from the report of the International Waterways Commission on the regulation of Lake Erie for 1910, being marked Williams Exhibit 33D.

Considering the relative reliability of the several sources of observations, the observations on the St. Clair River cover periods in five different years for the original group, and two additional years for the subsequent group, while those at the Niagara are confined to three years, and those on the St. Lawrence to two years.

The observations on the St. Clair, as testified to by the complainant, have covered a range of stage from 579.65 to

581.39 approximately; on the Niagara from 570.00 to 573.92 at the Bridge Section and 570.67 to 573.41 at the Open Section, approximately. And on the St. Lawrence from elevation 242.85 to 245.28 approximately.

From 1890 to 1907, inclusive, Lake Huron at Harbor Beach has ranged in monthly mean elevation from 579.02 to 581.71; Lake Erie at Buffalo from 570.79 to 573.92, and Lake Ontario at Ogdensburg from 242.66 to 246.82.

The method of gaging and the location of the section on the St. Clair River leads me to expect more reliable results than on either of the other rivers, and the range of stage covered relatively to the lake fluctuations give a larger proportion of the lake variations included than on the St. Lawrence, the former covering 65 per cent. and the latter 58 per cent. of the lake range.

Q. Just what do you mean, with reference to that latter statement, as to the range of stage?

A. That the actual observations covered a larger percentage of the rise and fall of the lake, of the space passed over by the lake in its natural rise and fall by monthly means in the case of the St. Clair than it did cover in the case of the St. Lawrence, and of course the greater range that you cover with your observations, the more accurately can you determine the relation of changes of elevation to the discharge, assuming the same degree of accuracy in both sets of observations.

Q. Well, is it necessary in order to get accurate results from the discharges of rivers in determining the increment, that the observations cover the range of stage of the lake normally?

A. Well, it is not necessary that they should cover the entire range, but the more nearly they cover it, the more accurately the increment is determined. That is the greater the range between the high and low points of the lake in the observations used for the determination of the increment, assuming equal accuracy for all observations, the more accurately would the increment be determined.

Gagings of the St. Lawrence River from the Bridge at Valley Field, with which I was associated in 1909, give a discharge about 5 per cent. higher than would be indicated by the United States Lake Survey measurements when corrected for the added drainage area.

From all the foregoing, it is my conclusion that the St. Clair gagings as representing changes of discharge due to varia-

tions of lake level are intrinsically more accurate than those of Niagara, and, when the location of the reference gage is considered, more accurate than those of the St. Lawrence. The close coincidence of the 1899 to the 1902 results with those of 1908, 1909 and 1910, and the proved close coincidence of the latter, by the Dry Dock and Gorge comparisons, establishes in my mind beyond question the rank of the St. Clair measurements as the first among those considered.

It however appears that with all their care, experience and scientific apparatus, which I may say I believe has not been exceeded in any series of similar observations that have ever been undertaken, the government engineers by the complainant's method of deduction, are unable to detect variations of 3,000 to 4,000 cubic feet per second in the discharge of the St. Clair and Niagara Rivers; and by their discharge equations for the Niagara, there is a difference of nearly 3,000 cubic feet per second in the average discharge of eight years.

Q. Mr. Williams, in the measurement of the discharge of large rivers like the St. Clair, St. Lawrence and the Niagara, is there anything to which you can tie the observations of the discharge, from which you can determine the accuracy or inaccuracy of the measurements.

A. No, there is nothing outside of the measurements themselves. Of course we could detect an inconsistent observation, as one, for instance, that might show a larger discharge for a lower stage of the lake, we would say on the face of it that was wrong, but that would be on the evidence of the observations themselves. There is nothing outside of the observations to which you can tie them to determine their accuracy.

Q. Take for instance, a case where observations were made 1896 under the conditions, natural conditions which existed, showing a certain discharge of the river, certain volume; then suppose that in 1900 a diversion at some other point than the ordinary outlet had been made of 10,000 to 14,000 cubic feet of water per second; and suppose that, say in the year 1907, under natural conditions, you then make a series of discharge observations, would you be able to detect from the observations made in 1896 or observations made in the latter period in 1907, the obstruction or diversion of water at some other point.

Mr. Wilkerson: I object to that. It is a hypothetical question and does not pretend to include all the elements to be considered in this case.

A. You would not. I just want to correct that answer. I

understand that this question applies to measurements in any of the rivers that are outlets of the Great Lakes, and that the quantity involved is that mentioned near the beginning of the inquiry, from 10,000 to 14,000 cubic feet per second.

Q. Yes.

A. My answer is no.

Q. Will you state your reasons why you could not?

A. Because there are so many other conditions which enter in to affect the outflow of the lakes that having simply the gagings at the two periods, if nothing were known of this diversion by the parties making the gagings, they would be unable,—they would not be able in their gagings to find anything that would lead them to even suspect that such a diversion were taking place, because of the uncertainty of the large number of other factors that enter in, particularly rainfall and evaporation and the effects of ice.

Mr. Wilkerson: Suppose the other factors all remained fixed, could you tell it?

A. If they had all remained fixed, it could be told, not in its full magnitude, but that there was a diversion.

Mr. Adcock: You could not tell how much?

A. Not accurately. A diversion of the amount, of 10,000 cubic feet, would be detected in the measurement if all other conditions had remained the same during the periods intervening.

Q. Would you be likely to find the conditions, all conditions the same in two periods of measurements?

A. It would be about as easy as to find two leaves alike on a tree.

Q. Now, Mr. Williams, have you made any computations and calculations as to the increments, or have you derived any increments from the discharge measurements of the St. Clair, Niagara and St. Lawrence Rivers?

A. I have.

Q. Will you state what increments you have derived, how you have derived them, and the methods used in making your derivations?

A. I first examined the increments as derived or as presented by the complainant in his Exhibits 1, 2, 3 and 4, with a view to ascertaining the accuracy with which those increments had been derived from the data which had been used. I then investigated to see what would be the effect upon the increments had data which the complainant did not include in his derivation been introduced, introducing separately the

gagings of 1908 and 1901, first as corrected by the complainant, and second as actually observed.

Those computations are indicated upon tables 13, 14 and 15. Table 13 represents the computations, or the results of the computations for determining the increment upon the principle which was attempted to be applied by the complainant in the derivation of its increment in Complainant's Exhibit 1, and is based upon the observations of 1899, 1900 and 1902; the observations of 1901 having been neglected, upon the assumed ground that they do not represent normal conditions, and the observations of 1908 having been received too late to have been included in the computation at the time it was made, if I understand the circumstances correctly.

Applying the mathematical method of determining the three centers of gravity of the whole group and the two divisions of the group into which the center of gravity of the whole divides it, we find that the increment as represented by observations from *A* to *U*, giving each equal weight, would be 24,157 cubic feet per second as compared with the complainant's rough and ready determination, or approximate determination, by means of stretching a string of 23,820.

Q. The groups *A* to *U* inclusive, are those the groups of observations which the complainant used?

A. They are the groups of observations shown on Williams' Exhibit 21, which were used by the complainant and are indicated by the letters on this Exhibit 1.

Q. Is the line shown on chart, plate—

A. Plate 1 shows the complainant's line, the line of these observations—this reduction has not been put upon that chart.

Q. And plate 5?

Mr. Wilkerson: Q. There would not be very much difference?

A. No, it is only about 1½ per cent.

Q. That is, if you draw the line on plate 1, the lines are pretty near together?

A. The top of it would be a little bit lower than the line that is drawn there. I must say that as a piece of work of stretching a string, it was an excellent job of stretching.

Mr. Adcock: Q. And does plate 5 show the line which you have—

A. No, it does not. That refers to another determination of an increment to which we will come later on.

By a similar examination of the data, including the obser-

vations of 1908 which are presented in table 14, I find that had this data all been included and the observations given equal weight and the line mathematically determined, the increment would have been about 3½ per cent. higher than the value appearing on the complainant's chart.

Q. How does that table differ from table 13?

A. By the introduction of the observations of 1908, which are indicated by the letter Alpha and *Z*.

Mr. Wilkerson: Q. I want to ask you this question: You combine here different cross-sections. Now, there are certain fixed errors, are there not, where you have different cross-sections, which make it improper, if I may use that word, to combine the different cross-sections in figuring the increment?

A. I fail to see that. The increment is referred to the stage of lake, not to the stage at the gaging station, as I understand these observations. If this increment for each place has been figured with reference to a gage at a gaging station, then I have misunderstood the trend of the complainant's testimony entirely, and I would say that the deductions which have been drawn from it are absolutely incorrect. It is my understanding that the same reference gage is used, both in the Gorge measurements and in the Dry Dock measurements as presented in its table. If that is not the case, then these computations—

(Former answer of witness read as follows: "By the introduction of the observations of 1908, which are indicated by the letter Alpha and *Z*.")

The witness (continuing answer): On table 15 are presented the computations when introducing in addition to the observations of 1908 the observations of 1901, first using the corrected value adopted by the complainant. This is shown in the fourth column, and the increment is shown at the bottom of the page. Introducing these observations as adjusted or corrected by the complainant, the increment derived is about 2½ per cent. greater than that presented on Complainant's Exhibit 1.

Mr. Wilkerson: Q. That is 24,436?

A. 24,436. It is intimated by the complainant's witness, in file 7 at page 82 of the record, continuous paging 630, that excluding the 1901 observations gave an increment favorable to the contentions of the defendant. If, however, the observations of 1901 be included with all the rest without correction, the resulting increment as shown on table 15, in the third, sixth and seventh columns is 27,861 cubic feet or nearly 17

per cent. greater than that given on the chart; and if the increment be increased, the effect of the diversion is decreased and the foregoing suggestion of the complainant's witness is therefore shown to be an error.

In this table 15, the first column indicates by letter the groups of observations as they have been used; column 2 indicates the average elevation of Lake Huron for each group of observations in question as given upon Williams' Exhibit 21.

Column 3 is three centers of gravity of the elevations. Column 4 is the value of the discharge with the corrected values for 1901 included. Column 5 gives the centers of gravity of these discharges in Column 4. Column 6 gives the observed discharges without correction. Column 7 gives the centers of gravity or means of these observed discharges, and the increment then is as stated and shown in the bottom line of the table, 27,861 cubic feet per second.

Mr. Adcock: Q. You say "corrected values for 1901." What do you mean by that, Mr. Williams?

A. In Complainant's Exhibit 21, at the foot of that table, referring to discharge measurements, Dry Dock Section St. Clair River, 1901, we find this note: "Discharge was decreased two-thirds of one per cent. for each tenth foot Lake St. Clair was below normal as expressed by equation; St. Clair equals 574.79 plus 0.66 (Harbor Beach minus 580)." This correction to these observations has been made in accordance with that equation and introduced to cover groups *V*, *W*. and *X* in the fourth column of table 15.

Q. Why were those corrections made, if you know?

A. On the assumption of the complainant that Lake St. Clair was in an abnormal position with reference to Lake Michigan. In other words, that it was too low, and therefore the discharge measured was higher than would have existed with St. Clair in its normal position.

Adjourned to Thursday, March 20, 1913, at 10 a. m.

March 20, 1913, 10 a. m.

GARDNER S. WILLIAMS resumed the stand and testified further as follows:

Mr. Adcock: During the period of these gagings on the St. Clair, 1899, 1900, 1901 and 1902, what was the relation of the stages at St. Clair and Huron during those periods, as compared with the normal relation?

A. Your question is with reference to St. Clair and Huron?

Q. St. Clair and Huron.

A. The relations between Lakes St. Clair and Huron are shown on Table 17, in which the monthly mean elevations of Lakes Huron and St. Clair are shown in Columns 3 and 4 respectively for the months during which gagings were in progress on the St. Clair River, during the several years indicated in Column 1.

Column 5 shows the difference or fall from Huron to St. Clair. Column 6 gives the number of gagings each month, and the seventh column shows the weighted difference, or rather the difference multiplied by the number of gagings, the mean weighted difference being indicated in the eighth column.

And finally, in Columns 9 and 10 we have for each year the mean weighted elevations of Lakes Huron and St. Clair during the period of gaging, the weightings being dependent upon the number of gagings that were taken each month.

Q. Now will you explain just a little bit more in detail what you mean by weighting measurements or observations?

A. Yes. If during any month there had been one gaging, that difference of elevation, or the elevation for that month in the weighting would have been given a weight of one. If in the next month there were, say, 10 gagings, the elevations, the differences of elevations would have been given a weight of 10. And in the summation for those two, if they only were involved, the sum of the weights for the two months would be divided by 11, that is the sum of the number of gagings; thereby getting an average elevation or difference of elevation for the series of gagings. It happens that the number of gagings per month does not vary greatly. The highest number during 1899 is 16, which occurs in both July and November. The lowest number is seven, which occurs in September.

In 1900, the range was from 19 in December to seven, which occurred both in June and November. In 1901 there are but

two months, May having 16 and June 20. In 1902 there are two months, August having 18 and September 30; 1908 there are two months, November having 12 and December three. For the entire period covered by the gagings from 1899 to 1908, inclusive, the mean elevation of Lake Huron was 580.644, as derived by the previously described weighting, and that of St. Clair, corresponding, was 575.174, showing a fall from Lake Huron to Lake St. Clair of 5.47 as the weighted mean fall.

Q. That is feet?

A. 5.47 feet as the weighted mean fall during the periods of gagings involved.

Comparing this with Table 19 it is found in the second column, the third line from the bottom, the mean elevation of Lake Huron as given by the exhibits for the Lakes Michigan and Huron in Williams Exhibit 26, for the period from 1860 to 1908, inclusive, was 581.36. The mean elevation of Lake St. Clair as given in the said exhibits, and extended by the aid of the tables in the report of the International Waterways Commission, being Table 7, Water Levels of Lake St. Clair, page 90, or Exhibit 33 A-. The reason for reference to the report of the International Waterways Commission being that the gage elevations supplied by the United States Lake Survey for the St. Clair Flats begin with July, 1872, and that there are omissions in 1877, 1878, 1879, 1880, 1881, 1882 and 1883; also in 1902 and 1903. And in order to get a comparison it was necessary to have the record extended, for which purpose reference was made to the work of the International Waterways Commission. The mean elevation of Lake St. Clair so derived is 575.76, showing a difference or fall of 5.6 between the two lakes, as compared with 5.47 as derived on Table 17.

A similar comparison may be made by reference to Table 18 with the open season elevations, by open season understanding the period from April 1st to November 30th, inclusive. From 1860 to 1910 the mean elevation of Lake Huron was 581.52. The mean elevation of St. Clair, similarly derived to that testified regarding Table 19 was 575.98; giving a mean fall of 5.54 feet as compared with the 5.47 feet as shown on Table 17. Inasmuch as the records of Lake St. Clair for the period prior to 1872 have been derived by comparison with other gages, it has been thought wise to make a comparison between the elevations of Lake Huron and Lake Erie, both during the gaging periods, and during the period from 1860 to 1908, for the rea-

son that we have a continuous record of the elevations of Lake Erie, and that there is a relation between the elevation of Lake Erie and Lake St. Clair and Lake Huron, which is approximately constant for a large part of the time considered.

Table 16 presented in a similar manner to Table 17 differences of elevation between Lakes Huron and Erie during the months of discharge mentioned. The preparation and treatment of data in this table is similar to that in Table 17, the elevation of Lake Erie as taken from the tables of lake elevations in Williams Exhibit 26 being used in place of the elevations of Lake St. Clair, which, as before stated, were partially derived from Exhibit 26 and partially from the report of the International Waterways Commission, Exhibit 33.

At the bottom of Table 16, in the column headed "Mean Difference," second line from the bottom, we have the mean fall for the gaging periods, being the weighted mean fall from Lake Huron to Lake Erie given as 8.61 feet; the weighted mean elevation of Lake Erie being 572.033.

Referring now to Table 18 for the open season, the last page of the table, the third line from the bottom, we find as before the mean elevation of Lake Huron from 1860 to 1908 to have been 581.56, and in the next to the last column of the table, the third line from the bottom, the mean elevation of Erie for the same period to have been 572.85, showing a difference of 8.71 feet, as contrasted with the difference between these lakes in Table 16 of 8.61 feet. That is for the gaging period, using all the years included from 1899 to 1908. If the observations of 1901 be omitted, we have shown in the bottom line of Table 16, the mean weighted elevation of Lake Huron to have been 580.608, and the mean weighted elevation of Lake Erie to have been 572.115, giving a mean fall between the two lakes as shown in the column headed "Mean Difference" of 8.49 of a foot.

It therefore appears that between the mean elevations of these lakes for the open season and the weighted mean elevation as derived in Table 16 for the gaging periods, exclusive of 1901, there is a difference of over two-tenths of a foot, and if compared with the mean elevation of the lakes, as shown in Table 19, which embraces the full year, we have the mean elevation of Lake Huron given in the third line from the bottom of the last page of the table from 1860 to 1908 as 581.36, and the mean elevation of Lake Erie for the same period as 572.61, giving a difference of elevation of 8.75 feet, or nearly

.3 of a foot greater than that obtained by the use of the observations of the complainant, excluding 1901.

Table 19 is intended to be, so far as Columns 2, 4 and 6 are concerned, an accurate transcript of the mean elevations for the lakes in question as shown upon Williams Exhibit 26, furnished by the United States Lake Survey, with the additions from page 90 of the report of the International Waterways Commission necessary to complete the record of Lake St. Clair.

This change in fall has been due mainly, or we may say fully speaking relatively, to the fact that Huron was higher as an average from 1860 to 1908, than it was during the periods of gauging, by approximately .3 of a foot. And referring to the complainant's testimony as given in File 7, page 60, of the original record, or continuous paging 608, wherein it was stated that if the other lakes remained stationary, or more specifically if Lake St. Clair remained stationary and Lake Huron should raise .2 of a foot, the discharge would be increased 6,570 cubic feet per second, then it would follow, if Lake Huron had been .3 of a foot higher during these gaugings, the discharge would then have been increased by about 9,855 cubic feet per second.

If we were to take the actual differences of elevation between these lakes, the discharge of the St. Clair River would, according to our own computations, as will be explained later, have been something over 20,000 cubic feet per second greater, had the stages of the lakes been at their average position for the period from 1860 to 1908 instead of in the positions which they actually did occupy during the gauging period.

If the 1901 gaugings be included, the average difference of elevation between Huron and Erie, as already pointed out, during the period of gaugings as shown in Table 16, was 8.61 feet, or 50 per cent. nearer to the normal difference of elevation as established from the open season records of the 49 years from 1860 to 1908 than is the fall derived from the observations without 1901, which seems to be that used in the derivation of Complainant's Exhibit 1 of the increment of the St. Clair River. And it has therefore been concluded by me that the value of the increment derived from all these observations being based solely upon a variation of elevation of Lake Michigan-Huron is a more nearly correct value to be applied than the one adopted by the complainant; that value being 27,861 cubic feet per second.

It may be remarked here that the complainant's witness,

Mr. Wheeler, File 4, page 45 or page 141 of the continuously paged record, gives the St. Clair increment from his own computations as 25,300 cubic feet per second.

Q. Upon what theory, as shown by the testimony adduced by complainant, are the increments for the St. Clair River derived, and what errors of assumption appear to you in that derivation?

A. The increments derived by the complainant for the St. Clair River are based on the assumption that an increment can be derived for that stream without reference to Lake St. Clair, and that the observations considered are sufficient for that purpose. While it is probable that if for a sufficient period of years gaugings were made every day so as to cover all possible positions of both Lake Huron and Lake St. Clair, and no changes occurred in the channels connecting the two meanwhile, the assumption of the complainant might lead to accurate results. A comparison of the conditions existing between the two lakes during the gauging periods as shown in Table 17 with the average conditions existing as shown in Tables 18 or 19, being Williams' Exhibit 34, shows the incorrectness of the assumption with the limited number of observations thus far made, for while the average fall between these lakes for the periods of gauging as shown on Table 17 was 5.47 feet, the average fall for the full year for the period from 1860 to 1908, as shown on Table 19, third line from the bottom, was 5.6 feet. Since the velocity in an open channel is very nearly proportional to the square root of the fall, other things remaining the same, the increased fall for the latter period would theoretically increase the velocity by the square root of 5.60 divided by the square root of 5.47, or by about 1.2 per cent.

The discharge would be further influenced by the elevation of Lake Huron. During the gaugings, the mean elevation of Lake Huron as shown in Williams' Exhibit 24, and compiled in table 19 of Exhibit 34, from 1860 to 1908 was 581.36. If we accept for the purpose of this discussion the contention of the complainant that there has been no change in the conditions of outflow of the St. Clair River, it appears that the depth of water at the head of the river in which the discharge measurements were made, was .65 of a foot less during the measurements than during the average of the 49 years under consideration.

Q. Look at the printed book which I now hand you and state what that is?

A. This is Appendix III to the report of the Chief of Engineers for 1900, of which pages 5379 and 5380 show in the seventh column the area of the Dry Dock Section used in gauging the St. Clair River as 60,935 square feet. The width of the section is stated on page 5364 to have been a little over 2100 feet, and the depth is shown on Plate 12 of the same report as approximately 35 feet, over something more than half of the section.

Mr. Adcock: We offer for identification pages 5362 to 5401 inclusive of the Report above described for 1900. And it is stipulated between counsel that the book itself need not be marked, but that it may be considered as identified so as to avoid the necessity of encumbering the record with so large a publication.

Mr. Wilkerson: Either such portions as are indicated or such other portions of the report as we may wish to direct attention to if occasion requires.

The Witness: If the depth were increased .65 of a foot, there would be an added area of at least .65 times 2100 or 1365 square feet, or about 2 1/4 per cent. of the total cross section. This added depth increases the hydraulic mean depth so-called from about 28 to about 28.7 and increases the discharge approximately in the ratio of the square roots of these mean depths, or as the square root of 28.7 divided by the square root of 28, which gives an increase of about 1 per cent.

The combined influence of increased slope, increased area and increased depth are then 1.012 multiplied by 1.0225 multiplied by 1.01 equals 1.045 and the average discharge of the St. Clair River, if there have been no changes in the channel affecting the discharge must have been very nearly 4 1/2 per cent. above the gaugings of 1899 to 1902 as an average of the period of 1860 to 1908. And if the discharge were increased, the increment in all probability would have been increased to some extent. The increment deduced by the complainant would indicate that the quantity of flow under average conditions for the open season, when the difference in stage of Huron is .92 of a foot.

By tables seventeen and eighteen, higher than during the average of the gaugings, must have been fully 10 per cent. greater than that observed.

In other words, during the average period from 1860 to 1908, the discharge through the St. Clair River must have been something over 20,000 cubic feet a second greater than

it was during the periods in 1899, 1900, 1901, 1902 and 1908, when the complainant made its gaugings.

However, as it appears to me that the normal relations between Lakes Huron, Erie and St. Clair as established by the relative positions by the annual elevations of those lakes for the period from 1860 to 1908, inclusive, did not exist during the period covered by the observations, I think it necessary to derive an increment in such a manner that it can be applied with the normal relation to get a more accurate value of the discharge, and consequently of the effects of diversions. To do this, the influences of Lakes St. Clair and Huron must be separated, which may be done by determining increments for the effect of each when each lake was at a constant elevation, and the other changing. If the observations from 1899 to 1908, inclusive, be arranged in groups with Lake St. Clair at a uniform elevation for each group, which arrangement has been made in table 22 of Exhibit 34, there are fifteen such groups of from four to thirty-one observations, and an increment may be determined from each group, according to the methods already discussed in the examination of the increments derived by the complainant in connection with testimony relative to Tables 1 to 4 of Exhibit 34, and these increments with the essential figures of the computation, therefore, are presented on Table 22 of Exhibit 34.

In this Table 22, column 1 gives the number of observations in each group. Column 2 gives the elevation of Lake St. Clair for the observations in that group. Column 3 gives the elevation of the center of gravity, or the center of gravity of the elevations of Lake Huron for each group; and column 4 gives the center of gravity of the discharges for each group. Column 5 gives the center of gravity of the elevations of Lake Huron for the upper portion of the group; column 6, the center of gravity of the discharge for the upper portion of the group; column 7 the center of gravity of the elevations of Lake Huron for the lower portion of the group; and column 8 the center of gravity of the discharge for the lower portion of the group. Whence the equation in column 9 is derived, and the increment then is the coefficient of Y in said equation, and is shown in column 10. The arithmetic mean of these increments is shown at the bottom of column 10.

There are shown in the Table 15 such groups, of from four to thirty-one observations, and the increments determined from the several groups range from eighteen thousand, six hundred cubic feet per second from a group of

six observations, to forty-four thousand, three hundred and twenty-five cubic feet per second, from a group of fourteen observations. The mean of the fifteen determinations being 34,385 cubic feet per second, as the arithmetic mean, or when weighted by the number of observations in each group as shown in Table 24, the left hand portion, the weighted mean is 36,187 cubic feet per second as the effect of a rise of one foot on Lake Huron on the discharge of the St. Clair River, when Lake St. Clair does not change.

To introduce the effect of Lake St. Clair, we make a similar arrangement of the observations which is shown in Table 23 of Exhibit 34, arranging the observations in groups, with Lake Huron at a uniform elevation for each group.

In column 1 of this table is shown the number of observations in each group; column 2 the elevation of Lake Huron for that group, and columns 3-4, 5-6, 7-8, giving the three centers of gravity of the elevation of Lake St. Clair, and the discharge. Column 9 gives the derived equation and column 10 the increment and the mean of the increment is stated at the bottom of the page.

There are twenty-one groups of from three to seven observations, giving increments ranging from minus thirty-one thousand to plus 12,800, with a mean of 14,072 cubic feet per second, unweighted, or as shown in Table 24, Exhibit 34, a mean of minus 12,995 cubic feet per second, when weighted according to the number of observations in each group, as the effect upon the discharge of the St. Clair River of one foot rise of Lake St. Clair when Lake Huron remains stationary. Or, in other words, when Lake St. Clair rises one foot if there were no other change in the river, the discharge would be decreased 12,995 cubic feet per second, and if Lake Huron raised one foot and there were no other change, the discharge would be increased 36,187 cubic feet per second.

To explain the meaning of the term "weighted", as used in this answer, I would say that we conceive that if a group has three observations, and another group has six observations, that the second group is entitled to twice the reliability of the first group on the theory that all observations are of equal accuracy, and that all are somewhat in error. Therefore, in reducing these observations, we have multiplied the result of each group by the number of observations in it, added those sums, and divide by the total number of observations to get a weighted mean; thereby giving ourselves the benefit of a large number of observations, in which each is

treated as of the same value over the average of the same number of observations, where they would not be treated of the same value if we took the direct or arithmetic mean of the last columns of Tables 22 and 23.

In connection with this method of deriving an increment for the St. Clair River, I would call attention to the testimony of complainant's witness Shenehon, it appearing in file 7, at page 102-103 of the record, or on pages 650 and 651 of the continuous paging of the record, in which the propriety and correctness of an increment derived in this manner was submitted, when, in answer to the question: "Q An increment obtained in that way would be likely to be at least approximately correct," the witness answered "Yes."

Complainant's witness Shenehon, in file 7, page 60 of the record, or at page 608 of the continuous page record, states the back water effect of Lake St. Clair to be about two-thirds of one per cent. of the discharge for one-tenth foot rise, which when applied to the mean of the gaugings of 1889 to 1908, which is given in Table 15, being part of Exhibit 34, in the last column in the middle, as 196,908 cubic feet per second, gives minus 13,130 cubic feet per second as the increment for one foot rise of Lake St. Clair.

It is further stated by the same witness in file 7 at page 58, or page 606 of the continuously paged record, that the normal relation between changes in elevation in Lakes Huron and St. Clair is that 66 per cent. of the change of the former appears in the latter.

I might at this point call attention to the fact that the increment derived from the complainant's testimony above cited, on page 606, of 13,130 cubic feet per second coincides very closely with the value derived in Table 23 of Exhibit 34, as weighted in Table 24 of the same exhibit, which is 12,995 cubic feet per second.

It is also stated by the same witness in file 6, at page 38, or one page 496 of the continuously paged record, that the effect on the elevation of Lake St. Clair is eighty per cent. of the average of the changes in elevation of Huron and Erie, and Lake Erie is stated by the same witness, in file 7, page 43, being page 591 of the continuously paged record, that the elevation of Lake Erie varies by 70 per cent. of the change of the elevation of Lake Huron. Then the mean change of the two lakes, based upon the last two citations, is 1.00 plus .70, divided by 2, equals .85 of the Huron change; and the Lake St. Clair change then is .80 times .85, equals 68 per cent. of

the Huron change. In other words, the testimony of the complainant's witness leads us to substantially the same relation between a change of elevation of Lake Huron and a change of elevation of Lake St. Clair, whether it be derived from the direct statement in file 7 at page 58, or by a combination of the two statements of file 6, page 38, and file 7, page 43.

It then follows that under normal relations, if Lake Huron rose one foot and increased the flow 36,187 cubic feet per second, Lake St. Clair would rise .66 to .68, or say 66 2/3 per cent of a foot, and reduces the discharge by 66 2/3 per cent. of 12,995, or by 8,664 cubic feet per second, leaving the net increment for one foot of change on Lake Huron, under normal conditions, as 36,187 minus 8,664, or 27,523 cubic feet per second, or within 1 1/2 per cent of the value previously obtained by using the 1901 observations with the rest. The value, 27,523, is about 11 per cent. greater than the value mathematically determined from the observations of 1899, 1900, 1902 to 1908 by the previous computation, when the relative elevations of the two lakes were neglected; and over 15 per cent. greater than the value given on Complainant's Exhibit 1.

Recess to 1:45 P. M.

After recess—1:45 P. M.

GARDNER S. WILLIAMS resumed the stand and testified further, as follows:

The relations between the elevations of Huron, St. Clair and Erie, to which the complainant's witness testified in the citations to which reference has just been made, were based apparently upon average conditions from 1860 to 1908; but these conditions changed materially about 1890, and while as shown by Table 21 of Exhibit 34, the changes of annual elevation of St. Clair are about 68 per cent. of those of Huron for the period from 1860 to 1889 inclusive, the changes of elevation of St. Clair for the period from 1891 to 1910, inclusive, are about 89 per cent. of those of Huron.

In Table 21 of Exhibit 34, in the first column, are indicated the periods 1860 to 1889, and 1891 to 1910. In column 2 are given the years; and in column 3 the elevation of Lake Huron for each year enumerated in column 2.

In column 5 is given the elevation of St. Clair for the same years as enumerated in column 2. Column 4 gives the centers of gravity of the two groups, and the whole of the elevations of Lake Huron in column 3 for each of the periods; and column 6 gives the similar centers of gravity for the elevations of Lake St. Clair.

At the foot of the table, under 1860, it is shown by a subtraction of the lower center of gravity, for the period 1860 to 1889, from the upper center of gravity of the same time, that the mean elevation of Lake Huron changed 1.131 feet. During the same time, as shown by the subtraction of the lower center of gravity of the elevation of Lake St. Clair from the upper center of gravity for the same period, the mean elevation of Lake St. Clair changed .767. The ratio of the change of elevation of Lake St. Clair to the change of elevation of Lake Huron is therefore .767, divided by 1.131, or 67.8 per cent., which coincides with the relation testified to by the complainant's witness before cited.

For the period from 1891 to 1910, similarly, subtracting the lower center of gravity of the elevation of Lake Huron from the upper center of gravity for this period, the difference of mean elevation is 0.577. Similarly, for Lake St. Clair, subtracting the lower center of gravity from the upper center of gravity of the elevations as given in column 6, the difference of mean elevations is found to be 0.516.

The ratio of the change of Lake St. Clair to the change of Lake Huron for the period from 1891 to 1910 is therefore found to be 0.516 divided by 0.577, or 89.4%.

If instead of using the relation between St. Clair and Huron, as testified to by the complainant's witness, we use the relation which is derived for the period since the apparent change of conditions in 1891, the increment for the St. Clair River as derived from the computations in Tables 22, 23 and 24 of Exhibit 34 becomes 36,187 minus .89 times 12,995, equals 24,620 cubic feet per second.

In the reduction of the observations for discharge so far considered, it has been assumed that the discharge observed is that due to the elevation of the Lake surfaces existing during the actual gaging. In many observations this was not simultaneously observed, and has been determined, as stated by the complainant's witness in file 6, at page 16, being page 474 of the continuously paged record, by a series of comparisons between a gage at or near the gaging station, and the controlling lake gage. The gage elevations set down as thus

corresponding to the discharge measurements in Exhibit 21 can then be regarded as representing only approximately the conditions producing the discharge, which will also be influenced by the situation of the lake surface during many antecedent hours.

In other words, it is my conception that the discharge of the river cannot instantly respond to a change of lake elevation in its entirety; that while the change of lake elevation increases the discharge of the river immediately, it does not get its full increase, the discharge does not get its full increase due to that change of elevation or that rise of elevation until some time afterwards. The values determined in the preceding investigation and those presented by the complainant, are therefore all subject to an error which has yet been nowhere considered. On account of the inertia of the water, the discharge does not respond instantly to a change of lake elevation, nor is the full effect of a change felt until its influence has traveled through the entire length of the river in question, and caused an acceleration or a retardation of every particle in it, and the rise or fall of stage throughout its full length.

In Appendix EEE of the Report of the Chief of Engineers for 1904, at page 4093 there appears the following statement: "In 6.4 days, therefore, after a rise occurs in Lake Huron, 9/10ths of the resulting rise will have taken place in Lake St. Clair." In other words, it takes, according to this statement, practically a week for the effect of a rise of Lake Huron to travel through the St. Clair river, and the full and final effect of that rise cannot therefore be said to have taken place in that river until after the expiration of this time.

As the change in discharge is an effect of the change in stage, it cannot precede it on any supposition; and on account of the tremendous mass of matter involved, a river of water nearly half a mile wide and forty miles long, weighing about three hundred million tons, the effect cannot be simultaneous or even approximately contemporaneous with the cause, so that it necessarily follows that the variations recorded in Lake stage from one observation to another will ordinarily be greater than the true variation corresponding to the change of discharge.

In other words, changes of discharge obtained by observations on fluctuating reservoirs will under all ordinary circumstances, be too small in relation to the changes of surface elevations. Incidentally it follows that the nearer the gaging

station is to the outlet of the lake, the more closely will the effects there coincide in time with the causes in the lake producing them. To fully correct this error from the observations in hand is impossible.

Mr. Adcock: What do you mean by "The observations in hand?"

A. The observations which have been furnished by the complainant relating to these discharges. And it would require many times the number we now have to eliminate it. But the observations in our possession may be grouped chronologically and periods selected when for a considerable time the range of variation of the lake surfaces was small, and from these groups an increment may be obtained by a more precise method than any yet used, for the conditions existing during the period covered by the observations.

In other words, instead of using a single simultaneous elevation of the lakes at the time of gaging, it is proposed to use the mean of a series of elevations, consecutively observed, and the mean of the gagings during the period over which those elevations extend, to get a more correct relation between change of lake stage and change of discharge.

Examining the data on the St. Clair from 1899 to 1902, we find eleven periods ranging in length from four to ten days, and including from four to eleven discharge measurements, during which the variations of the lake surfaces and the times of the discharge observations were such as to permit the computation of a mean elevation and a corresponding mean discharge, that, in our judgment, should be reasonably representative. These observations, their groupings, are presented in Table 28 of Exhibit 34, comprising three sheets.

These observations were grouped first, by periods when, according to the records furnished by the United States Lake Survey as presented in Williams' Exhibit 28, Lake St. Clair was at a uniform elevation during the full period of each group. They were also selected during such periods as the elevation of Lake Huron appeared to be either approximately constant or as the variations balanced and brought the initial and final position of the lake to substantially the same level.

In the first column of Table 28 is found the number of the group. In the second column is given the date of the observation, and it will be noticed that in each of these groups the elevation of Lake St. Clair has been started one day ahead of the elevation of Lake Huron, and has been stopped one day prior to the cessation of the record of the elevation of Lake Huron.

In the third column is presented the elevation of Lake Huron as indicated on Exhibit 21, and in the fourth column the elevation of Lake St. Clair as presented upon the same exhibit. In the fifth column is presented the mean daily elevation of Lake Huron as shown in Exhibit 28, being the mean daily elevation of Lake Huron at Harbor Beach. In the sixth column is presented the mean daily elevation of Lake St. Clair as shown in Exhibit 28, it being the mean daily elevation at the St. Clair Flats. In the seventh column is presented the observed discharge, which is taken directly from the last column of Exhibit 21.

In the eighth column is indicated the weight given to each discharge, said weight being determined by the length of time which the discharge is assumed to represent, it being assumed to extend or cover one-half the period each way to the next observation of discharge, except in the case of the first observation, when it is assumed to begin at the beginning of the day on which it is taken, and in the case of the last, when it is assumed to terminate at the end of the day on which it is taken.

In the last column of the table are given the products of the weight by the observed discharge, and in the footing of each group the averaged weighted discharge for the period, while the fifth column gives the average elevation of Lake Huron at Harbor Beach; and the sixth column the average elevation of Lake St. Clair at St. Clair Flats.

The data of this table as presented is sufficient to enable the accuracy of the transcription to be checked by comparison with Exhibits 21 and 28.

In this particular table, the discharges have been weighted, as just stated, by the time interval which they are supposed to represent; it being assumed that the discharges represent consecutively the changes of condition in the river from time to time. If a discharge had been taken every day, and only one, there would be no occasion to weight them. We should then simply take the mean of the discharges, but as on some occasions a day elapsed between the measurement of discharges, it becomes necessary to give those discharges which were taken before and after the interval, an additional weight in order to cover the interval in order that the time covered by the discharges may correspond with the time covered by the record of lake elevations.

Mr. Wilkerson: If two observations were taken on three days, you would give each one a weight of one and a half?

A. A weight of one and a half, that is the proposition.

We then have eleven observations showing a mean position of the surface of Lake Huron, mean position of the surface of Lake St. Clair moved twenty-four hours ahead, and the mean discharge observed for this time.

Q. Why do you take twenty-four hour periods?

A. Because we had to cover the full period that the lake was in the position. We could not select periods of elevation of the lake. We are taking a continuous period from the beginning to the end, in order that we may get at the mean position of the lake during that time.

Q. You say you take St. Clair twenty-four hours after Huron?

A. I take it twenty-four hours ahead. I assume the effect of Lake St. Clair, being so much further away from the gaging station, will not bring its full effect to bear as rapidly or as soon as Lake Huron.

Q. Why do you assume twenty-four hours?

A. I might have assumed some other period.

Q. Might have assumed six or eight hours?

A. I would have assumed more rather than less, or six days and a quarter to be precise. In these cases it would have very little bearing, as according to the record Lake St. Clair was at a constant position all the time. We find for several weeks in this record that Lake St. Clair did not vary one-hundreth of a foot.

As there are not a sufficient number of observations to enable us to determine a series of equations for periods of approximately uniform stage, when Lake Huron would be quiescent and Lake St. Clair moving, it is not possible to derive a new increment for the back water effect of Lake St. Clair by a method in harmony with the one which has just been outlined. We would need a great many more observations, and it is doubtful if the process could ever satisfactorily be applied, by reason of the fact that the surface of Lake Huron will not remain stationary for more than a very limited length of time. In view of the fact, however, that the back water effect as derived in my previous computations substantially coincides with that which has been testified to by the complainant, in the further production of an increment from the groups of observations in Table 28 of Exhibit 34, it has been assumed that the back water effect of Lake St. Clair is minus 13,000 cubic feet per second, upon the discharge of the St. Clair River.

In other words, it has been assumed, on the basis of the tes-

timony of the complainant, and the results of my own computations, as set forth in Tables 22, 23 and 24 of Exhibit 34, that the effect of one foot rise of Lake St. Clair upon the discharge of the St. Clair River, is to reduce that discharge 13,000 cubic feet per second.

Accepting for the purpose of argument the statement of the complainant's witness that a rise of one foot in Lake Huron is normally accompanied by a rise of two-thirds of a foot in Lake St. Clair, we proceed to the derivation of an increment by correcting the positions of Lake St. Clair to its normal position, with reference to Lake Huron, in accordance with the above mentioned ratio.

Table 19 of Exhibit 34, presents the first step in this reduction. The mean elevation of Lake Huron for the open season from 1890 to 1910, as has been shown on Table 18, was 580.70; and the mean elevation of Lake St. Clair from 1890 to 1910 was, as shown on the same table, 575.36. And it is assumed that for every change of Lake Huron above or below 580.70, Lake St. Clair should change two-thirds as much from 575.36. We are therefore able, by taking the changes of Lake Huron to compute a normal position for Lake St. Clair.

In Table 29, the first column shows the number of gagings included in the groups. The second column gives number of the groups; the third the days in the groups, and the fourth the period covered by each group, the fifth the average elevation of Lake Huron, all being as indicated in the preceding Table 28. In the sixth column of the table headed "Change from mean," is shown the change of Lake Huron from the mean elevation of 580.70.

In the seventh column is shown the mean elevation of Lake St. Clair as taken from Table 28; and in the last column again marked "Change from mean," is shown the change of Lake St. Clair from the mean position of 575.36.

We now come to Table 30 of Exhibit 34. Column 1 gives the number of the group. Column 2 gives the observed change from mean of Lake Huron. Column 3 gives the observed change from mean of Lake St. Clair, those three columns being taken directly from Table 29. Column 4 gives the normal change of Lake St. Clair; that is, that change corresponding to 66⅔ per cent. of the change of Huron as indicated in Table 2. And Column 5 gives the difference between the normal change of Lake St. Clair and the observed change of Lake St. Clair, with its proper sign, as to whether the normal would have been above or below the observed change. A rise of one

foot in Lake St. Clair being assumed to cause a decrease of discharge of the river of 13,000 cubic feet per second, it is then possible, by multiplying the differences in Column 5 by 13,000 to get the results in Column 6, which are the corrections to the discharge due to the abnormal position of Lake St. Clair.

Column 7 is the observed discharge of the St. Clair River for the period in question, as taken from Table 28. And Column 8 gives the observed discharge plus the correction for the abnormal position of Lake St. Clair in Column 6, and represents, on the foregoing theory, the discharge of the river which would have existed had Lake St. Clair been in its normal relation to Lake Huron, as shown by its average position from 1890 to 1910; assuming, according to the testimony of the complainant, that the change in Lake St. Clair is two-thirds of the change in Lake Huron, and that the effect of one foot rise in Lake St. Clair is to decrease the discharge of the St. Clair River 13,000 cubic feet per second.

Table 31 presents the next step in the computation of the increment. Column 1 again represents the number of the group; Column 2 the mean daily observed position of Lake St. Clair taken from Table 28. Column 3 the corrected discharge taken from Column 8 of Table 30. Column 4, a multiplier being the number of days that are included in each period of gauging, in order that the several values of the several periods may be weighted according to the length of time. Column 5, the corrected discharge multiplied by the factor in Column 4. Column 6, the mean daily elevation of Lake Huron taken directly from Table 28. Column 7, the product of multiplying the mean daily elevation of Lake Huron by the number of days over which the observations extend. Column 8, the centers of gravity of the weighted discharges, or the weighted products of discharge, when divided by the sum of the multipliers involved in each portion of the series, and Column 9, similarly, the weighted centers of gravity of the position of Lake Huron.

Mr. Wilkerson: Q. I think you have explained already, Mr. Williams, but I wish you would tell us again why in Group 1. Column 1, Group 1, in the fourth column, where you have a multiplier of ten, why you put ten there.

A. Turn back to Table 29, and you will find that Group 1 covers a period of ten days, and we have weighted according to time.

We then find from Columns 8 and 9, subtracting the lower center of gravity of discharge from the upper, that a change of 15,820 cubic feet per second, corresponded to a change of

elevation, subtracting the lower center of gravity from the upper center of gravity in Column 9 of 0.507 feet. Whence the deduced increment of the St. Clair River is 31,203 cubic feet per second.

In Table 32 we start again with the data of Table 29, Exhibit 34, this time assuming that the change of St. Clair corresponding to a change of Huron has been such as is indicated by a comparison of the annual changes of the lakes from 1890 to 1910; or that a change of one foot in Lake Huron is accompanied by a change of 89 per cent. of one foot in Lake St. Clair, and that the effect of a rise of one foot in Lake St. Clair is as before to reduce the discharge of the St. Clair River 13,000 cubic feet.

Table 32 then corresponds to Table 30, in the previous computation. And it is perhaps interesting to note that in this instance Group 1 represents normal relations, there being no correction required to the position of Lake St. Clair.

Column 1, as in the previous table, gives the number of the group. Column 2, the change of the elevation of Huron from the mean. Column, 3, the observed change of elevation of Lake St. Clair from the mean. Column 4, the normal change of Lake St. Clair from the mean, as determined by multiplying the change of Lake Huron by .89.

Column 5, the difference between the normal position of Lake St. Clair, and the observed position. Column 6, the correction due to the change of St. Clair from its normal position, being the product of 13,000 by the difference indicated in Column 5. Column 7, the observed discharge, corresponding to Column 7 in Table 30, and taken directly from Table 28. And Column 8, the corrected discharge or the discharge which it is assumed would have existed, had Lake St. Clair been in its normal relation to Lake Huron, as determined by its mean relation from 1890 to 1910, and by the annual changes of elevation of the two lakes throughout the same period.

Table 33 then corresponds to Table 31, in which column 1 gives the numbers of the groups; column 2, the mean daily elevation of Lake St. Clair, Column 3, the corrected discharge as taken from Column 8 of Table 32. Column 4, the multiplier, being the number of days over which each group of observations extends. Column 5, the product of the multiplier by the discharge. Column 6, the mean daily elevation of Lake Huron. Column 7, the product of the multiplier by the elevation of Lake Huron, Column 8 the centers of gravity of the weighted

discharges and Column 9 the centers of gravity of the weighted elevations.

Subtracting the lower center of gravity of Column 8 from the upper, we find that the discharge was increased 14,638 cubic feet per second, for the change of elevation of Lake Huron indicated by the difference between the lower center of gravity and the upper center of gravity in Column 9, or 0.507 foot, which represents an increment of 28,872 cubic feet per second.

I now examine the gaugings of the St. Clair River made at Dry Dock Section, Section Gorge, during the years 1908, 1909 and 1910, as presented in Exhibits 22 and 23. These gaugings embrace 58 measurements at the Dry Dock Section, covering a range of Lake Huron elevation from 580.54 to 579.45; and 209 measurements at the Gorge Section, covering a range from 580.75 to 579.45, all of which have been combined.

In view of the testimony of complainant's witness Shenehon, file 6, page 44, or page 502 of the continuously paged letters, in which in answer to "Q. What do you say as to the precision of River Gauging done by the Lake Survey? A. I consider a discharge measurement, or rather a series of them, to have a precision of one per cent.," and in view of the further testimony of the same witness in file 6, page 49, or page 507 of the continuously paged record, in answer to the question: "Q. What do you think to be the precision of your observations as to sounding? A. That is well within one per cent. in all cases," it does not seem to me that it was necessary to separate the discharges at the Dry Dock Section, as taken in 1908, 1909 and 1910, from those at the Gorge Section taken during the same years by the same parties, who had already had the benefit of the previous experience to which the complainant's witness testified.

These observations have been examined in a manner similar to those of 1899, 1900, 1901 and 1902. The determination for the case of Lake St. Clair at a constant elevation during this latter period is given in Table 25, in which there are 47 groups ranging in number from two to seventeen observations, in which the elevation of Lake St. Clair was the same in each.

I may remark, during these later observations, Lake St. Clair does not appear to have been nearly so accommodating as it was during the previous period, where for weeks it remained conveniently at one elevation, but during this period it seems to change almost daily.

This Table 25 corresponds with Table 22 already described.

Mr. Adcock: What does that indicate?

A. It might indicate two things; one that he had a different—

Q. That is your last statement?

A. One, that we had a different kind of water, something approaching to molasses, or syrup during the observations of 1899 and 1910; and that during the later periods we had a more volatile liquid approaching perhaps to the ordinarily recognized water, or possibly to alcohol. Or, it may indicate that during the earlier period, the gauge reader slept at his watch at times, and failed to record the elevation that actually existed, and later, some days later, filled his note book with a record connected from his mind, in which he carried on the same elevation that he had last observed, until he happened to go to the gauge and take another one.

I think this is a fair commentary upon the general accuracy of the readings that have been introduced in this case, during particularly the earlier periods covered by the testimony, and it shows one of the great sources of error, which no refinements of mathematics or assumptions of the investigator can possibly eliminate.

Columns 3-4, 5-6 and 7-8, give the centers of gravity of the elevations of Huron and the discharges for the respective periods.

Column 9 gives the deduced equation, and Column 10 the increment, whose arithmetic mean would seem to be 34,510. When these values of the increment are weighted in proportion to the number of observations included in each group, as shown in the first half of Table 27, of Exhibit 34, in a manner similar to that described with reference to Table 24 of the same exhibit, the increment of the St. Clair River due to a change of one foot in Lake Huron, as indicated by the combined gaugings at the Dry Dock and Gorge Section of the observations of 1908 to 1910, inclusive, is found to be 35,797 cubic feet per second, or within 400 cubic feet per second of the value similarly deduced from the observations from 1899 to 1902 by a similar process of investigation.

Table 26 presents the increments due to changes of Lake St. Clair, when Lake Huron was at a constant elevation, or at the same elevation, and corresponds to Table 23 of Exhibit 34 previously described, and embraced forty groups of from two to eleven observations; the number of observations in each group being indicated in Column 1, Table 26.

Column 2 gives the elevation of Lake Huron. Columns 3-4, 5-6, 7-8, give the respective centers of gravity for the elevation of Lake St. Clair and for the discharge.

Column 9 gives the derived equation and Column 10 presents the individual increments, whose arithmetical mean is minus 12,230 cubic feet. And when these increments are weighted by the number of observations in each group as presented in the right-hand half of Table 27 of Exhibit 34, they being weighted in proportion to the number of observations in each group, the weighted mean effect of the rise of one foot in Lake St. Clair upon the discharge of the St. Clair River, other things remaining unchanged, is found to be eleven thousand eight hundred and seventeen cubic feet per second, or about 900 cubic feet per second less than that in the previous computation.

If we now apply to these computations the ratios stated by complainant's witness of the rise in Lake St. Clair to the rise in Huron, namely, that when Lake Huron rises one foot, Lake St. Clair rises two-thirds of a foot, we have as the net increment of the St. Clair River, 35,797 minus two-thirds times 11,817, equals 27,919 cubic feet per second.

If we apply the ratio for changes of St. Clair to changes of Lake Huron, as derived from the annual changes or from the mean annual elevations from 1890 to 1910, we have as the net increment 35,797 minus .89 times eleven thousand eight hundred and seventeen (11,817), equals 25,280 cubic feet per second.

In Table 34 of Exhibit 34, I have examined the observations of 1908 to 1910, at the Dry Dock and Gorge Sections, of the St. Clair River, by a method similar to that presented with reference to the earlier observations in Table 28, in which case it has been possible to select seven groups of observations when for considerable periods the surfaces of Lake St. Clair and Lake Huron showed moderate divergence from their mean position during the periods selected.

These observations are arranged in Table 34 in a manner entirely similar to that adopted in Table 28, with reference to the preceding observations.

Column 1 gives the number of the group, the numbering having been continued from that of the previous table.

Column 2 gives the dates of the observations indicated. Column 3 gives the mean daily elevation of Lake Huron, Column 4 gives the mean daily elevation of Lake St. Clair. The observed elevations of Lake Huron and Lake St. Clair have been omitted from this table.

Column 5 gives the dates of the discharge measurements, and it appears that in this case several measurements were made in a single day, frequently as many as five and in one

case at least six. Column 6 gives the observed discharge of the several measurements, and the mean discharge for the period. The mean elevations of Lakes Huron and St. Clair are given in Columns 3 and 4, in addition to the daily elevations.

The discharges observed as presented in the sixth column have been weighted by the time interval which they represent, which in this table is usually fractional, on account of there generally having been more than one observation in a day, and the last column of the table gives the weighted discharge, said discharge being weighted in proportion to the time covered between it, and the intermediate point between it and the next. The last column also gives the mean weighted discharge for the groups.

On Table 35 of Exhibit 34 is shown the information corresponding to that previously presented in Table 29 of the same exhibit relative to the first service of gagings.

In the first column is presented the number of the gagings in each group, which is seen to range from ten to fifty-five. The second column gives the number of the group, and the third the number of days in the group, which is seen to range from five to twenty. The fourth column gives the dates covered by the period. Column 5 gives the observed mean daily elevation of Lake Huron during the period of gagings, and Column 6 the change from the mean daily elevation of Huron, the mean elevation of Lake Huron from 1890 to 1910 for the open season, of 580.70, being taken as the mean position, and for Lake St. Clair the mean elevation during the open season, of 575.36, for the period from 1890 to 1910, being taken as the mean position.

The seventh column gives the mean daily elevation of Lake St. Clair, and the eighth column the change in the elevation of Lake St. Clair from its mean position of 575.36.

Table 26, which corresponds to Table 30 previously described, gives first, in the first column the number of the group; in the second column the observed change of Lake Huron from the mean as derived from Table 35. Column 3, the observed change of Lake St. Clair from the mean as derived from the same table, Table 35. Column 4, the assumed normal change of Lake St. Clair from its mean position, being the change of Huron multiplied by 66 2/3 per cent. in accordance with the testimony of the complainant's witness. Column 5, the difference between the observed change from mean of Lake St. Clair and the computed normal change from the mean position.

Column 6 then gives the correction due to the position of St. Clair, being the difference in Column 5 multiplied by the previously computed increment of the effect of Lake St. Clair as shown in Table 27, which is there given as minus 11,817; but has been taken for our computations as minus 12,000 cubic feet per second.

It is unnecessary, I assume, to call attention to the fact that any increase in the back water effect of Lake St. Clair in this computation is not to the advantage of the defendant; or, perhaps, is not to the prejudice of the complainant.

Column 7 gives the observed discharge as obtained from Table 24 and Column 8 the discharge corrected for Lake St. Clair in its assumed normal position in reference to Lake Huron by the addition, with its proper sign, of the correction in Column 6 to the observed discharge in Column 7.

Table 37 corresponds to Table 31. The first column gives the number of the group. The second column the mean daily elevation of Lake St. Clair; the third, the corrected discharge; the fourth, the multiplier for weighted observation, being the number of days in each period; Column 5, the product of the discharge by the number of days; the sixth column, the mean daily elevation of Lake Huron; Column 7, the product of the mean daily elevation of Lake Huron by the number of days; Column 8, the weighted centers of gravity of the discharge; Column 9, the weighted centers of gravity of the elevations of Lake Huron. When it appears, by subtracting the lower center of gravity of the discharge from the upper center of gravity as shown in Column 8, there is a difference of 11,389 cubic feet per second, which occurs during the range indicated by the difference between the upper center of gravity in Column 9 and the lower center of gravity in the same column, or .268 of a foot; and gives, therefore, an increment of 30,948, or less than five hundred cubic feet per second difference from the increment obtained in Table 31 from the observations of 1899 to 1902, by a similar process of examination.

Table 38 corresponds to Table 32, in that, instead of using the ratio for change of Lake St. Clair with reference to Lake Huron, testified to by the complainant, there has been used the ratio determined by the annual comparison of the elevations of the two lakes from 1890 to 1910. Whence it was shown that the change of Lake St. Clair had been 89 per cent. of the change of Huron, instead of 66 2/3 per cent. as testified to by the complainant's witness.

Column 1 gives the numbers of the group; Column 2, the observed change of Lake Huron from its mean position as

previously defined; Column 3, the observed change of St. Clair from its mean position; Column 4, the change of St. Clair from its mean position, assuming that change to be 89 per cent. of the Huron change. Column 5, the difference between the observed change and the computed normal change, the normal change being 89 per cent. of that of the change in Huron. Column 6, the corrections to the discharge due to the variation of Lake St. Clair from its normal position, being the increment, minus 12,000 cubic feet per second, for the effect of one foot rise on Lake St. Clair upon the discharge of the St. Clair River, multiplied by the difference in Column 5.

Column 7 gives the observed discharge for the periods in question, which has been taken from Table 34, and Column 8 presents the discharge corrected for St. Clair in its normal position.

Table 39 corresponds to Table 33, and Column 1 presents the numbers of the group; Column 2 the mean daily elevation of Lake St. Clair; Column 3 the corrected discharge; Column 4 the multiplier, being the number of days included in each period; Column 5 the product of the discharge by the multiplier; Column 6 the mean daily elevation of Lake Huron; Column 7 the product of the mean daily elevation of Lake Huron multiplied by the multiplier in Column 4; Column 8 the centers of gravity of the weighted discharges; Column 9 the centers of gravity of the weighted elevations of Lake Huron. Whence it is seen that, subtracting the lower center of gravity for Column 8 from the upper center of gravity in the same column, there is a change of 10,417 cubic feet per second, and the change of elevation corresponding to this change, is found by subtracting the lower center of gravity in Column 9 from the upper center of gravity in the same column, to be .0368 foot. And the increment therefore derived is shown at the foot of Table 39, 28,307 cubic feet per second, which is within 575 cubic feet per second of the increment previously derived by a similar process of reasoning from the observations of 1899 to 1902, inclusive, as shown on Table 33 of Exhibit 34.

The shorter range, both in time and stage for this last series, and the possible criticism that the combination of observations at two sections may involve errors in the derived increment, leads me to consider these last computations as in the nature of checks upon the accuracy of the work of 1899 to 1902, and upon the reasonableness of the increment derived from those gagings, as presented in Table 33 of 28,872 cubic

feet per second, as being the most probable increment of the St. Clair River that has yet been derived. And as in future investigations of the problems involved, it will be desirable to be able to use the increment of Lake Huron as separate from the increment of Lake St. Clair, we proceed to obtain the increment for one foot change of Lake Huron, other conditions remaining unchanged, as follows: The net increment for the river as just obtained—28,872 cubic feet per second—when increased by the effect of back water from Lake St. Clair, due to one foot rise of Huron, or by .89 times 13,000, gives as the increment of the St. Clair River due to a rise of one foot in Lake Huron, assuming that Lake St. Clair does not change its position, 40,442 cubic feet per second.

Table 40 of Exhibit 34 gives at the top, on the left-hand side, the equation of discharge of the St. Clair River as derived by the investigations heretofore, and is: The discharge of the St. Clair River equals (Huron elevation minus 580.70), times 40,442 minus (St. Clair elevations minus 575.36), times 13,000 plus 197,610, being in cubic feet per second.

Column 1 in this table gives the year in question and also underneath the average discharge of the river for that year, as computed by the equation at the top of the page.

The second column gives the months; the third column gives the mean elevation of Huron for the months; the third column gives the rise or fall of Huron above or below its mean position; rises being designated as plus, and falls as minus. Column 5 gives the increased or decreased discharge due to the position of Huron. Column 6 gives the mean elevation of Lake St. Clair. Column 7 gives the rise or fall of Lake St. Clair above or below its mean position. Column 7 gives the decrease due to the position of Lake St. Clair. Column 8 gives the net increase of discharge over the normal discharge, or the discharge at mean position of 197,610. And the last column gives the monthly discharge as computed by the formula.

This table covers the years from 1900 to 1907, inclusive; and at the bottom of the second page of the said table is given the mean discharge from 1900 to 1904, as 191,023 cubic feet per second, and at the bottom of the third page of the table the mean discharge from 1900 to 1907 as 197,633 cubic feet per second.

The mean discharge by the complainant's equation, as shown on Table 20 of Exhibit 34, for the period from 1900 to 1904, is 188,787 cubic feet per second; and from 1900 to 1907, inclusive, as shown on the same table, is 193,528; the

discharges computed by the defendant's equation being for the shorter period, about 2,300 cubic feet, and for the longer period, about 4,000 cubic feet per second, greater than those shown by the complainant.

Adjourned to Monday, March 24, 1913, at 10:00 a. m.

Monday, March 24, 1913, 10:00 a. m.

Met pursuant to adjournment.

Present same as before.

GARDNER S. WILLIAMS resumed the stand and testified further as follows:

Mr. Adcock: Have you made any calculations from, or examination of the records of the discharge measurements of the St. Lawrence River; and have you made any comparison between the records of such discharge measurements and those of any other of the rivers mentioned?

A. I have.

Q. Will you state the results of such examination and comparison?

A. The increment of the St. Lawrence River is given on Complainant's Exhibit 2 as 28,870 cubic feet per second for one foot change of stage of the St. Lawrence River referred to the Ogdensburg gage. If this quantity be computed mathematically on the assumption that the discharge curve is a straight line, and all observations are given equal weight, the value of the increment is found to be 29,230 cubic feet per second.

When, however, the observations are grouped chronologically, as is done in Table 41 of Exhibit 34 in which the observations have been grouped into six groups, varying from four to 23 observations in a group, and the mean discharges, and mean lake elevations of each group have been weighted according to the number of days covered by each discharge, in a manner similar to that which has already been explained with reference to the observations on the St. Clair River, the results are grouped in Table 42 in which the first column presents the number of gagings; the second, the number of the group; the third column, the number of days covered by each group; the fourth column, the mean daily stage at Ogdensburg; the fifth column ,the multiplier by which stage and discharge are multiplied, being the number of days included in

the group. Column 6 presents the product of the elevation by the multiplier; Column 7, the centers of gravity of the elevations; Column 8, the discharges as observed; Column 9, the multiplier, being again the number of days in each group; Column 10, the product of the discharge by the multiplier; Column 11, the centers of gravity of the discharge.

Whence, taking the lower center of gravity of Column 7 from the upper center of gravity of the same column, we have a range of 1.029 foot, on the gage at Ogdensburg, representing a change of discharge determined by subtracting the lower center of gravity in Column 11 from the upper center of gravity in the same column, giving 32,844 cubic feet per second.

Whence, dividing the change in discharge by the change in elevation, we get the increment as 31,918 cubic feet per second for one foot change in stage of the elevation of the St. Lawrence River at Ogdensburg.

The fluctuation of the Ogdensburg gage, that is, its variation in rise and fall, is approximately 95 per cent. of that of the Oswego gage, which is at the foot of the lake itself; the Ogdensburg gage being about 60 miles down the St. Lawrence River, which is, however, through this region wide and deep; and may be looked upon as practically an arm of the lake.

It, therefore, follows in view of the fact that the increment varies inversely as the fluctuation, that the increment when referred to the Oswego gage would be approximately .95 of 31,918 or 30,322 cubic feet per second.

For the period from 1900 to 1907, inclusive, the average discharge of the St. Lawrence River, by the complainant's equation, has been computed in Table 43, the elevation of the Ogdensburg gage being taken from the report of the International Waterways Commission on the regulation of Lake Erie, dated 1910, being presented in Table 14, on page 97 of the said report. From this table as shown on the same, the mean discharge from 1900 to 1907 inclusive, was 247,762 cubic feet per second. For the same period the discharge of the Niagara has been computed and is presented in Table 11 for the Bridge Section, and in Table 12 for the Open Section, the discharges being computed by the complainant's equation, using the height of the Buffalo gage as indicated in the Report of the International Waterways Commission on the Regulation of Lake Erie for 1910, and shown in Table 11, page 94 of the said report.

The average discharge of the Niagara River by the complainant's equation for the Bridge Section as derived from

the observations at the Bridge Section, is 201,436 cubic feet per second. The average discharge for the Niagara River, as derived from the complainant's equation from the Open Section, is 198,708 cubic feet per second, showing a difference of about 2,700 cubic feet per second.

For the purposes of the present investgation, that is, of the relations between the discharges and increments of the several rivers, as shown by the complainant's evidence, a mean of the average discharges of the Niagara River at two sections has been used, which is 200,072 cubic feet per second. For the same years—1900 to 1907, inclusive—Table 20 gives the discharge of the St. Clair River computed by the complainant's equation; the reference being to the gage at Harbor Beach, which is shown upon Exhibit 26. The mean discharge is found to be, as shown on Table 20, 193,528 cubic feet per second. Comparing the figures for the mean discharge of the St. Lawrence with those for the mean discharge of the Niagara, it appears that approximately 81 per cent. of the discharge of Lake Ontario came from Lake Erie, or 200,072 divided by 247,762 equals 0.81, nearly.

From 1860 to 1903, a period previous to the construction of the Gut Dam, so-called, which according to the complainant's testimony in file 6 at page 21 of the original record, being page 479 of the continuously paged record, disturbed the relation causing a rise of Lake Ontario due to a reduction of the discharge of the St. Lawrence River on account of obstruction of one of its channels. The fluctuations of Lake Ontario or the annual changes of elevation, or more properly the changes of mean annual elevation, when compared with those of Lake Erie as shown on Table 44, are found to be 44.6 per cent. greater than those of Lake Erie. Remembering the principle that the variation of elevation of the water in a reservoir is inversely as the magnitude of the increment, if the same quantity of water were delivered through both the Niagara and the St. Lawrence Rivers, we would expect the increment of the Niagara to be 44.6 per cent. greater than the increment of the St. Lawrence. But in view of the fact that only 81 per cent. of the water of the St. Lawrence, according to the complainant's evidence, comes from the Niagara River, it is to be expected that approximately 81 per cent. of the fluctuation of Lake Ontario is due to the water received from Niagara, and therefore it would be expected that the changes in Ontario corresponding to or comparable with the changes in Erie, would be 81 per cent. of 144.6 per cent., or 117 per cent. of the changes in Erie.

If, then, the increments are inversely proportional to the changes of elevation, and if the increment of the St. Lawrence River is 30,322 cubic feet per second, as deduced from the chronological groupings of the complainant's gagings on Table 42, when reduced to the Oswego gage, as already explained, it is to be expected that the increment of the Niagara must be 1.17 times as great, or about 35,480 cubic feet per second.

Proceeding now to a similar comparison of the fluctuations of Lake Erie and Lake Huron, we find, first, comparing the average discharges of the St. Clair and Niagara Rivers, that according to the testimony of complainant's witnesses, about 96.7 per cent. of the water discharged from Niagara comes from the St. Clair River, or that the quantity discharged by the St. Clair River into Lake Erie is about 96.7 per cent. of that purporting to be discharged by the Niagara River; that is to say, 193,528 cubic feet per second, the average discharge of the St. Clair River divided by 200,072 cubic feet per second, the average discharge of the Niagara, gives approximately 0.967.

Q. The discharge of the Niagara referred to, according to the discharge measurements?

A. Yes, the discharge of the Niagara being the mean of the discharges computed from the complainant's equations for the Bridge and Open Sections on the Niagara River, for the period from 1900 to 1907, inclusive.

For the period from 1860 to 1889, inclusive, the changes of mean annual stage of Lake Erie, when compared with the same for Lake Huron, as shown in Table 21 of Exhibit 34, the right-hand portion of the page shows that the changes of mean annual stage of Lake Erie have been about 75 per cent. of the changes of mean annual stage of Lake Huron for the period in question. However, as already pointed out, an examination of the relations of the lake stages indicates that about 1890, or 1889, there was a marked change of some sort in the conditions affecting lake stage, and since 1890, that is from 1891 to 1910, as shown in the right-hand bottom portion of Table 21, the changes in Lake Erie have been 85.5 per cent. of those in Lake Huron.

The method of derivation of this information, as shown on Tables 21 and 44, has been to plot the simultaneous mean annual elevations of the lakes in question and to derive the equation for the straight line which most nearly fits those elevations, by the center of gravity method. So that we have in Column 9 of Table 21, the three centers of gravity for the ele-

vations of Lake Huron; and in Column 11, the three centers of gravity for the elevation of Lake Erie. Subtracting the bottom from the top center of gravity in each case, and dividing the average change of elevation of Erie by the average change of elevation of Huron, we get the percentages in the lower right-hand corner of Table 21; and similarly, with reference to Ontario and Erie in Table 44, Column 4 gives the centers of gravity of the elevations of Lake Erie, and Column 6 the centers of gravity of the elevations of Ontario, and dividing the difference of the top and bottom centers of gravity for Ontario by the difference for Erie, we get 144.6 per cent. as indicated in the lower right-hand corner of the table, for the relation of the changes of mean annual elevation of Lake Ontario and the similar changes of Lake Erie.

In Table 21, it will be noticed that the year 1890 has been omitted. This has been done because apparently there were greater changes in conditions during the year 1890, that seeming to be a part of a transition period from the conditions of the period of the previous 30 years to the conditions of the following 20 years, and the year in which changes seemed to be taking place most prominently.

As the discharge observations submitted in the complainant's testimony have all been taken since 1891, the relations for the later period are utilized, and it is to be expected that inasmuch as 96.7 per cent. of the water discharged by the Niagara River, is represented by the inflow from the St. Clair River, that 96.7 per cent. of the fluctuation of Lake Erie would be due to that supply, approximately, or that the fluctuations of Lake Erie which correspond to the fluctuations of Lake Huron would be as 0.967 times 0.86 equals 0.83. And referring again to the principle that the fluctuations are inversely as the increment, it would be expected that since the fluctuations of Huron are greater than the fluctuations of Erie, that the increment of the St. Clair River should be 83 per cent. of the increment of the Niagara River. And taking the value of the increment of the Niagara River, which is deduced from the St. Lawrence, of 35,480 multiplying by 0.83, we get 29,450 cubic feet per second as the increment of the St. Clair River, assuming the increment of the St. Lawrence to be correctly determined and deriving it therefrom by means of the fluctuations of the intervening lakes, and Lake Huron.

If instead of the discharges from the complainant's equation, we use those of the St. Lawrence and St. Clair Rivers

from the equations submitted by the defendant, the result is as follows:

By Table 43-A, defendant's equation for the St. Lawrence, the mean discharge of the St. Lawrence River for the period from 1900 to 1907 is 248,721 cubic feet per second. Using the Niagara discharge as before, 200,072 cubic feet per second, as derived from the complainant's equations, it represents 80.2 per cent. of the flow of the St. Lawrence; and combining this with the relation of fluctuations, the ratio of the increments of the St. Lawrence and Niagara become 0.802 times 1.446 equals 1.16 and the increment of the Niagara then becomes 1.16 multiplied by 30,322 equals 35,200 cubic feet per second, or approximately the same as before.

The mean discharge of the St. Clair River from 1900 to 1907, based upon the equations of the defendants is 197,633 cubic feet per second, which is 98.8 per cent. of the Niagara discharge. And we would then expect the St. Clair increment to be, taking into consideration the percentage of discharge coming from the St. Clair River and the ratio of the fluctuations, 0.988 times 0.85 equals 0.84, multiplied by 35,200, the increment of the Niagara as just deduced, equals 29,600 cubic feet per second.

As will be shown later, the increment of the St. Clair River appears to have been increasing during the period from 1891 to 1907, and as the fluctuation relation is deduced for the average condition of the period from 1891 to 1910, it follows that at the present time the Erie fluctuations will be more nearly those of Huron, and the increment of the St. Clair therefore somewhat larger than for the average condition of the period. And hence it is concluded that the value which is derived of 29,600 cubic feet per second for the increment of the St. Clair River is somewhat low.

Comparing this value of 29,600 cubic feet per second for the St. Clair River derived from the St. Lawrence gaging, and the fluctuations of the intervening lakes and Lake Huron, with that of 28,872 cubic feet per second, as deduced from Table 33 from an examination of the measurements of the complainant by periods of consecutive stage, the coincidence of the two values, the one being derived from the St. Clair gagings, without reference to any others, and the other being derived from the St. Lawrence gagings, using only the St. Clair gagings to determine the quantity of water flowing, seems to me to be a remarkable coincidence if based on any but a rational procedure.

In this connection, attention is to be called to the fact that this computation gives an increment for the Niagara River entirely out of harmony with anything presented in the testimony of the complainant. The increment based upon the discharge at the International Bridge Section, as presented by the complainant, is 21,900 cubic feet per second, and as based upon the observations at the Open Section, as presented by the complainant, is 21,640 cubic feet per second; but by this comparison which, starting from the St. Lawrence and concerning which work in his testimony the complainant has raised no suspicion, and checking by the increment derived from the St. Clair, a similar process of derivation being used on the two rivers, and all the intrinsic evidence of the observations indicating that the discharges as measured on the St. Lawrence and the St. Clair are the more accurate of those presented, an increment is obtained for the Niagara of over 35,000 cubic feet per second, or something over 60 per cent. greater than the increment presented by the complainant.

I would in this connection refer to the testimony of complainant's witness Shenehon, folio 7, at pages 50-51 of the original record, being pages 598 and 599 of the continuously paged record, where the witness referring to the fact as testified to by him that the variations of Lake Erie are 70 per cent. approximately of those of Lake Huron is asked this question: "Q. Why isn't there just as much of an effect in Lake Erie as there is in Lakes Huron and Michigan? Why is it 70 per cent. or any other per cent.? A. It is 70 per cent. because the observations show that the thing is running that way." "Q. But do you have any reason for it except that you have noticed that it was a fact? A. I have stated that the reason, I think, the controlling reason, is the fact that the increment in the St. Clair River is really smaller than the increment in the Niagara River. Let me make that clear: In the case of small pools where the reservoir effect does not enter so largely, and we can see the thing very much more clearly, if we know the increments of two pools, as for instance the Whirlpool, and the pool in the Niagara River above the Rapids, above the cataract; if we know that the increments are in the ratio of 2.50 to 0.56, we know very well that the fluctuations would bear the inverse ratio. It is not entirely certain that when you take large reservoirs like Lakes Michigan, Huron and Erie, that you can—rather, it is very certain that you cannot—argue with the same certainty that you would in the case of these smaller pools. The local supply, local run-off, local

evaporation, those elements are likely to enter in, and I do not want to state, on the face of that, clearly, that I know the increment in the St. Clair River is smaller than it is in the Niagara River; but I think it is a clear proposition."

It therefore appears that the deductions of the previously described investigation as to the relations between the increments of the St. Lawrence, Niagara and St. Clair, are corroborated by the inner consciousness of the complainant's witness, although contradicted by the physical facts of the complainant's gagings.

Mr. Wilkerson: I will move to strike that out as argumentative.

The Witness: The Niagara gagings, when referred to the mean daily gage height on the Buffalo Gage, and treated by chronological grouping as shown in Table 45, give an increment of 27,336. The construction of this table is exactly similar to that of the table for the St. Lawrence, and the two tables that were similarly constructed for the St. Clair. The table of preliminary groups has not been included in the exhibit, but will be furnished to the complainants for inspection if they so desire.

The Buffalo Gage is situated at the east end of the lake near its outlet, and is undoubtedly the gage which controls most nearly the discharge of the river. It is not the gage, however, by which the mean elevation of the lake is established, as the record of the Cleveland Gage has been accepted for that purpose, I think for two reasons; one, that there was some question as to the early accuracy of the elevation of the Buffalo Gage, and the other, that the Cleveland Gage being situated near the middle of the lake, is less affected by the fluctuations of surface due to wind than would be a gage at either end.

If the elevation of Lake Erie be established by the mean of the gage at Buffalo at the east end of the lake and the gage at Amherstburg, at the foot of the Detroit River at the west end of the lake shown on Table 46, the increment becomes 28,359 cubic feet per second. And if the Cleveland Gage be used, as shown on Table 47, the increment becomes 32,060 cubic feet per second.

Lake Erie is noted for its violent fluctuations, due particularly to wind effects, which on account of the shallowness of the lake preventing the free flow of the return currents, causes the water to pile up at one end or the other as the direction of the wind may be; and there exists a

continual surging from end to end due to these wind effects and barometric changes. This contributes largely to the difficulty of accurate measurement of the discharge from this lake. The swiftness of the current at the gaging station, and the always accompanying pulsations of swift running water, together with the depth of the measuring section, all introduce elements affecting the absolute accuracy of any current meter gaging. And while at the Bridge Section the possibility of working from a rigid platform afforded a noticeable advantage over any of the other sites, this was to a large extent counteracted by the irregular currents set up as the water passed the piers, its flow being disturbed and eddy motions created, which may lead to very serious errors in current meter work.

Furthermore, the fact that there is a fall of about five feet between the lake and the gaging section tends to obscure to a considerable extent the effects of changes in the lake, so that bearing in mind that when the discharge from a reservoir whose surface is fluctuating is measured, while the discharge itself may be accurately measured, the increment derived from those discharges will necessarily be too small by reason of the fact that the discharge does not increase or decrease as rapidly as the elevation of the lake surface changes.

Considering all these elements as affecting the gagings at the Niagara River, as well as the evidence of the comparisons of those gagings, already discussed and presented in Tables 9 and 10 of Exhibit 34, it is not surprising to me to find that the results of these observations do not harmonize with those of the other two rivers; and it is my belief that the value of the increment, 35,000 cubic feet per second, derived from the St. Lawrence and St. Clair discharges and the lake stage relations covering a long period of years, is more nearly correct than that deduced from the Niagara gagings, which covered only a brief period of time, and were subject to many very difficult conditions.

At this time I want to say that my criticism of the Niagara work is a criticism of the conditions and not of the work which was done, for it is my belief that there is nowhere on record a more painstaking example of experimental work in the nature of stream gaging, than that which is exhibited in the record of the Niagara gagings.

In this connection, I would refer to the Report of the International Waterways Commission, being Exhibit 33, Report of the International Waterways Commission on the Regula-

tion of Lake Erie, 1910, where it is stated in paragraph 147, page 81:

"Artificial storage of water in Lake Superior between December, 1888, and December, 1907, inclusive, by the placing of obstructions in the upper St. Mary's River, has had the effect of raising the mean stage of Lake Superior by about 0.87 foot in 1904 and of lowering Lakes Michigan, Huron, Lake Erie and Lake Ontario by the maximum of 0.15, 0.12, 0.10 foot respectvely."

What I would call particular attention to here is the fact that the lowering of Lake Erie is placed intermediate between that of Lake Ontario and Lake St. Clair, and indicating a ratio between the increments of the St. Clair River and the Niagara of 15 divided by 12 or 1.25 per cent. If this relation were correct, and the increment of the St. Clair River be as assumed and computed by the defendant, 28,872 cubic feet per second, the increment of the Niagara would be a little over 36,000 cubic feet per second.

Mr. Adcock: Have you made any examination of the complainant's discharge equations with reference to the physical conditions of the Great Lakes?

A. I have.

Q. Will you state the result of such examination and the different steps by which you reach the result which you claim to be the correct result; and give the basis for your conclusions?

A. The complainant's discharge equations, and the results to be derived from them have been examined with a view to testing the accuracy of the experimental conclusions by applying the results to the physical conditions to which they are related on the Great Lakes. And for the purposes of such a comparison, the hydraulics and hydrography and hydrology of the Great Lakes system have been examined in the light of the complainant's discharge equations.

The preliminary examinations embraced a comparison of the discharges from 1900 to 1907, inclusive, when, as before stated, by the complainant's equation as presented in Table 43, the mean discharge of the St. Lawrence River was 247,762 cubic feet per second. The total land drainage tributary to the St. Lawrence River, being the land drainage areas of all the Great Lakes, based upon the Report of the International Waterways Commission on the Regulation of Lake Erie of 1910 and presented there, or derivable from the table presented on page 9 and designated as Table "A," by subtract-

ing the area of the lake surface from the drainage area including lake surface, given in the said table, is found to be 192,600 square miles.

Mr. Wilkerson: Let me make a statement, Mr. Commissioner, about this report of the International Waterways Commission on the Regulation of Lake Erie for 1910. It is understood that this document, as it is referred to in connection with the testimony of this witness and other witnesses, is to be treated in evidence to the extent that either side, in either the direct examination of the witness or the cross-examination of the witnesses, may refer to such portions of it as may be deemed pertinent to the inquiry; that being for the purpose of avoiding the necessity of copying the entire document into the record.

Mr. Adcock: And offer in evidence such portions as you may refer to.

Mr. Wilkerson: Each side will indicate such portions as they want. It may be before we get through with the discussion that the whole document will have to go in.

The Witness: The discharge of the St. Lawrence River as given above 247,762 cubic feet per second is equivalent to a run-off from this land drainage area of 192,600 square miles of an average of 1.28 cubic feet per second per square mile.

If we take the total drainage area, including the lake surfaces tributary to the St. Lawrence River, which is, as shown in the report of the International Waterways Commission on the Regulation of Lake Erie, 1910, in Table "A" on page 9, 287,688 square miles, the average run-off per square mile represented by the discharge of the St. Lawrence River for this entire drainage area is 0.861 cubic feet per second.

Taking for the Niagara the mean discharge of the Open and Bridge Section equations for the period from 1900 to 1907 inclusive, 200,072 cubic feet per second, and from the table on page 9 of the Report of the International Waterways Commission, the land drainage tributary to the Niagara River derived by a simple process of subtraction as 166,863 square miles, the above discharge of the Niagara is equivalent to a run-off per square mile of 1.2 cubic feet per second from this land drainage.

The total drainage area including the lake surfaces tributary to the Niagara River, from the aforesaid authority, is 254,708 square miles, and the discharge of the Niagara River as presented by the equations of the complainant therefore

represents a run-off of 0.785 cubic feet per second per square mile for the total drainage area above it.

The discharge of the St. Clair River from 1900 to 1907, as computed from the complainant's equation in Table XX, is 193,528 cubic feet per second; the land drainage tributary to the St. Clair River, as shown in the table of the Report of the International Waterways Commission, above referred to, is 136,567 square miles, and the above discharge is equivalent to an average run-off per square mile from this land drainage of 1.42 cubic feet per second.

The total drainage area of the St. Clair River is 213,941 square miles, and the average run-off from this total drainage, as represented by the above computed discharge of the St. Clair River from the complainant's equation is 0.905 cubic feet per second per square mile.

The St. Mary's River has not been introduced into this case as yet, but as the conditions of run-off and evaporation may be appreciably different upon Lake Superior from those on Lakes Huron and Michigan, for the sake of following this process of investigation to the end, the average discharge of the St. Mary's River from 1900 to 1907 has been taken from the Report of the International Waterways Commission upon the Regulation of Lake Erie, the same being shown on page 101, being marked Exhibit 33-F. This average discharge from 1900 to 1907 of the St. Mary's River is found to be 78,200 cubic feet per second. The land drainage tributary thereto, from the report of the International Waterways Commission, is 44,074 square miles, and the above discharge is equivalent to an average run-off of 1.78 cubic feet per second per square mile for the land drainage.

The total drainage tributary to the St. Mary's River is 76,134 square miles, which gives as the equivalent of the above discharge, an average run-off per square mile of 1.028 cubic feet per second, from the entire drainage area.

It will be noticed in passing that the run-offs per square mile show a progressive increase both for the land drainage and the total drainage, from the St. Lawrence to the St. Mary's, with the exception of Niagara, which shows a reduction of average run-off from its drainage area.

We next consider the evidence of local discharge, and by local discharge we mean that portion of the river which comes from the drainage area between it and the river next above. The local discharge of the St. Lawrence would then be represented by the difference in the discharge of the St. Law-

rence and Niagara River; and the local discharge of the Niagara would be represented by the difference between the Niagara and the St. Clair; and the local discharge of the St. Clair would be represented by the difference between the discharge of the St. Clair and the St. Mary's Rivers. And in the case of the St. Mary's, the total discharge and the local discharge would coincide. Subtracting from the discharge of the St. Lawrence, the discharge of the Niagara above, as previously computed from the complainant's equations, the former being 247,762 cubic feet per second, and the latter 200,072 cubic feet per second, the difference is 47,690 cubic feet per second, which represents the discharge due to the drainage area of Lake Ontario, and so much of the Niagara River as is below the gaging station at which the discharge of the Niagara River was measured.

Similarly, subtracting from the discharge of the Niagara River 200,072 cubic feet per second, the discharge of the St. Clair River, 193,528 cubic feet per second, there remains as the discharge from the drainage area of Lake Erie and St. Clair, and so much of the Detroit and St. Clair Rivers as are below the gaging station on the St. Clair River, 6,544 cubic feet per second.

Subtracting from the discharge of the St. Clair River 193,528 cubic feet per second, the discharge of the St. Mary's River as derived from the Report of the International Waterways Commission 78,200 cubic feet per second, it leaves as the discharge from the drainage areas of Lakes Michigan-Huron, and so much of the St. Mary's River as is below the point of gaging on the said river, 115,326 cubic feet per second.

Referring again to Table "A," page 9, of the Report of the International Waterways Commission upon the Regulation of Lake Erie for 1910, the land drainage tributary to Lake Ontario and so much of the Niagara River as lies below the point of gaging of the Niagara, is 25,737 square miles. The excess of run-off of the St. Lawrence River over that of the Niagara, 47,690 cubic feet per second, then is equivalent to a run-off from this land drainage, of 1.85 cubic feet per second per square mile. Similarly the land drainage of Lakes Erie and Ontario, and so much of the Detroit and St. Clair Rivers as lie below the point of gaging on the St. Clair River, is shown by the above authority to be 30,296 square miles, and the excess of discharge of the Niagara River over that of the St. Clair River 6,544 cubic feet per second is equivalent to a run-off from this land area of 0.216 cubic feet per second per

square mile, or about 1/9 of the amount that runs off, apparently, from the watershed of Lake Ontario.

From the Report of the International Waterways Commission it appears that the land drainage tributary to the St. Clair River, on Lakes Michigan and Huron and so much of the St. Mary's River as lies below the gaging station for that river, is 92,493 square miles, and the difference in discharge between the St. Clair and St. Mary's Rivers 115,328 cubic feet per second is equivalent to a run-off from this land drainage of 1.25 cubic feet per second per square mile, or about six times as great as that appearing from the Lake Erie drainage, and about 2/3 as great as that appearing from the St. Lawrence drainage.

If instead of taking the land surfaces only upon these drainage areas we take both the land and water surfaces which are given directly in Tables "A," page 9 of the Report of the International Waterways Commission on the Regulation of Lake Erie for 1910, we find that the total drainage tributary to the St. Lawrence River below the point of gaging of the Niagara River to be 32,980 square miles, the difference between the St. Lawrence and Niagara discharges, 47,690 cubic feet per second, for this area is equivalent to an average run-off of 1.45 cubic feet per second per square mile, for the Ontario drainage. The total drainage including lake surface tributary to the Niagara River between the point of gaging on that river and the point of gaging on the St. Clair River is obtained from the aforesaid report to be 40,767 square miles, and the difference of the Niagara and St. Clair discharges, 6,544 cubic feet per second is equivalent to an average run-off upon the drainage area of Lake Erie and Lake St. Clair and so much of the Detroit and St. Clair Rivers as are below the point of gaging of the St. Clair River of 0.16 cubic feet per second per square mile, or, again about 1/9 of that of the St. Lawrence.

The total drainage area of Lake Huron and Michigan including the lake surfaces is found from the aforesaid authority to be 137,807 square miles, and the difference of discharge between the St. Clair River and the St. Mary's Rivers 115,328 cubic feet per second, is equivalent to an average run-off of 0.84 cubic feet per second per square mile for the entire Michigan-Huron drainage, or something over five times as much as that from the drainage area of Lakes Erie and St. Clair.

In order, if possible, to check the probable accuracy of the derived figures of run-off from the several lake basins, an

examination was made of the records of the discharges of rivers as presented in the reports of the United States Geological Survey, of the State Engineer of New York, and of the Report of the Board of Engineers on Deep Waterways, and of unpublished data of the London-Ontario Water Works, and of numerous gagings of rivers in Michigan, mainly from my individual experience, and taking all the information that we were able to find, but probably not all that exists, there was deduced therefrom an average run-off per square mile for each month, and these were combined into an average annual run-off for the drainage area tributary to each lake. For Lake Ontario gagings were found representing 37 per cent. of the drainage area; and the average run-off per square mile of these gagings per year was 1.44 cubic feet per second. For Lakes Erie and St. Clair gagings were found representing 33 per cent. of the drainage areas, and the average run-off from these drainage areas as shown by those gagings was 0.66 cubic feet per second per square mile. For Lakes Huron and Michigan gagings were found covering about 32 per cent. of the drainage areas, and showing an average run-off of 0.85 cubic feet per second per square mile.

Comparing these results with those previously deduced for the average run-off from the entire drainage areas of the lakes taken separately, it is seen that whereas in the first computation, the average run-off of the drainage area of Lake Ontario, including the lake surface as derived from the difference between the Niagara and St. Lawrence discharges, was 1.45 cubic feet per second, the average run-off per square mile as derived from the streams tributary to Lake Ontario was 1.44 cubic feet per second, and, whereas, the average run-off from the land and water surface tributary to the St. Clair River, exclusive of Lake Superior drainage, was 0.84 cubic feet per second, the average run-off indicated by the stream gagings tributary to Lakes Huron and Michigan was 0.85 cubic feet per second, while for Lake Erie from the difference of discharge between the Niagara and St. Clair Rivers, the average run-off from the total drainage tributary to Lakes Erie and St. Clair exclusive of that coming from Lakes Michigan, Huron and Superior, was 0.16 cubic feet per second, the average run-off indicated by the streams gaged tributary to Lakes Erie and St. Clair was 0.66 cubic feet per second, or about four times as much.

The result of this comparison for the drainage area upon Lake Erie being so far out of harmony with the results for

the drainage areas of Ontario and Michigan-Huron led to a further examination to ascertain if it were possible to account for the very remarkable difference which exists between the apparent run-off per square mile from the drainage area of Lake Erie as indicated by the outflow of the Niagara River upon the complainant's figures, and the average run-off from the same drainage area as indicated by the gagings of streams representing about one-third of that drainage area.

Mr. Wilkerson: I move to strike out the answer thus far made and each statement in it on the following grounds: That in each one of the statements of the answer there are assumptions which are wholly unsupported by anything in the record in this case, or in the evidence in the case; as well as references to facts, which nowhere appear from any portion of the record or the evidence in this case.

(In connection with the objection made by the Government's counsel the witness states that he will produce for such examination as may be desired to be made of the same, the different items of facts which he has used as the basis of his computation; and if desired will present the same as an exhibit.)

Recess until 2 o'clock p. m.

After Recess—2 p. m.

GARDNER S. WILLIAMS resumed the stand and testified as follows:

The Witness: My attention having been directed to the apparently abnormally low run-off from the drainage area of Lake Erie and Lake St. Clair, I then proceeded to examine the question in more detail, by reference to the discharges for the period from 1900 to 1904; my reason for selecting this period being that it was the period covered, or most nearly covered, by the drainage measurements which have been presented in this case; and it also avoided the interference with the levels of Lake Ontario due to the construction of the Gut Dam, to which reference has already been made.

The average discharge of the St. Lawrence River by the complainant's equation, as shown on Table XLIII for the period from 1900 to 1904, inclusive, is 240,820 cubic feet per second.

The mean discharge of the Niagara River by the average

of the two equations of the complainant, that at the Bridge Section being 198,068 cubic feet per second, and that at the Open Section 195,390 cubic feet per second, as shown in Tables XI and XII for the period from 1900 to 1904 is 196,739 cubic feet per second.

Complainant's witness Wheeler, file 4 at page 70, being page 166 of the continuously paged record, states the diversion through the Erie Canal to be 1,200 cubic feet per second, and that through the Welland Canal to be 1,100 cubic feet per second, and adding these to the average of the discharges of the Niagara River as just stated, makes a total of 196,739, plus 2,300 equals 199,039 cubic feet per second. Subtracting this discharge from Lake Erie from the discharge from Lake Ontario, we have 240,820 minus 199,039 equals 41,781 cubic feet per second as the quantity contributed from the drainage area of Lake Ontario.

The drainage area of Lake Ontario, exclusive of the lake itself, is, as already stated, 25,737 square miles, and the average run-off per square mile of the streams on which gagings are recorded, which embrace about 37 per cent. of the drainage, and which gagings are of record in the reports of the United States Geological Survey, State Engineer of New York and in some other sources which will be presented for the examination of the complainant, is 1.44 cubic feet per second.

Assuming the 37 per cent. of the area covered by the run-off records to be representative of the whole drainage, the land drainage would contribute to Lake Ontario 37,061 cubic feet per second, being the product of the area, 25,737 square miles by 1.44 cubic feet per second, being the run-off per square mile. Subtracting 37,061 cubic feet per second from the land surface from the run-off from the entire Ontario drainage, as computed above, 41,781 cubic feet per second, leaves to be contributed by rainfall on the lake surface, and subterranean supply, if any, 4,720 cubic feet per second.

The average precipitation at the several United States and Canadian Weather Bureau Stations on the shores of Lake Ontario for the years in question was 35.78 inches. The records of these stations, from which this figure is obtained, will be furnished to the complainant. The area of the surface of Lake Ontario is, as already stated, 7,243 square miles, and the average rainfall when reduced to cubic feet per second, being the product of the 35.78 inches multiplied by 7,243 square miles, and reduced by dividing by the proper factor,

is therefore equivalent to a flow of 19,150 cubic feet per second.

Subtracting from this 19,150 cubic feet per second the excess of the run-off from the Ontario drainage over the run-off from its land surface, as previously computed, which was 4,720 cubic feet per second, leaves 14,430 cubic feet per second more than the run-off of the river accounts for, and this difference, therefore, represents the least amount of evaporation from the surface of Lake Ontario consistent with the premises upon which this discussion is based; which evaporation is equal to 1.99 cubic feet per second per square mile, or to 27.0 inches of rainfall on the lake.

The mean discharge of the Niagara River from 1900 to 1904 has already been stated to be 196,739 cubic feet per second. The Erie and Welland Canals, according to the complainant's witness, added 2,300 cubic feet per second, making the total outflow from Lake Erie 199,039 cubic feet per second for the average of the period from 1900 to 1904 inclusive.

The mean discharge of the St. Clair River, by the complainant's equation for the same period, is 188,787 cubic feet per second, as shown in Table XX. This leaves the amount of water to be contributed to the Niagara River by the Erie and Lake St. Clair drainage as 10,252 cubic feet per second, being the difference between 199,039 cubic feet per second flowing from Lake Erie and 188,787 cubic feet per second flowing into Lake Erie through the St. Clair and Detroit Rivers.

The drainage area of Lake Erie and St. Clair, exclusive of the lakes themselves, is 30,296 square miles, as already stated, and the average run-off per square mile of the streams on which gagings have been examined, which embrace about 33 per cent. of the drainage area, is 0.66 cubic feet per second.

Assuming the run-off as shown from this 33 per cent. of the drainage area to be representative of that from the entire drainage area, the land drainage, therefore, would contribute 30,296 times 0.66 equals 19,995 cubic feet per second, which is more than the remainder of the outflow by the difference between 19,995 cubic feet per second and 10,252 cubic feet per second, or by 9,743 cubic feet per second; and this must then disappear by evaporation from the lake surface, together with rainfall on the lake surface, and the subterranean flow, if any, basing the conclusion upon the premises already stated.

The average precipitation at the several United States and Canadian Weather Bureau Stations on the shores of Lake

Erie for the period in question was 33.77 inches; and the detail of this information will be furnished to the complainant.

The area of the lake surfaces is 10,471 square miles, and multiplying this area by the rainfall and dividing by the proper factor, the average rainfall is therefore equivalent to a flow of 26,050 cubic feet per second. This added to the 9,743 cubic feet per second of excess from the drainage area over the difference between the outflow from Erie and the inflow through the St. Clair River gives a minimum evaporation of 35,793 cubic feet per second, which is equal to 3.42 cubic feet per second per square mile of lake area, or to 46.4 inches of rainfall annually.

Coming to Lakes Michigan-Huron, the mean discharge from the St. Clair River, from the complainant's equation, has already been stated as 188,787 cubic feet per second. The mean discharge of the St. Mary's River as given in the report of the International Waterways Commission on the Regulation of Lake Erie for 1910, from 1900 to 1904, is 76,060 cubic feet per second. Subtracting the latter from the former, we have 188,787 minus 76,060 equals 112,727 cubic feet per second as the amount of water contributed from the Michigan-Huron drainage.

During this period the Chicago Drainage Canal diverted an average of 4,200 cubic feet per second, which makes a total discharge from Lakes Michigan-Huron for this period of 112,727 plus 4,200 equals 116,927 cubic feet per second.

The drainage area of Lakes Michigan-Huron, exclusive of the lakes themselves, is, as already stated, 92,493 square miles. The average run-off per square mile of the streams on which gagings are recorded, which embrace about 32 per cent. of the drainage areas, is 0.85 cubic feet per second. The detail upon which this run-off is based will be furnished for the examination of the complainant.

The land drainage, therefore, contributes 92,493 times 0.85 giving 78,619 cubic feet per second, which leaves to be contributed by the rainfall on the lake surfaces, and subterranean flow, if any, the difference between 116,927 cubic feet per second, the total outflow and 78,619 cubic feet per second, the total inflow from the land drainage, or 38,308 cubic feet per second; the assumption here being, as in the case of the other two lakes, that the run-off from the 32 per cent. of the drainage area is representative of that from the entire drainage.

The average precipitation at the several United States and Canadian Weather Bureau Stations on the shores of Lakes

Michigan-Huron for the period in question was 30.26 inches. The information upon which this is based will be submitted to the complainant. The area of the lake surfaces is 45,314 square miles. Multiplying the average rainfall of 30.26 inches into the area, 45,314 square miles of the lake surfaces and dividing by the proper factor gives an equivalent flow for the rainfall on the lake surfaces of 101,020 cubic feet per second. Subtracting from this the quantity, 38,308 cubic feet per second, which it was necessary to have contributed from the rainfall on the lake surfaces to complete the discharge from the lake, there remains 62,712 cubic feet per second more than the discharge from the lakes account for. And this difference, again, is the minimum evaporation, on the premises on which this investigation is based, which is equal to 1.38 cubic feet per second per square mile, or 18.7 inches.

The foregoing computations have not taken into account the change of stage of the several lakes, during the period considered.

Q. Why is it necessary to take that into consideration?

A. Because if the lakes raised, a certain amount of the water which has been computed as flowing in, was absorbed and stored in the lake; and if the lakes fell, an additional quantity must have flowed out beyond that which came from the land, so that if the lakes raised, then the inflow, or the amount left as evaporation, should be decreased, and if the lakes fell the amount charged to evaporation should be increased.

Between December, 1899, and December, 1904, using the monthly means, Lake Ontario raised 1.45 feet; Lakes Erie and St. Clair raised an average of 0.445 feet; Huron and Michigan raised an average of 0.542 feet; and Superior fell 0.26 feet.

This storage was equivalent to an evaporation from the lake surfaces of the amounts represented in feet when reduced to inches, which is for Ontario 3.48 inches; reducing the evaporation by that amount for Erie and St. Clair 1.07 inches, reducing the evaporation by that amount, and Huron-Michigan 1.29, reducing the evaporation by that amount.

We then have, from the previous computations, an evaporation from Lake Ontario of 27.0 inches which when reduced by 3.48 inches equals 23.52 inches; from Erie and St. Clair, by the previous computation, 46.4 inches, which when reduced by 1.07 becomes 45.33 inches and a computed evaporation from Lakes Michigan-Huron of 18.7 inches which, when reduced by 1.29 becomes an evaporation of 17.41 inches.

The evaporations for Lakes Ontario, 23.52 inches, and Michigan-Huron, 17.41 inches, vary from the mean of the two by less than 15 per cent. as above computed. The total Ontario evaporation is equal to 23.52 divided by 35.78, or 65¾ per cent. of the rainfall on its water surfaces. The total Michigan-Huron evaporation is 17.41 divided by 30.26 or 57½ per cent. of the rainfall on its water surface. Assuming the complainant's testimony and the preceding computations to be correct, the total evaporation from Erie and St. Clair must be as follows——

Q. You mean the testimony which you have referred to?

A. Yes, assuming the complainant's testimony, to which reference has been made in this connection, and the computations and assumptions herein made to be correct, the total evaporation from Erie and St. Clair must be at least 45.33 minus 33.77 divided by 33.77, equals 11.56 divided by 33.77, or about 34.3 per cent. more than the rainfall on its water surface.

The Erie evaporation herein deduced as correct for the storage is nearly 2 1/5 times the mean of that of the other lakes. That the rate of evaporation from Lakes Erie and St. Clair would exceed that from the other lakes has been expected from the shallowness of the water and the effects of winds upon its surface; and by some has been attributed to the direction of its major axis, but so far as the position of its major axis is concerned, Ontario occupies a similar position, and the width of Lake Huron is nearly as great as the length of Lake Erie. Whether or not the shallowness of the water can account for an increase in evaporation of 121 per cent. is to be determined, if at all, by an examination of related data, as there are no direct observations known to me that solve the question.

In 1887 and 1888, there was carried on at the several United States Weather Bureau Stations along the Great Lakes simultaneously for a period of twelve months, with dry and wet bulb thermometers, and the Piche evaporemomeeter, a series of evaporation observations. These observations are published by the United States Weather Bureau in the Monthly Weather Review for September, 1888; and if desired, a transcript of them will be furnished to the complainant.

The evaporation at the Lake Ontario Stations, which were Oswego and Rochester, for the period 1887, 1888, was found to be 30.65 inches, or 60 per cent. more than the rainfall. At Lake Erie Stations it was 35.6 inches, or 20 per cent. more than the rainfall. At the Michigan-Huron Stations it was

29.37 inches, or 7 per cent. less than the rainfall. And at the Lake Superior Stations it was 23.75 inches, or about 22 per cent. less than the rainfall.

On Lake Erie, the evaporation was observed at Buffalo, Erie, Cleveland, Sandusky, Toledo and Detroit. On Lakes Michigan-Huron, evaporation was observed at Port Huron, Alpena, Green Bay, Grand Haven, Milwaukee and Chicago. On Lake Superior, evaporation was observed at Duluth and Marquette.

At the same time, evaporation observations were carried on with similar apparatus by the Weather Bureau at Boston Massachusetts. Rainfalls during this period were for Ontario, 22.49 inches; for Erie, 29.34 inches; for Michigan-Huron, 31.55 inches, and for Superior, 30.39 inches, based upon the observations at the same stations where the evaporation observations were made.

Q. What period do you refer to?

A. 1887-8.

Q. Why is it important to consider the rainfall at that time?

A. Because that has its bearing upon the evaporation. In the case of a large rainfall, it would probably mean that it was distributed over a large number of days, although not necessarily; and while it is raining there can be no evaporation. So that the evaporation would be expected to increase as the rainfall decreased, speaking of evaporation from water surfaces.

This would not hold true upon the land because the land surface would become dry, and there would be no more water to evaporate; so that on land surfaces the evaporation is likely to increase with the rainfall, up to a certain limit at least, but on the water surface, the opposite is generally true.

The evaporations for Ontario and Michigan-Huron is indicated by these observations, varied by about 4 per cent. from the mean, and the Erie evaporation exceeded that of Ontario by about 16 per cent., and that of Michigan-Huron by about 18 per cent.

These observations, while in my opinion they are not to be taken as representative of absolute quantities, I do believe them to represent relative conditions within a reasonable degree of accuracy, and that being the case it does not appear to me that they account for or even suggest the enormous evaporation from Lake Erie which is necessary to account for the discharges derived from the complainant's equations. And it therefore seems evident that there must be some other ele-

ment entering into this question of lake discharge, which has not been considered in the discussion thus far.

In this connection I would refer to the statement, Appendix EEE of the Report of the Chief of Engineers for 1904 at page 4130, paragraph 10, which is as follows:

"The average discharge of the Detroit River for 11 years, 1893 to 1903, is 193,854 cubic feet per second. The average discharge of Niagara River for the same time is 197,328 cubic feet per second. The discharge of Niagara River should be greater than the discharge of Detroit River by the quantity of water coming from the drainage area of Lake Erie. This quantity if taken as a part of the outflow through Niagara River, proportional to the area of the Lake Erie drainage area as compared with the whole drainage of the lakes above Niagara, should be 30,100 cubic feet per second. Either the Detroit River discharge, therefore, is too much, or the Niagara River discharge is too small. If there is no greater difference in the discharges of the Detroit and Niagara Rivers than the observations show, it would indicate an evaporation from the surface of Lake Erie of 81.4 inches for the year, a quantity greater than seems admissible. This assumes a run-off of .6 of the rainfall on the land part of the drainage area of Lake Erie."

This report is signed by Thomas Russell, assistant engineer, addressed to Major W. L. Fiske, Corps of Engineers United States Army.

Q. Where was he located at that time?

A. An assistant engineer in the office of the United States Lake Survey.

Q. At Detroit?

A. At Detroit.

Mr. Wilkerson: Please note the same motion with respect to the remaining portion of this discussion of this subject as was made this morning; and also on the further ground that it appears, from the testimony of the witness, that the data which are assumed as the basis of this conclusion are entirely too indefinite to furnish any foundation for any conclusion such as that which has attempted to be drawn. And I reserve the right to specify further grounds, in support of the motion to strike the discussion of the witness, after the conclusion of the cross-examination, not stopping at this time to cross-examine as to the data upon which the conclusion was based.

Mr. Austrian: You are not objecting at this time on the

ground that you have not been furnished the data that he said he would furnish?

Mr. Wilkerson: Oh, no. I reserve the right to specify further grounds when we have examined the data. But the ground that I last specified here was suggested by the comments made by the witness himself upon the data which he has used as the basis of the conclusion.

Mr. Adcock: Have you made any investigations and conclusions, with reference to the general subject of the changes in lake levels?

A. I have.

Q. Will you state the facts upon which you have made these calculations, the basis of any conclusions which you have drawn, and such conclusions as you may have drawn from such investigations and facts stated?

Mr. Wilkerson: By that you mean he is to tell what changes have taken place in the levels of the respective lakes, and then give us his theory as to why the change has taken place?

Mr. Adcock: With reference to the subject-matter of the investigation, the increment, and so forth; discharge measurements, and the increment derived from the measurements of the different rivers.

A. From Table XIX from Exhibit 34, it appears that the mean elevation of Lakes Huron-Michigan for the 30 years from 1860 to 1889, inclusive, was 581.91, and from 1890 to 1907, inclusive, it was 580.48, or 1.43 foot lower.

Similarly, during the earlier period, Lake Erie was at elevation 572.92, and during the later period at 572.08, or .84 foot lower during the latter period.

Complainant's witness Haskell, file 2, page 46, being page 64 of the continuously paged record, has attempted to explain this lowering on the grounds of deficient precipitation. Table 48 of Exhibit 34 presents the precipitation at typical stations on the various drainages, derived from the records of the United States Weather Bureau, United States Army, Smithsonian Institution, at typical stations on the various drainages. It was necessary to confine the investigation to these typical stations, because they were practically the only ones upon which continuous observations extended back over the period of years in question.

The record for Lake Superior is dependent upon the observation at Marquette; for Lakes Michigan-Huron it is based upon the observations at Milwaukee and Detroit; for Lakes Erie and St. Clair, it is based upon the observations at De-

troit, Cleveland and Buffalo; for Lake Ontario, it is based upon the observations at Buffalo, Oswego, Rochester and Toronto.

As indicated at the foot of the table for a total of six years in the group, the record of Toronto is missing; and during a short period during the three years 1867, 1868 and 1869, the record at Detroit is missing, and is supplied by taking a mean of obseravtions at Lansing and Monroe.

From the data so compiled and presented in Table 48, Exhibit XXXIV, it appears that from 1860 to 1889, as shown in that table, the average annual rainfall on Lakes Michigan-Huron was 32.35 inches; from 1890 to 1907 30.90 inches, giving an excess during the shorter period of 1.45 inches.

On Lake Erie, the average precipitation during the earlier period was 35.77 inches and during the later period 33.71 inches, a difference of 2.06 inches, of excess in the earlier period.

On Ontario, the average precipitation for the earlier period was 35.06 and for the later period 34.13 inches, showing an excess in the former period of 0.93 inches.

As the record of rainfall on Lake Superior is incomplete, in order to eliminate Lake Superior from the computation, I have taken from the report of the International Waterways Commission on the Regulation of Lake Erie for 1910, the average discharge of the St. Mary's River from 1860 to 1889, as 85,300 cubic feet per second, and from 1890 to 1907 as 76,400 cubic feet per second, showing a decrease in the second period of 8,900 cubic feet per second. During 7 of the 18 years of the second period, or 39 per cent., the Chicago Drainage Canal has been diverting an average of about 4,300 cubic feet per second, which would be equivalent to 1,675 cubic feet per second for the whole period.

The total average decrease of outflow due to the above causes, that is, the change of flow of the St. Mary's River, and the Chicago diversion, has been 10,575 cubic feet per second. That is, it is the sum of 8,900 cubic feet, decreased flow of St. Mary's River, and 1,675 cubic feet per second, flow of the Chicago Drainage Canal, which makes 10,575 cubic feet per second. And with an increment in the St. Clair River of 28,872 cubic feet, as derived in Table 33 of Exhibit XXXIV, this would account for a lowering of Lakes Huron and Michigan of 0.366 foot. Of the total lowering of 1.43 foot in Lakes Michigan and Huron, therefore, approximately 0.37 foot seems, by the above analysis, to be accounted for, leaving 1.06 foot of lowering to be charged to deficient precipitation.

Using the same increment as before, this must be due to an abstraction of 1.06 times 28,872, or 30,600 cubic feet per second, which is 30,600 divided by 197,633, or about 15.6 per cent. of the present decreased outflow. The difference of precipitation for Michigan-Huron already cited, is about 4.7 per cent. of the precipitation during the last period, so that if precipitation accounts for this lowering, we find that, reasoning conversely, an increase of precipitation of 4.7 per cent. should increase the outflow of Lakes Michigan-Huron 15.6. The reasonableness of this conclusion may be tested by a comparison with the conditions on Lakes Erie and Ontario.

The discharge of Lake Erie has been increased during the later period by increased diversions through the Erie and Welland Canals, which amount to about 1,000 cubic feet per second, so the total decrease of outflow of the Niagara River, by diversions and decreased flow in St. Mary's River, would be the sum of the decrease of St. Mary's River, 8,900 cubic feet per second, the outflow through the Drainage Canal of 1,675 cubic feet per second, and the increased diversions through the Welland and Erie Canals of 1,000 cubic feet per second, or 11,575 cubic feet per second.

Assuming an increment for the Niagara River of 34,000 cubic feet per second as derived from the comparison between the St. Lawrence and St. Clair Rivers, this would account for a lowering of 11,575 divided by 34,000, or about .34 of a foot, which subtracted from the .84 foot which Lake Erie lowered between the two periods, leaves .5 of a foot to be due to decreased precipitation.

A fall of .5 of a foot represents an abstraction, using the increment of 34,000 cubic feet per second, of 17,000 cubic feet per second. The decreased flow of the St. Clair, previously computed for the same period, was 30,600 cubic feet per second, which is 13,600 cubic feet per second in excess of the abstraction which the fall of Lake Erie accounts for. So that if there had been no change in the rainfall on Lake Erie during the two periods, the lake should be at the least calculation, about 4/10 of a foot lower than it is, were it not for the draft upon storage in Lake Huron-Michigan, which would reduce the lowering about .1 foot; or Lake Erie should be .3 of a foot lower than it was if there had been no change in precipitation.

Now, the precipitation on Lake Erie between the two periods shows that in the former it was 6 per cent. greater than it was in the latter; so that as Lake Erie is too high in the later period, we have the anomaly of a decrease of 6 per cent. in

the rainfall causing a rise in Erie of .3 of a foot, and a decrease of 4½ per cent. on Huron-Michigan, causing a lowering of 1.06 of a foot. So that it does not appear that the two results are consistent, and one or the other or both must be in error.

The level of Lake Ontario by Table 49, Exhibit XXXIV, has fallen from a mean of 246.52 for the period from 1860 to 1889 to a mean of 245.65 for the period commencing 1890 to 1907.

In 1903 there was constructed the so-called Gut Dam across one of the channels of the St. Lawrence, which raised the level of Lake Ontario, according to the complainant's witness Shenehon, file 6, page 43, being page 501 of the continuously paged record, about 5 inches for the period after 1903.

In answer to a question, after the witness had testified that he made certain prophecies based upon computations of the effect of the construction of this dam, the computations being based upon the discharge measurements of the St. Lawrence River, the question is:

"Q. Your computations were borne out, were they, by the actual observations?

A. It came within the limits stated. The actual rise of Lake Ontario, by reason of the Gut Dam, was about 5 inches."

This Gut Dam is indicated on Chart 3 of the St. Lawrence River, being Williams' Exhibit 18, and is shown extending from Galops Island to Adams Island, at the head of the channel marked "The Gut;" and is indicated by the legend "Gut Dam."

The width of the channel cut off is about 450 feet, according to scale on the map. This is located about 6 or 7 miles below Ogdensburg, which makes it about 67 miles below Lake Ontario. Apparently it cut off the flow through that channel entirely.

This dam was constructed by the Canadian Government in American waters, with the consent of the American Government, for the purpose of preventing a bad cross current in the Galops Rapids channel, which was used for navigation by boats going down the river, particularly; and this cross current striking the channel nearly at right angles, was liable to drive boats over against the farther side of the channel. It was constructed, according to the testimony, in 1903. A rise of 5 inches for three years of the 18 in the period, would raise the means 5/6 of an inch.

Q. You are speaking of the rise on account of the—

A. In Lake Ontario on account of the Gut Dam, which cov-

ers three years of this period, and if we distribute that over the whole 18, it becomes 3/18 times 12 times 5, I believe is the way it works out; it comes out about 5/6 of an inch, or .07 of a foot.

Q. The effect of the Gut Dam on the rise of Lake Ontario is still present, is it not?

A. Yes. So that if the Gut Dam had not been constructed, the mean elevation of Ontario during the later period, that is, from 1890 to 1907, would have been 245.65 minus 0.07 equals 245.58, showing a fall between the means of the two periods of 246.52 minus 245.58, or 0.94 feet, or slightly more than Erie. The diversions from Lake Ontario, effective during the later period only, are similar to those from Huron and amount to substantially the same quantity, or about 10,000 cubic feet per second, which, with an increment of 30,322 cubic feet per second, as derived from Table 42 when referred to changes of stage of Lake Ontario, would reduce the level of the lake about 0.33 foot. A further lowering of Lake Ontario of 0.94 minus 0.33 equals 0.61 foot is to be explained. This would represent a decrease of outflow of 0.61 multiplied by 30,322, or about 18,000 cubic feet per second. The decreased outflow of Huron, assuming it to have been due to deficiency of precipitation, as suggested by the complainant, must have been, as before stated, 32,900 cubic feet per second, which is, as in the case of Lake Erie, about 15,000 cubic feet per second more than the fall of Ontario accounts for, assuming no change in rainfall; the difference being 32,900 minus 18,000.

To this a correction should be applied for the contribution from storage on Michigan-Huron of approximately 3,170 cubic feet per second and a similar contribution from Lakes Erie and St. Clair of about 430 cubic feet per second, making a total of about 3,600 cubic feet per second, which would account for about 0.12 foot of this lowering. This reduces the amount unaccounted for to about 11,400 cubic feet per second. But the rainfall on the Ontario drainage appears to have been, from the figures already given, about 2.7 per cent. greater during the earlier period than during the later.

To summarize: on the complainant's theory that a reduction of rainfall accounts for the changes of lake levels—

Mr. Wilkerson: You mean on the statement of one of the complainant's witnesses.

A. Yes. On the statement of the complainant's witness that a reduction of rainfall—

Mr. Adcock: Is that the same witness you referred to—Haskell?

A. I refer to complainant's witness Haskell—that a reduction of rainfall accounts for the changes in position of the lake surfaces, we have a reduction of rainfall on the Michigan-Huron drainage of about 5 per cent., decreasing the discharge of the St. Clair River about 15 per cent., while a decrease of rainfall of about 6 per cent. on the Erie drainage increased the discharge of the Niagara River about 7 per cent.; and a decrease of rainfall of about 2.7 per cent. on the Ontario drainage increased the discharge of the St. Lawrence River about 6 per cent.

It therefore seems impossible, with the information which is available, to derive from the precipitation records satisfactory explanation of the changes in lake levels. And it is my conclusion that a considerable part of these changes is due to causes to be sought elsewhere.

An examination of Table XIX of Exhibit 34 shows that a reduction of the level of Huron-Michigan took place about 1889-90. For the six years preceding, 1884 to 1889, the mean elevation was 582.35; and for the six years following, 1890 to 1895, the mean elevation was 580.53, or 1.82 feet lower.

Lake St. Clair shows a drop at the same time from elevation 576.27 to 575.12, or 1.15 foot; and Lake Erie, a drop from elevation 573.04 to elevation 572.12, or 0.92 foot.

In the report of the Chief of Engineers for 1903, Appendix FFF, pages 2878, 2879, are given tables of precipitation on the several watersheds of the Great Lakes, which were identified by complainant's witness Wheeler.

Q. That was the mean annual precipitation?

A. Gives the monthly also. On the several watersheds of the Great Lakes, such tables being identified and testified to by the complainant's witness Wheeler in file 4, pages 92, 93, being pages 188 and 189 of the continuously paged record.

The mean annual rainfalls as shown in these tables for the periods last under consideration, namely, 1884 to 1889, and 1890 to 1895, were, for Lake Superior in the former period, 26.7 inches, in the latter period 25.60 inches, a decrease of 0.47 inches, or 1.8 per cent. On Michigan-Huron, for the former period an average precipitation of 32.07 inches, for the later period 31.91 inches, showing a difference of 0.16 inches, or 5/10 of 1 per cent. On St. Clair-Erie, for the former period, an average precipitation of 32.39 inches, for the latter period 34.94 inches, showing an increase of 2.55 inches, or 7.3 per cent. On Ontario, during the former period, an average pre-

cipitation of 34.83 inches, during the latter period 38.97 inches, showing an increase of the latter over the former of 4.14 inches, or 10.6 per cent.

From the Report of the International Waterways Commission, page 101, being the Report upon the Regulation of Lake Erie for 1910, to which reference has already been made, the flow of the St. Mary's River during the period from 1884 to 1889 is shown to have been at the rate of 78,616 cubic feet per second, and during the later period at the rate of 71,600 cubic feet per second, showing a decrease of 7,016 cubic feet per second between the two periods. And the surface of the lake, by Tables L of Exhibit 4 was at the same mean elevation for both periods.

The discharge, therefore, appears to have been reduced 9 per cent. by a decrease of rainfall of less than 2 per cent.

Complainant's witness Wheeler, in the report above, makes these discharges for the St. Mary's River, 70,388 cubic feet per second for the former period and 65,789 cubic feet per second for the later period, giving a difference of 4,590 cubic feet per second, discharge of the St. Mary's River, as computed by Mr. Wheeler and identified by him, as shown upon page 2,873 of Appendix FFF to the Report of the Chief Engineers for the year 1903.

The holding back of 7,016 cubic feet per second in Lake Superior would lower Lakes Michigan-Huron 7,016 divided by 28,872, equals 0.24 foot. So that on the theory of the complainant's witness Haskell, a reduction of 5/10 of 1 per cent. of the rainfall lowered these lakes 1.82 minus 0.24, equals 1.58 foot, equivalent to reducing the discharge 1.58 times 28,872, equals 45,600 cubic feet per second; and a rainfall of 0.16, which is the difference between the rainfall of the earlier and later period on Michigan-Huron, on the area of the land and water drainage of Michigan-Huron, would only amount to 1,624 cubic feet per second on a lowering of 0.056 of a foot, if we assume that all of this decreased rainfall would have reached the lake if it had not decreased, thus leaving 1.52 of a foot lowering, or a discharge of 44,000 cubic feet per second to be accounted for.

The rainfall of St. Clair and Erie shows an increase in the second period over the first, as does also that of Ontario; the former of 2.55 per cent., and the latter of 4.14 per cent.; yet Lake Erie lowered 0.92 of a foot between the two periods, and Lake Ontario lowered 0.53 of a foot.

From the foregoing it seems clear that some other cause

than reduced rainfall must be found to account for the changes of lake levels about 1889.

Mr. Wilkerson: I make the same motion with respect to this discussion on precipitation; with the same statement as to the furnishing of data, and as to the opportunity for cross-examination. And if I may be permitted, I would like to have this understanding, not only with reference to the testimony of this witness, but with reference to the witnesses who are to be examined in the future. It is obvious that the competency of a great deal of this hypothetical testimony, which is based upon assumptions of fact made by the witness, cannot be determined until the data from which the conclusions are drawn have been subjected to the test of the cross-examination of counsel; and I will reserve making any such motions at the time the evidence goes into the record, with the understanding that upon the conclusion of the Government's cross-examination of the witness, I will reduce these motions to strike the evidence, and such objections as go to the competency, materiality or relevancy of the evidence, to writing, and submit them to the counsel on the other side, and hand them to the Commissioner.

Mr. Austrian: And we will have an opportunity then, to supply and correct so far as we can, any testimony, to which the objection goes.

Mr. Wilkerson: Of course, you would have an opportunity for further examination of the witness after the objection is made.

Adjourned to Tuesday, March 25, 1913, 10 o'clock a. m.

March 25, 1913, 10 o'clock a. m.

Parties met pursuant to adjournment.

Present same as before.

GARDNER S. WILLIAMS resumed the stand and testified further as follows:

Mr. Adcock: Referring to Table LIII, Mr. Williams, will you state how you have compiled that table and what it refers to?

A. Table LIII presents the cubic yards of material reported as removed from the channels of the St. Clair River, Lake St. Clair and the Detroit River from 1870 to 1910, the table being based upon the reports in the annual reports of

the Chief of Engineers covering the several localities that are indicated at the top of the table.

The first column gives the year in question; the second column covers the region at the lower end of Lake Huron, being the head of the St. Clair River, at which in the early days there was a bar upon which the depth of water appears to have averaged about 12 or 13 feet. The second column is headed "Mouth of Black River," and refers to the shoal which has been repeatedly dredged in front of the City of Port Huron; this shoal apparently reforming to a considerable extent after having been removed on altogether five different occasions.

Mr. Austrian: Are you referring to sheet 1?

A. I am referring to sheet 1 and sheet 2.

Q. Taken in connection with each other?

A. Taken in connection with each other.

Mr. Adcock: They are all a part of the same table?

A. All a part of the same table.

Mr. Austrian: What do the figures indicate?

A. The figures indicate the number of cubic yards of dredging reported as being done in these localities in the reports of the United States Engineer in charge of the work in the district, as published in the reports of the Chief of Engineers.

Mr. Adcock: And you refer to the specific portions of the reports, or any particular reports which make this up, if there is any dispute about it.

Mr. Wilkerson: This I understand is a compilation made from the Government's reports?

A. This is a compilation made from the Government reports.

Q. And you have a memorandum indicating what—

A. It indicates the year. I have the memoranda giving the information in detail. It is all compiled from the report of the engineer in charge of the Detroit office; begins with the reports, I believe, of General Poe. It is the report of the Detroit office, all the time.

Q. This, I understand you to say, shows the total quantity moved, without showing the disposition?

A. This shows the total quantity moved or reported moved from the channel.

Mr. Adcock: At the particular points indicated?

A. At the particular points indicated, or in the particular localities indicated.

The third column, which is headed "St. Clair River," cov-

ers those portions of the St. Clair River below the Black River shoal and above the St. Clair Flats Canal.

The fifth column headed "St. Clair Flats Canal," covers the excavation in connection with the improvement of the St. Clair Flats Canal; that is, at the foot of the St. Clair River.

The sixth column headed "Grosse Point Cut," refers to that channel which was dredged in the nineties across the lower end of Lake St. Clair, cutting away the bar at the head of the Detroit River, which prior to that time had restricted navigation—or given a restricted depth of about 16 feet at low water.

The next column, that is, the seventh, gives the total amount of material removed from the St. Clair River and Lake St. Clair.

The eighth column gives the amount of material removed from Ballard's Reef, so-called, which is the upper obstruction in the Detroit River, and is situated a short distance above Amherstburg, on the Canadian shore.

The ninth column gives the excavation reported for the Lime Kiln Crossing, which is a short distance below Ballard's Reef; and from the reports, it is evident that at times the work on the Lime Kiln Crossing included work on Ballard's Reef, and *vice versa,* so that these two improvements are to be considered as practically one and the same thing, except that there is not a duplication in the figures.

The tenth column, which is marked "Outlet," indicates the material removed from the Detroit River below the Lime Kiln Crossing in the shoals, mainly of earthy material, which existed at the mouth of the Detroit River, or at the head of Lake Erie. The excavations at Lime Kiln and Ballard's Reef were to a considerable extent in rock.

The eleventh column is headed "Livingstone Channel," and gives the excavations as reported from the Livingstone Channel for the years 1908, 1909 and 1910. This channel was completed in 1912, but the figures have not been extended to cover that date, as they were not accessible to us at the time this table was prepared.

The next to the last column gives the total excavation in the Detroit River from Ballard's Reef to the outlet inclusive, and the last column of the table gives the grand total of all excavations reported for the St. Clair and Detroit Rivers in the years in question. At the bottom of the table—

Q. When you say, "St. Clair and Detroit," that includes Lake St. Clair, doesn't it?

A. And Lake St. Clair, yes. At the bottom of the table,

the first page, are given the totals of each column for the periods from 1870 to 1892, inclusive; and at the bottom of the second sheet are given the totals for the periods from 1893 to 1910, from 1870 to 1892 and for the entire table from 1870 to 1910 inclusive.

There is also at the lower right-hand corner of the table a statement of the total amount of material removed from the channels from 1903 to 1910, which is 14,975,331 cubic yards, out of a total for the entire period of 25,290,830 cubic yards.

Q. What other investigations have you made with reference to channel improvements of the St. Clair and Detroit Rivers and Lake St. Clair?

A. I made, in the late nineties, an examination of the effects of the channel improvements in the St. Clair River upon the water supply of Detroit, and had occasion at that time to examine very carefully the original records of the dredging inspectors in the United States Engineer's office at Detroit, through the courtesy of the chief officer in charge; and also to refresh my personal recollections of a considerable portion of this work which was carried on under my observations, to the extent that I could see it going on during my connection with the Detroit Water Works. And it was my recollection of the large amount of work that was done at this time that first directed my attention to that as a possible explanation of the change in lake levels which occurred about 1889 and 1890, as shown by the tables which have been put in evidence heretofore.

This led to a more careful investigation of the relations between the excavations in the channel—I will say of the apparent relations between the excavations in the channels and the changes in lake levels, which has been made by a study of the reports of the Chief of Engineers upon the subject, by conversations with engineers and others who were associated with the work, and by reference to personal memoranda which had been taken from time to time, bearing upon the subject, in the course of my professional work independent of this case.

Mr. Wilkerson: All the work in these channels, about which you are speaking now, was work done by the Government under the authority of the War Department?

A. Yes, sir. There is nothing included in LIII which has not been done by the authority of the War Department under the direction of the engineer officer in charge of the district.

There has been in certain localities considerable further excavation for commercial purposes, particularly recently in

the vicinity of Port Huron, at the head of the St. Clair River, where, within a few years, the removal of material for building purposes (that is, for the sand and for the gravel) was stopped, as a result of the influence brought to bear by the United States Engineer Office upon the Canadian authorities, as I am informed.

Mr. Wilkerson: That is, it was work that was being done by Canadians?

A. It was work being done by Canadians, which it was conceived would interfere with—possibly increasing the outlet of Lake Huron, and interfering to that extent with navigation.

Q. The War Department protested, with the result that the work was stopped?

A. The protest was lodged, and as a result the work was stopped. I do not know whether it went clear through the official channels, or was arranged locally. It is all a matter of record; it could be looked up.

Mr. Adcock: Will you state what conclusions you have reached, and the basis of such conclusions, giving the facts which you have considered in connection with such channel improvements, as to their effect upon the lake levels?

A. The first important work done towards improving navigation in the waters connecting Lakes Huron and Erie was the creation of a 12-foot channel through the St. Clair River, which was completed about 1858, by the construction of the St. Clair Flats Canal. Prior to this, the limiting depths in the latter river, which was at the Flats, was about 9 feet. My impression is that was the mean.

Q. That is prior to what time?

A. Prior to 1858. It is difficult to discover any effect of this improvement upon the level of Lake Huron, for the reason that there are on record no accurate or reliable elevations of the lake for this period, by which it can be compared with the elevations of other lakes for the period prior to this improvement. There are some elevations about this time, but they do not extend back far enough to give a sufficient average to warrant a statement as to the actual effect of these improvements.

The St. Clair Flats Canal, at which these improvements were made, is shown on Williams' Exhibit 7 entitled "Chart of the St. Clair River, including foot of Lake Huron and St. Clair Flats Canal," in the lower left-hand corner of the chart; and the original channel, which was improved in 1858, is represented by the legend, "St. Clair Flats Canal," and extends

between the two upper lighthouses indicated as "St. Clair Flats Canal, Upper Light," and "St. Clair Flats, Lower Light;" the lighthouses being indicated by red dots in a yellow field.

It will be noted that beyond the portion of the channel which is marked "St. Clair Flats Canal," there is an extended dredged area reaching out into Lake St. Clair, indicated by the white through the blue, and the excavations from this channel have been included in the column marked "St. Clair Flats Canal," in Table LIII just described.

Between 1867 and 1871, the St. Clair Flats Canal was deepened to 13 feet, and progressively until 1874, to 16 feet. At the same time, the Lime Kiln, at the mouth of the Detroit River, was similarly deepened. The location of the Lime Kiln is shown upon Williams' Exhibit 9, being a chart of the Detroit River; being located approximately opposite and just above Ft. Malden, which is about a mile above the town of Amherstburg; and is substantially opposite the coffer dam represented attached to Stony Island in the lower half, or lower quarter of the chart.

This early improvement of the Lime Kiln consisted largely in the removal of loose boulders, and did not involve the removal of any large quantity of material. These improvements were followed, in 1874 to 1879, by the removal of the bar at the mouth of Black River at Port Huron, which is shown on Williams' Exhibit 7, "Chart of the St. Clair River, etc.," the bar being indicated by the blue coloring opposite the lower end of the City of Port Huron, at the upper end of the St. Clair River and near the top of the chart. The Black River is seen emptying into the St. Clair, cutting the City of Port Huron into two parts. The purpose of this improvement was to produce a navigable depth along the city frontage of 15 feet.

After the completion of this work, the famous Lime Kiln Channel enlargement was begun, in 1876, and continued until its final completion in 1891. This enlargement was in the locality indicated previously on the chart of the Detroit River, and contemplated a depth of water of 20 feet at the average stage.

In 1888 the Lime Kiln Channel had been completed to a width of 300 feet throughout its length, giving a depth of about 20 feet of water; and in 1889 a width of 350 feet could be depended upon.

Mr. Austrian: You say "throughout its length;" have you given its length?

A. I have not. The improvement covers about, altogether, that improvement which extended not only through the Lime Kiln, but up through Ballard's Reef, covers about four miles of river, the aim being to dig out the shallow spots. There were deep spots in that length, where no improvement was necessary.

During the same year, and the year following, 1889 and 1890, a large amount of material was again removed from the bar at the mouth of Black River; a depth of over 16 feet being secured, and a consequent enlargement of the carrying capacity of that portion of the St. Clair River being produced.

The effect of the improvements between 1876 and 1891 does not appear in its completeness until about 1890, although the changes in lake levels coincident with it are indicated, as shown in Table XIX by the decrease in fall between Lake Huron and Lake Erie, as far back as 1887.

In 1893, four, five and six, very extensive channel improvements were made at the foot of the St. Clair River, and through Lake St. Clair, by the dredging of a 20-foot channel through the bar at the foot of Lake Huron. The location of this dredging is shown on Exhibit 7, "Chart of the St. Clair River" at the top of the chart; the dredging taking place right at the head of the St. Clair River, and extending up some three or four miles into the lake. That channel, if my memory serves me correctly, was 2,500 feet wide, and the bottom was cleaned off to a depth of 20 feet.

The amount of material excavated at this point, as shown in Table LIII during the years 1893 to 1897, was nearly one million cubic yards.

In 1893, work on the Grosse Point Channel was commenced, and extended to the end of May, 1897. Grosse Point Channel is located at the head of Detroit River, at the foot of Lake St. Clair; and is shown on Williams' Exhibit 8, "Chart of Lake St. Clair," the lower left-hand corner of the chart. It extends from the deep, or white water indicated in Lake St. Clair, to the head of the Detroit River, a distance of between two and three miles. From this locality, over five and a half million cubic yards of material was reported to have been handled during the period of this improvement, giving a 20-foot depth entirely across Lake St. Clair.

Mr. Austrian: When you say "reported," you mean what?

A. Reported in the reports by the Engineer Officers, or reported by the Engineer Officer, to have been removed. In 1908, work began on the Livingstone Channel, through the

Lime Kiln, and in 1908, 1909 and 1910 nearly 9,000,000 cubic yards of material are reported by the Engineer Officer to have been removed; and about 400,000 cubic yards more were removed along the old channel, in this vicinity.

The Livingstone Channel is shown upon Williams' Exhibit 9, "Chart of the Detroit River," the upper end of it being enclosed in the coffer dam attached to Stony Island just above the town of Amhertsburg on the Canadian shore, all of which is in the lower left-hand quarter of the sheet.

During the construction of the Livingstone Channel, the upper end of it was enclosed in a coffer dam, that the excavation through the rock might be made in the dry. And the first effect of this improvement was to reduce the discharging section of the Detroit River, raising the water above the coffer dam, and ultimately in Lake St. Clair to a small extent. This channel was completed in 1912 and the coffer dam removed, so that water was free to flow through the excavation in the rock underneath the coffer dam as made in August, 1912, since which time it has added to the discharging capacity of the river as it existed prior to the opening of the coffer dam.

The change in conditions at the head of the St. Clair River is shown by a comparison of plates 7 and 8 of Exhibit 34, of which plate 7 is a photograph of a portion of the chart of the St. Clair River, secured from the United States Lake Survey Office in 1897, by me, which is stamped with the legend, "Aids to Navigation corrected from information received to April 20, 1892." To this photograph have been added in ink two parallel lines enclosing the bar opposite Fort Gratiot; and there has been added in ink "Datum 582.489," being the elevation to which the soundings are referred, when corrected for the revised levels of 1903. The soundings on this chart—

Mr. Adcock: What do you mean by "Revised levels of 1903?"

A. The revised levels of 1903 is a term used to designate the correct elevations of bench marks along the lakes, as a result of precise level determinations, which were made between 1900 and 1903, connecting the benches in this section of the Great Lakes with the benches which had been previously connected to tidewater. It was found as a result of these levels, which were very carefully run, that there were small errors in the old elevations of the benches, in some of them the errors being greater and some less. And in the report of the Chief of Engineers for 1904, Appendix EEE, page 4070, are given the elevations in Table I of bench marks by

what is designated as the old and new levels. The old levels are now referred to ordinarily as 1877 levels, being based upon the determiantions made by the Lake Survey in 1877; and the new levels are referred to as the 1903 levels, being based upon the determinations made by the Lake Survey in 1903.

It will be noticed that the changes which are shown in the third column of the table are comparatively small. The largest change in this table appears at the U. S. bench mark E at Harbor Beach, which, according to the new levels, is 0.507 feet higher than it was according to the old levels.

I would say that all the elevations of lakes given in the exhibits so far introduced have been those referred to the 1903 levels, but it is necessary to keep that fact in mind, because in connection with some of the records, or in connection with all of the records published prior to 1903, the reference is to the 1877 levels, and the elevations would be in error by the amount of the correction which is indicated in this table, for the particular locality.

Since 1903 there has been an additional correction of 6/100 of a foot, or .06, affecting the levels of Lake St. Clair; and this correction has been taken into account in the elevations presented in the exhibits so far in this case. That will be detected by a difference in the elevations of Lake St. Clair, as presented in the report of the International Waterways Commission on the Regulation of Lake Erie for 1910, and the elevations for Lake St. Clair as presented in the blue print exhibits in this case, so that by the levels of 1903, as readjusted, I think in 1910, the level of Lake St. Clair has been found to be .06 higher than was indicated prior to that time, and as shown in the reports of the International Waterways Commission.

Plate 8 is a photograph of a portion of the chart of the same river, being Williams' Exhibit 7, "Chart of the St. Clair River," upon which two parallel ink lines have been drawn, as near as I was able to draw them in the same position as those on plate 7, and the datum elevation has been entered in ink as 578.50, which is taken from the legend on Exhibit 7.

On Plate 7 the soundings marked in the area between the two ink lines enclosing Fort Gratiot Light, omitting only the eight fathoms which is just above the bar on the left-hand side, and which by comparison with the latter chart appears to be an error, as it is hard to conceive how there could have been eight fathoms of water there in 1877, and only 24 feet

plus the change of datum in 1910, for that reason I have omitted that eight fathoms from the computation. Taking the average depth of the other soundings indicated between those two lines on the chart, based on the surveys of 1877 and purporting to be corrected to 1892, the average depth through this area is 22.1 feet below the datum of 582.49, or an average bottom elevation of 560.4 feet above sea level.

Plate 8 is from a chart of the same river, stamped: "Issued May 10, 1911," and at the bottom in the center bears the legend, "Aids to Navigation, corrected from information received to May 10, 1911, March 23rd, 1912, August 24, 1912."

On this latter plate, photographed from the chart purporting to represent the conditions of the channel at the head of the St. Clair River, the soundings in the area enclosed between the similar parallel lines show an average depth of 28.4 feet below the datum elevation of 578.50, or the average bottom elevation of 550.1 feet. Comparing this with the average bottom elevation shown on the photograph of the former chart, Plate 7, it indicates a difference of average bottom elevation through this section of 560.4 minus 550.1, or 10.3 feet. In other words, it is apparent by the comparison of these charts, that the channel through the bar at the foot of Lake Huron, which must have been to a very large extent the controlling factor in the outflow of Lake Huron, has been deepened 10 feet for its average width from shore to shore, between the times covered by the information contained in these two charts.

Since the conclusion of the discharge measurements of 1902, there has been removed from the waters connecting Lakes Huron and Erie, about 15,000,000 cubic yards of material. If this excavation were concentrated in a continuous stretch of 20 miles, 20 miles covering the entire distance over which such improvements have been made, it would make a channel 600 feet wide and 6¼ feet deep.

The effect of this work has been, according to the report of the Chief of Engineers for 1911, page 3013, to increase the discharge of the St. Clair River for the same stage by about 3 per cent. And 3 per cent. of the discharge of the St. Clair River, as indicated by the measurements from 1889 to 1902 would be about 5,700 cubic feet per second.

Mr. Wilkerson: You spoke of averaging these figures on Plates 7 and 8?

A. Yes.

Q. You mean to say that you averaged the figures just as they appeared on those plates?

A. Just as they appeared.
Q. As they are photographed here?
A. Yes.
Q. And giving equal weight to each figure?
A. Equal weight to each figure. There was no attempt to reduce at all.
Q. And you took the figures as they appeared on Plate 7, and the figures as they appeared on Plate 8?
A. Yes. Now, comparing the information on Table LIII with Table XIX of Exhibit 34, which shows the mean annual elevations of the Great Lakes, and the difference in elevations, it is noticed at once that the very marked fall which occurred in Lake Huron with reference to Lake Erie, about 1889, was coincident with the completion of the Lime Kiln Channel at the foot of the Detroit River, which removed what had been, up to that time, an effective weir, controlling to a very large extent the discharge of the Detroit River. This bar was cut through during the previous years, the channel being gradually widened until, as stated, in 1888 it was 300 feet wide. By that time, the increased discharge of the Detroit River had lowered Lake St. Clair and produced an increased flow through the St. Clair River, which in turn lowered Lake Huron, and the effect upon Lake Huran became apparent suddenly about 1889 or 1890. The lowering of Lake Huron is seen, by Table XIX, to continue through the following ten years, being coincident with the large excavations across Lake St. Clair, at the head of the St. Clair River, and further excavations in the Detroit River. The comparisons of these two tables offers to my mind a clear explanation, and a sufficiently complete one, of the changes in the lake levels which occurred about 1889, and which has been heretofore attributed to changes in precipitation and evaporation.

The mean elevation of Lake Huron from 1860 to 1889 was 581.91; the mean elevation from 1890 to 1912 has been 580.43, or 1.48 feet lower.

The mean elevation of Lake Huron from 1884 to 1889 inclusive, was 582.35; and the mean elevation from 1890 to 1895, inclusive, was 580.53, or 1.82 feet lower. In other words, between those two six-year periods—and I take six years in order that I may eliminate any influence of deficient precipitation in a single year; ice, or anything that might make the reference to a single year misleading—the difference of elevation between these two six-year periods has been 1.82 feet. No such sudden drop in the level of Lake Huron is observable anywhere else in its history, so far as our data of elevations

go, and it must have been caused by some particular and special cause, some unnatural cause, as no natural cause can be conceived, which would produce such a remarkable change as this one. That unnatural cause is found in the evidence of Table LIII, in the excavation of material from the Lime Kiln Crossing at the foot of Detroit River, which, prior to its excavation, had controlled the discharge of the river. When this channel was cut through, it enabled the water to flow away more freely, the discharge of the River was increased; the result was a lowering of Lake St. Clair, which increased the fall from Huron to St. Clair, thereby increasing the flow of the St. Clair River and decreasing the level of Lake Huron, as indicated in the actual observations of elevations.

It is possible to determine approximately the amount by which the discharge of the St. Clair River has been increased between its mean discharging capacity for the period from 1860 to 1889, and the period from 1890 to the present time. This may be determined by reference to Table XXI of Exhibit 34, which shows that the fluctuations of Erie, with reference to Huron, during the period from 1860 to 1889 were 75.3 per cent.; and during the period from 1891 to 1910 85.5 per cent., during the latter period. As there has been no marked change, so far as we know, in the discharging capacity of the outlet of Lake Erie during this period, it follows—

Mr. Adcock: During which period?

A. During any of the period from 1860 to 1910. It follows that the conditions of fluctuation, as related to increment, must have been practically constant for Lake Erie during this time; and therefore, it affords a saisfactory standard of comparison for the fluctuation of Huron during the two periods. This fluctuation, as presented in Table XXI, is based upon the mean annual change of elevation of the two lakes.

Then the fluctuations of Huron in the later period as compared to those in the earlier period will be as 75.3 divided by 85.5, or as 0.88; or the fluctuation in the later period will be 0.88 of the fluctuation in the earlier period.

Q. That is the fluctuation in Huron?

A. Of Huron,

Q. That is, the two periods being from—

A. The two periods being, the first from 1860 to 1889, and the second from 1891 to 1910.

This being the same reservoir involved, there are no modifying influences to affect the general rule that the fluctuation is inversely as the increment, and therefore the increment

of the St. Clair River during the earlier period must have been about seven-eighths per cent. of the increment during the later period.

Q. That is, the smaller the increment, the greater the fluctuation?

A. The greater the fluctuation.

Q. The greater the increment, the smaller would be the fluctuation?

A. The smaller will be the fluctuation, because in order to discharge a given quantity of water with a small increment, the lake must rise higher in order to get that water out; and conversely to discharge a given quantity of water with a large increment, it is not necessary for the lake surface to rise so high.

Now, by the principle already enunciated, that when a change is made in an open channel, which increases the increment, the discharge will be changed in a greater proportion than the increment is changed, it follows that the discharging capacity during the period from 1860 to 1889 must have been at the greatest not to exceed 87½ per cent. of that for the period from 1891 to 1910.

Q. You mean the discharge or the discharging capacity of the channel?

A. The discharging capacity. The average discharge of the St. Clair River, from 1900 to 1907, has been computed by the defendant's equation, as shown on Table XL, to be 197,633 cubic feet per second, and it therefore follows that for the same stages as existed between 1900 and 1907, under the conditions of channel existing from 1860 to 1889, the discharge of the river must have been less than 87½ per cent. of 197,633, or less than 172,500 cubic feet per second.

It therefore follows that the changes which have been made in the channels of the St. Clair and Detroit Rivers, beginning with the work upon the Lime Kiln Channel, which was completed in 1891, have had the effect of increasing the discharging capacity of the St. Clair and Detroit Rivers for an average stage, as represented by that existing from 1900 to 1907, by not less than 25,000 cubic feet per second, which is equivalent to an ultimate lowering of these lakes, of not less than 10.4 inches, using the increment derived by the defendant for the conditions of the later period as shown in Table XXXIII.

Q. Have you computed the increment for the previous period?

A. The increment for the previous period would be 87½

per cent. of that for the later period, or about 25,300 cubic feet per second.

Q. What would have been the lowering by this increased discharge, according to the increment deduced for the earlier period?

A. Approximately one foot. It has already been pointed out in my testimony that the effect of the storage in Lake Superior and the diversion through the Chicago Drainage Canal would account for a lowering of Lake Michigan-Huron of about .37 of a foot, and by the changes in the channel, we have accounted for a lowering of nearly 9/10 of a foot, which leaves about 3/10 of a foot to be explained by conditions not definitely determinable, as rainfall and evaporation effects, and other climatological influences.

Direct examination of witness adjourned.

Recess until 2 o'clock p. m.

Depositions in the above entitled cause, taken pursuant to stipulation of counsel for the respective parties, before the Commissioner, statutory notice being duly waived, at the Plaza, New York City, commencing July 17, 1913.

Appearances: Mr. James H. Wilkerson, representing the Government. Mr. Edmund D. Adcock and Mr. Alfred S. Austrian, representing the Sanitary District.

All objections to questions, answers and exhibits shall be considered as having been made, except as to questions involving form and secondary evidence.

GARDNER S. WILLIAMS resumed the stand for further direct examination by Mr. Adcock, and testified as follows:

Q. I think in your previous examination, you stated that the discharge of the Detroit River was measured in the year 1901. Have you made any examination of the discharge measurements of that river, as shown by the records in the Lake Survey office?

A. I have made an examination of the published reports of the discharge measurements of the Detroit River, as they are presented in the Report of the Chief of Engineers for 1903, Appendix FFF, pages 2816-17.

There is also some further information in regard to these

measurements in the report for the year 1902, page 2867; but the 1903 report is the summarization of all the work.

Q. Will you state what investigations and examinations you made, and the conclusions that you have reached?

A. These discharges were examined with a view to ascertaining whether they would support the conclusions drawn from the other observations, whether by any chance they might corroborate the Niagara discharges, or whether they would corroborate the St. Clair and St. Lawrence discharges, or whether they might be inconsistent with all of them.

As previously stated, the discharge of the Detroit River was measured at Ft. Wayne, just below the City of Detroit, by Mr. Murray Blanchard, under the direction of Professor E. E. Haskell, a witness for the complainant in this case, between June and December, 1901, and between June and November, 1902, all inclusive. The results are published, as previously stated, and the discharges are there referred to gauge readings at Windmill Point, on Lake St. Clair, which is a short distance above the head of the Detroit River, and at Ft. Wayne, the gauging section, and at Amherstburg, at the foot of the Detroit River which is really a short distance upstream from the mouth. As published, the gage heights are in terms of the so-called "1877 levels" and when transferred to the "1903 levels," the mean results are:

	Windmill Pt.	Ft. Wayne	Amherstburg	Discharge
1901	574.84	573.99	571.55	201,237 cfs
1902	575.12	574.39	572.71	196,871 cfs
1901–2	574.99	574.20	572.34	198,960 cfs

In explanation I might say that the results for 1901-2 are not the averages of the figures given above, but are the means of all the observations during the entire period; the number of observations being different in the two years. The discharge of the Detroit River is influenced, not only by the elevation of Lake St. Clair, but also by that of Lake Erie, so that an increment cannot be derived by the simple processes used for the Niagara and St. Lawrence Rivers, but must involve a procedure similar to that adopted for the St. Clair.

The number of observations involved on the Detroit does not permit so thorough an investigation as that made on the St. Clair, but by grouping the observations with first one lake constant and then the other, the increment due to Lake St. Clair alone appears to be 45,380 cubic feet per second; and that due to Erie alone, 17,290 cubic feet per second.

From Table XXI of Exhibit 34, it has been shown that Lake Erie's annual fluctuations are 0.855 of those of Huron,

while those of Lake St. Clair are 0.894 of Huron, whence the fluctuations of Erie are the ratio of these two, or 0.956 of those of Lake St. Clair.

The average net increment of the Detroit River from 1890 to 1910 would therefore be 45,380 minus .956 times 17,290, which equals 28,850 cubic feet per second, or substantially the value previously determined for the St. Clair.

The reason for saying that this covers the period from 1890 to 1910 is that we accept these observations made in 1901 and 1902 as representing an average of the conditions of the Detroit River from 1890 to 1910 except as the lake was affected by the work at the Livingstone Channel.

It is to be recalled that the similar process of computing an increment, when applied to the St. Clair gave a value about nine per cent. less than that finally obtained by a more precise determination, and a similar discrepancy may be expected in the case of the Detroit, so that an increment for the latter of about 32,000 cubic feet per second is to be predicted from the preceding result.

The number and range of the Detroit observations are not sufficient to permit of such a treatment as that finally adopted in the case of the St. Clair, but the observations on the Detroit River may be divided into five groups, including altogether 93 out of a total of 117 observations.

Q. What is the treatment you refer to there, with reference to the St. Clair?

A. The treatment of grouping is at times when the stage of the lakes were uniform, or that is, were reasonably constant. There are not enough points to be derived to get a satisfactory equation.

Q. Do you remember what tables those were referred to?

A. Yes. As set forth in Tables XXVIII and XXXIV.

Q. Of Exhibit 34?

A. Of Exhibit 34. I was able to get 93 out of 117 and thereby form five groups, which covered periods as follows:

July 19 to August 3, inclusive, 1901, 11 observations.

August 15 to September 7, inclusive, 1901, 25 observations.

October 7 to October 21, inclusive, 1901, 11 observations.

July 1 to August 2, inclusive, 1902, 26 observations.

October 14 to November 4, inclusive, 1902, 20 observations.

Mr. Wilkerson: Have you a statement there of the ones which you did not consider?

A. No; they can be identified in the table. The reason for leaving out any was, there was either a break in the time of observation, so that they were isolated observations, or

there was a marked change in the conditions as indicated by the change in discharge, so that what I was endeavoring to get here was a group of observations that represented reasonably constant conditions on the two lakes.

Q. I was just inquiring as a matter of convenience so that we would know if you have any tabulation formed of the ones not considered.

A. No, I have not. They are in the report, and you can refer to them.

Having the gage elevations at Windmill Point and Amherstburg, and the discharge for those five groups, it seemed that it should be possible to derive an increment for the Detroit River from these five equations. The method of least squares was applied, and most absurd results were obtained, or absurd results were obtained; the net increment being about 16,000 cubic feet per second, which is on the face of it impossible, since the Detroit increment must be greater than that of the St. Clair, and nobody as yet has conceived a method to bring the increment of the latter to a value less than 16,000. This indicates that the relations between the variables in the equations are not sufficiently established to permit the derivation of an increment from them, although the discharges may be measured with a reasonable degree of precision. The average of the discharges measured for the five periods is 200,880 cubic feet per second. The average discharge of the St. Clair River for the same periods determined by taking the average lake elevations at Harbor Beach and St. Clair Flats for the entire time covered by the five observation periods, and applying the defendant's equation is 201,500 cubic feet per second, or within 620 cubic feet per second of the average of the Detroit measurements.

During the time included in the selected periods, Lake St. Clair as shown by the gage at Windwill Point, comparing its elevation on the first and last days of each group rose .39 of a foot. Since Lake St. Clair has an area of 503 square miles, a rise of one foot in one day would be equivalent to a storage of 162,300 cubic feet per second, and a rise of .39 in the 140 days covered by the selected periods would, therefore, represent a storage of 450 cubic feet per second, so that in the preceding comparison the computed discharge of the St. Clair River for the entire length of the five periods exceeds the average of the observed discharges of the Detroit River plus the storage in Lake St. Clair by 170 cubic feet per second.

During the period from June to November, inclusive, the

average run-off per square mile for the Lake Erie-St. Clair watersheds is 0.252 cubic feet per second, as shown in Table LXIXa of Williams' Exhibit 34. The area of the land watershed tributary to Lake St. Clair and the St. Clair below the Dry Dock Section is 5,691 square miles, by the report of the International Waterways Commission, whence there is to be expected an increase of discharge of the Detroit River over the St. Clair River of about 1,430 cubic feet per second. This quantity is reduced by the water abstracted by the Detroit Water Works that is used for the generation of steam and for lawn and street sprinkling, which does not find its way into the sewers. During 1901 and 1902, from an examination of the records of the pumping at the Detroit Water Works, this is estimated at about 15,000,000 gallons daily during the period of the gagings, which is about 230 cubic feet per second. The net result is that the Detroit River discharge should have been about 1,000 cubic feet per second greater than that of the St. Clair for the periods in question. The gagings of the Detroit River, therefore, disagree with those of the St. Clair by about 1,200 cubic feet per second, which is less than 0.6 of 1 per cent. The gagings of the St. Clair being reduced by the defendant's equations.

The Detroit measurements then afford a further check upon the accuracy of the St. Clair and St. Lawrence observations, and a further proof of the incorrectness of the Niagara results. As already shown in Table XXI of Exhibit 34, the annual fluctuations of Lake St. Clair are 89.4 per cent. of those of Lake Huron, and as the water contributed by the Lake St. Clair drainage is relatively insignificant, the increment of the Detroit must be 1 divided by 0.894, or 1.12 times that of the St. Clair.

As previously shown, the St. Clair increment is about 28,872 cubic feet per second, and that of the Detroit then is is about 32,300 cubic feet per second, or slightly more than the value of 32,000 previously predicted from the investigation of separate increments.

We, then, have the following equation referring back to the fact that the fluctuation of Erie is 0.956 that of St. Clair; S minus 32,300 plus 0.956 E equals Zero; that is the algebraic sum of the increments due to Lake St. Clair designated as S and Lake Erie designated as E must equal the net increment of the Detroit River; in which equation S is the increment due to Lake St. Clair and E that due to Lake Erie.

By a comparison of the monthly changes in mean eleva-

tion of Lake St. Clair and Erie for months when Lake Huron was at the same mean elevation as presented in Table LV, these observations being taken for the open season only as the presence of ice entirely nullifies the value of any such comparison, a rise of one foot in Lake Erie is accompanied by an average rise of .49 in Lake St. Clair.

A rise of 0.49 foot in Lake St. Clair will reduce the flow of the St. Clair River by 0.49 times 13,000, equals 6,370 cubic feet per second, since the increment of the St. Clair River due to the changes of Lake St. Clair is minus 13,000, as previously derived by the defendant and substantially the same figure being arrived at by the complainant, and since the inflow from the land areas to Lake St. Clair is not appreciably changed, the discharge of the Detroit River must be correspondingly reduced, whence it follows that 0.49 S plus 6,370 plus E must equal Zero, where S is as before the increment of the Detroit River due to changes in Lake St. Clair and E the increment due to changes in Lake Erie.

Solving these two equations for the values of S and E, we find that S equals 72,200 cubic feet per second, and E equals minus 41,750 cubic feet per second, or a rise of one foot in Lake St. Clair would increase the discharge of the Detroit River by 72,200 cubic feet per second, and the rise of one foot in Lake Erie would reduce the discharge of the Detroit River by 41,750 cubic feet per second.

At first sight, having in mind the increments of Huron and St. Clair for the St. Clair River, one is inclined to doubt the correctness of these values, but an examination of the characteristics of the two rivers makes it evident that with its shorter length, greater cross section and less slope, any change in either lake will produce a very much greater effect in the Detroit than in the St. Clair. This is also established by the fact that if, under average conditions, Lake Erie were suddenly to rise 2.61 feet, it would be at the same level as Lake St. Clair at Windmill Point and the flow of the Detroit River would be reduced to zero. It then follows that for this extreme variation the average increment of Lake Erie would be about 200,000 divided by minus 2.61, equals minus 76,500 cubic feet per second. On account of a steeper slope between Mamijuda Light and Lake Erie, this being the lower quarter of the river, the increment for the changes near the normal stage of Erie would be less than for those as the level of Lake St. Clair was approached.

Similarly if under ordinary conditions, by reason of ice jams in the St. Clair River and its local tributaries, the in-

flow to Lake St. Clair should be cut off and the lake should fall 2.61 feet at Windmill Point, it would be at the same level as Lake Erie, and the flow of the Detroit River would be again reduced to zero, in which case the average increment of Lake St. Clair would be 76,500.

As a combination of these conditions led to a reversal of flow of the Detroit River in February, 1896, there is nothing forced in these assumptions, and no reason appears for doubting the correctness of the increment of 72,200 cubic feet for Lake St. Clair and 41,750 cubic feet per second for Lake Erie above derived for average conditions.

Referring again to the results of the comparisons of discharges with Lake Erie constant and then with Lake St. Clair constant, if there be excluded from the former, those cases would show a decrease of discharge for a rise of St. Clair and an increase of discharge for a rise of Erie, both of which conditions are inconsistent with the laws of nature, the separate increment would be 81,300 for St. Clair and minus 38,720 for Erie. In other words, the two methods of derivation of an increment, even though the number of observations to be used is too limited to render the results certain, agree within certainly a fair range for observations of this kind.

For the purpose of some further comparisons, the discharge of the Detroit River will be computed for the average open season elevations from 1900 to 1907, inclusive, which will be designated as the reference condition. The purpose of using this period from 1900 to 1907, inclusive, is that it is the period most closely comparable with the conditions at the time of the gagings in 1901 and 1902, as since 1907 the presence of obstructions in connection with the Livingstone Channel, and later the opening of the channel itself, have caused a change of conditions in the river,which has made the flow to follow somewhat different laws since 1907 than it followed from 1900 to that date. During this period from 1900 to 1907, as shown by Williams' Exhibit 27, the mean elevation at Windmill Point was 575.13, and at Amherstburg, 572.65. The mean elevations during the gagings of the Detroit River were: Windmill Point, 574.99 and at Amherstburg 572.34.

During the month of July, 1902, there were 23 discharge measurements made at Ft. Wayne extending from the 1st to the 31st inclusive, no two being made the same day, and giving a mean of 204,506 cubic feet per second. These measurements must therefore represent fairly the average discharge of the Detroit River during that month.

The mean elevation at Harbor Beach for July, 1902, was

580.76, and the mean at St. Clair Flats was 575.76. The discharge of the St. Clair River of July, 1902, was by the defendant's equation 201,013 cubic feet per second. To this should be added the inflow from the Lake St. Clair drainage, which for the month of July has an average value of .3 cubic feet per second per square mile, and for 5.691 square miles would amount to 1,707 cubic feet per second.

The Detroit Water Works was abstracting about 230 cubic feet per second, as previously computed, and the rainfall exceeded the evaporation based on the Rochester Observations of evaporation, which are presented in table LXII of Williams' Exhibit 34, by about .25 of a foot. This is equivalent to a flow of 1,309 cubic feet. During the month, Lake St. Clair rose .27 of a foot, which represents a storage of 1,414 cubic feet per second. The expected discharge of the Detroit River would then be the discharge of the St. Clair as above quoted, 201,013 cubic feet per second, run-off from St. Clair drainage 1,707 cubic feet per second; excess of rain over evaporation on the lake surface, 1,309 cubic feet per second or 204,029 cubic feet per second less storage of 1,414 cubic feet per second and the use of water by the Detroit Water Works of 230 cubic feet per second, that being the water which does not reach the sewers, amounting to a total subtractive quantity of 1,614 cubic feet per second, leaving a net discharge for the Detroit River of 202,415 cubic feet per second. The measured discharge was 204,506 cubic feet per second, showing an excess of 2,091 cubic feet per second, or about 1 per cent. of the measured discharge. This may be almost wholly, if not wholly accounted for by the excess run-off over the average from the St. Clair drainage, as the rainfall for July, 1902, at Detroit was 4.19 inches, or more than 100 per cent. in excess of the normal which would be expected to increase the discharge or the inflow to Lake St. Clair by something in the neighborhood of 2,000 cubic feet per second.

This again shows a close agreement between the Detroit and St. Clair discharges when reasonably interpreted, and we may therefore use the conditions of July, 1902, to establish the reference discharge of the Detroit River for the period 1900 to 1907 inclusive. The elevation at Windmill Point for the reference period was .37 of a foot lower than it was during July, 1902. The elevation at Amherstburg was .66 of a foot lower than it was in July, 1902. The observed discharge of 204,506 cubic feet per second should then be reduced for the decreased height of Windmill Point by 0.37

times 72,200 or 26,700 cubic feet per second, and should be increased on account of low stage of Erie by .66 times 41,750, or by 27,555 cubic feet per second, making a net positive correction of approximately 800 cubic feet per second. The reference discharge then is 204,506 plus 800 equals in round numbers 205,300 cubic feet per second.

The mean dscharge of the St. Clair for the reference period by the defendant's equation is, as already stated, 197,163 cubic feet per second, and allowing 2,000 cubic feet per second as the net increase of discharge between the Dry Dock Section of the St. Clair and the Ft. Wayne Section of the Detroit, the difference between the two determinations of the reference discharge, the one based on the Detroit measurements directly and the other on the St. Clair observations, is 6,100 cubic feet per second, or about 3 per cent. of the average of the two determinations.

Q. By reference discharge there, you mean for a certain period?

A. That is the reference, I said I would call that period from 1900 to 1907 the reference period.

As the St. Clair discharge is based on the larger number of observations, it is entitled to the greater weight, and it is therefore concluded that the reference discharge of the Detroit River is about 199,000 cubic feet per second.

In the month of August, 1912, there was completed through the reefs at the foot of the Detroit River a new channel, 300 feet wide, having a navigable depth of 22 feet, where in places there were formerly only about four feet of water. In the construction of this channel, a considerable portion of the river was closed by a coffer dam from early in 1908 until the completion, and the material from the excavation was spoiled in the shoaler water on both sides of the work. Prior to the beginning of the work, no discharge measurements were ever attempted in that portion of the Detroit River, so far as it has been possible for me to learn. But during the construction, and since completion, several discharge measurements have been made.

The effect of the cofferdam prior to the completion of the work was to raise the level of the river above it, and also both Lake St. Clair and Lake Huron, as shown in table LXIII of Williams Exhibit 34, the slope from St. Clair to Erie being increased about 0.10 foot by the backwater raising the former, and Lake Huron would in time be raised about one-fourth as much. On the opening of the channel, the river very soon assumed its usual slope, and it becomes of interest

to ascertain whether the discharge under normal conditions of slope and stage will be greater or less than before the work commenced.

The river in the locality in question, as shown by Williams Exhibit 9, is divided by Grosse Isle into two channels. The Western or Trenton Channel being unaffected by the improvements except as they affect the slope between its two extremities, and the velocity and depth of the approaching water. Discharge measurements made in this channel on August 29th and 30th and December 5, 1912, after the opening of the Livingstone Channel, when reduced to the conditions corresponding to a normal determination by the mean stages of Lake St. Clair and Erie for the open season from 1900 to 1907, that is to our reference discharge as shown on charts 1, 2, and 3 of Williams Exhibit 34, gives a discharge of 35,818 cubic feet per second.

Mr. Wilkerson: Are those observations published?

A. They are published; I have blue prints here. Part of them are published and part are in the form of blue prints, which I got from the Government Office.

To the east of Grosse Isle as shown on Williams Exhibit 9 and to a larger scale on Williams Exhibit 10, entitled "Lower Detroit River," the river is divided again by a small island known as Stony Island, and the channel between it and Grosse Isle is designated as "Stony Island Channel." The discharge of this channel was measured on August 20 and 21 under conditions closely approximating the normal above adopted, that is the reference condition, and when these discharges are reduced to the reference condition as shown on chart 4 of Exhibit 34, the discharge becomes 11,203 cubic feet per second. The Livingstone Channel cofferdam extended eastward from Stony Island as shown on Williams Exhibit 10 to the so-called Lime Kiln or Amherstburg Channel, and the new cut opens through the middle of it, that is through the middle of the cofferdam. A discharge measurement was made on this channel December 17, 1912, when the conditions were not far from the reference conditions, when reduced to those conditions as shown on chart 5 gave a discharge of 37,400 cubic feet per second. Measurements made on the Lime Kiln Channel October 24, and December 18, 1912, when reduced to the reference conditions as shown on chart 6 give an average discharge of 106,098 cubic feet per second.

Combining the discharge of the several channels reduced to the condition of the river from 1900 to 1907, as indicated

by the mean stages of Lake St. Clair and Erie, we have: Trenton Channel, 35,818 cubic feet per second; Stony Island Channel, 11,203 cubic feet per second; Livingstone Channel, 37,400 cubic feet per second; Lime Kiln Channel, 106,098, making a total of 190,519 cubic feet per second.

The International Waterways Commission in the report on the regulation of Lake Erie for 1910, at page 102 give the discharge of the Detroit River for the several years from 1900 to 1907 from which the average is found to be 189,900 cubic feet per second. This result is out of harmony with that which is obtained from the Detroit gagings when the relation that the velocity varies as the square root of the hydraulic radius times the slope is applied to the whole series of the Detroit River gagings. Applying this well known relation, we have the mean fall from St. Clair flats to Lake Erie during the gagings was 575.36 minus 572.12 equals 3.24 feet. The mean elevation at Ft. Wayne was 574.20, or .2 of a foot below elevation 574.40 at which the area of the section is given in the report of the Chief of Engineers for 1903, page 2814, as 76,770 square feet; and from the cross section of the river at Ft. Wayne which is published in the report for 1902, opposite page 2870, the width appears to be about 2235 feet, although it is not marked.

The area of the section during the reference period then would be approximately 76,770 minus 0.2 times 2,235 or 76,323 square feet. The hydraulic radius was approximately 76,323 divided by 2,235 or 34.15. The mean velocity was 198,960 divided by 76,323 or 2.60 feet per second. The mean elevation of the Ft. Wayne gage for the open seasons of 1906 and 1907 was 574.596; that of St. Clair Flats was 575.675, and that of Lake Erie 572.635. The fall from St. Clair Flats to Ft. Wayne was 1.08 and to Erie 3.04. The fall to the former was therefore 35.5 per cent. of the latter. The mean elevations of St. Clair Flats and Lake Erie for the open seasons from 1900 to 1907 were 575.43 and 572.41 respectively, showing a fall of 3.02 feet. The fall to Ft. Wayne from St. Clair Flats would therefore be 0.355 times 3.02 equals 1.06 feet for the reference period, and the elevation at Ft. Wayne would be 575.43 minus 1.06 equals 574.37 or 0.03 less than 574.40 at which the area as above stated is given as 76,770 square feet. This reduces the area of the section by 0.03 times 2,235 equals 67 square feet or to 76,703 square feet. The hydraulic radius would be approximately 76,703 divided by 2,235 equals 34.32. The discharge for reference conditions then would be 76,703

times 2.60, times the square root of 34.32 divided by 34.15 times the square root of 3.02 divided by 3.04, which equals one finally, as it happens, the influence of the hydraulic radius almost cancelling the influence of the change in slope, so that our final result is 76,703 times 2.60 which equals 199,428 cubic feet per second, or substantially the same value obtained for the reference discharge by reference to the St. Clair discharge. This incidentally affords further evidence of the consistency of the St. Lawrence, St. Clair and Detroit measurements and the inconsistency of those at Niagara. It therefore appears that the net result of the Livingstone Channel work has been to decrease the discharge of that section of the Detroit River about 8,500 cubic feet per second, that is the difference between 199,000 cubic feet per second, the reference discharge for the period from 1900 to 1907, and 190,500 cubic feet per second, the discharge obtained by the summation of the separate discharges measured after the opening of the Livingstone Channel, which may be expected to ultimately raise Lake St. Clair about 1.4 inches, and Lake Huron about one-fourth as much. An increase in the width of the Livingstone Channel is contemplated from 300 feet as at present to 450 feet, and the excavation through the rock section included in the cofferdam has already been extended to the greater width. When the entire channel is increased to its width, this width, for the same stages of water above and below, the discharge will be increased by about 50 per cent.; or at normal stages by nearly 20,000 cubic feet per second, and if this be uncompensated it may be expected to lower Lake St. Clair something over three inches, or somewhere about three inches, and Lake Huron by an amount corresponding to a diversion of about 3,000 cubic feet per second at Chicago.

Q. That is according to the deductions from the discharge measurements?

A. Deductions from the measurements made by the complainants.

I will now call attention to table LXIII of Exhibit 34 entitled "The effect of the Livingstone Channel." The first column represents the year upon which the information is based. The comparisons have been made with October, November and December only, for the reason that the Livingstone Channel was opened in September, and no observations covering the other months were available to us at the time this table was prepared; so that we were forced to make the compari-

son with the last three months in the year. And it will be noticed that in 1909, the December elevations have been omitted. That is for the reason that during December, 1909, there was an ice gorge in the Detroit River which caused conditions to be entirely unnatural and therefore we were forced to reject December, 1909, and base the average for that year on the two months of October and November.

The fifth column gives the mean elevation for the months of October, November and December for each year. The sixth column gives the fall from Lake Huron to Lake St. Clair. Columns 2, 3 and 4 give the elevations of Lake Huron at Harbor Beach. Column 5 gives the mean elevation. Column six gives the fall from Harbor Beach to St. Clair Flats. Columns seven, eight and nine give the elevation of St. Clair Flats for October, November and December. Column ten gives the mean elevation. Column 11 gives the fall from St. Clair Flats to Erie, and columns 12, 13 and 14 give the elevation of Lake Erie for October, November and December.

Column 16 gives the mean elevation of Lake Erie for the three months, and the last column gives the fall from Huron to Erie.

It will be seen that during the period 1900 to 1907, the mean elevation of Lake Huron was 580.63; the fall from Huron to St. Clair was 5.41 feet; the mean elevation of St. Clair Flats was 575.22. The fall from St. Clair to Erie was 3.28 feet. The mean elevation of Erie was 571.94 and the fall from Huron to Erie was 8.69, so that the fall from Huron to St. Clair was 62.2 per cent. and the fall from St. Clair to Erie was 37.8 per cent. of the fall from Huron to Erie.

For the conditions from 1908 to 1911 inclusive, or during the construction of the Livingstone Channel, the average fall from Huron to St. Clair was 59.2 per cent. and from St. Clair to Erie was 40.5 per cent. of the fall from Huron to Erie. For the three months of 1912 after the opening of the Livingstone Channel, the fall from Huron to St. Clair was 61.2 per cent., or within one per cent. of what it was during the period from 1900 to 1907, and the fall from St. Clair to Erie was 38.8, or again within one per cent. of what it was during the previous period, and the elevations were as indicated in the line opposite 1912.

A summary of the results is presented at the bottom of the table headed "Changes in feet" whence it appears that from the conditions of 1900 to 1907 and the conditions of 1908 to 1911 Huron fell 0.62, St. Clair fell 0.21 and Erie fell 0.34.

The slope from Huron to St. Clair was reduced 0.41; from St. Clair to Erie the slope was increased 0.13 and from Huron to Erie the slope was decreased 0.28.

Comparing 1908 to 1911 with 1912, the elevation of Huron increased 0.41, St. Clair increased 0.18 and Erie increased 0.27.

The fall from Huron to St. Clair was increased 0.23; from St. Clair to Erie was decreased 0.09 and the fall from Huron to Erie was increased 0.14.

Comparing the period 1900 to 1907 with 1912, we find that the elevation of Lake Huron was decreased 0.21, St. Clair was decreased 0.03 and Erie 0.07. The fall from Huron to St. Clair was decreased 0.18, from St. Clair to Erie was increased 0.04, and the fall from Huron to Erie was decreased 0.14.

To interpret the indication from this table, it is that the opening of the Livingstone Channel restored very nearly the conditions which existed prior to the obstruction of the river during its construction; the slopes in the two rivers, the St. Clair and the Detroit, being returned to within one per cent. of the relations which they occupied to the whole slope prior to these constructions.

Q. Since the date of the taking of the testimony at the last hearing, have you prepared any further tables to be added to Exhibit 34?

A. Yes.

Q. Will you state what they are?

A. As a result of inquiries which were made at the previous hearing, certain tables have been added for the information of the complainant, and also other tables to be used in connection with the testimony just given and to follow have been appended; and by agreement they are incorporated as a part of Williams Exhibit 34, and will now be identified.

The first table that has been introduced is table XVIII a, which is a table showing the elevations of Lakes Huron, St. Clair and Erie and the falls between the several lakes for the closed season, December to March inclusive, from 1861 to 1912. The arrangement of this table is similar to that of table XVIII, which gives similar data for the open season, and to table XIX, which gives similar data for the full year. They are based upon the records furnished by the United States Lake Survey and presented as Williams Exhibit 26.

The next table that has been introduced is table XLV a, consisting of five sheets, and shows the preliminary computa-

tions for the discharge of the Niagara River referred to the Buffalo gage, which were summarized in table XLV previously. This table has been introduced at the request of the complainant, and a copy of it previously furnished.

The next table in question that has been added is table XLVI a, which is a recomputation of the increment of the Niagara River when referred to the mean elevation of the Buffalo and Amherstburg gages. It was found that in the computations of table XLVI, the method of weighting the observations was slightly different from that which had been used in the other computations; that is instead of distributing each gaging over the period covering half the elapsed time between the preceding and following gaging, they had been simply taken as the average of the days in question; and in order that the tables might be on the same basis, although we lay no particular stress upon them, we recomputed and have added this table XLVI a, which shows what the increment based upon the Buffalo and Amherstburg mean daily records would be, if those observations were treated in exactly the same way that the Buffalo observations are treated in table XLV.

It will be noticed that the change in the increment due to this change in the method of weighting is inconsiderable.

The next table, table XLVI b, is an increment for the Niagara River derived by reference to the Amherstburg gage, being treated in the same manner as the Buffalo gage in table XLV, and the Buffalo and Amherstburg in table XLVI a.

This is interesting as showing an increment for Lake Erie when referred to the Amherstburg gage of 47,217 cubic feet per second.

The next table that has been introduced is table XLVII a, which bears the same relation to table XLVII that table XLVI a bears to table XLVI. That is it was found that in computing table XLVII, the observations had been simply averaged for the period covered, instead of distributed with reference to the time elapsing between them and table XLVII a then represents the increment computed in a manner entirely analogous to that computed for the Buffalo gage in table XLV. The increment as obtained here is 33,590 as compared with 32,060 in the previous one.

Q. That is the Niagara River?

A. That is the increment for the Niagara River referred to the Cleveland gage; and by this computation, which is analagous to that used for the Buffalo gage is 33,590, whereas

by the other method of weighting the individual observations, it is 32,060.

Table XLVIII-a gives the annual precipitation at various stations on the Great Lakes, and comprises three sheets. This table was previously summarized in table XLVIII, but the entire data is presented for such reference as may be desired.

Table LV is the next table, and that follows table LIV and shows the relative fluctuations of Lake St. Clair and Erie during the open season, April to November inclusive; these fluctuations being based upon the changes of elevations with Lake Huron at constant or practically constant elevations.

In other words it was to establish the relation between St. Clair and Erie independent of changes of Lake Huron; and results in the relation that the change of Lake St. Clair when Lake Huron remains at a constant elevation is 49 per cent. of the change of Lake Erie.

Table LVI gives winter temperatures, that is the closed season from December to March inclusive, at Detroit, Buffalo and Oswego for the period from 1889 to 1912.

Table LVII is a table of drainage areas of the Great Lakes and is based upon the report of the International Waterways Commission. The first column gives the names of the rivers. The second column of this table gives the total drainage area tributary to the river in question in both land and lake.

The third column gives the total area of lake surface in the drainage, and the fourth column gives the total land area. The fifth column gives the local land and lake area; that is that of the particular river in question, or between that river and the one next following. The sixth column gives the local lake area. The seventh column gives the local land area.

The last column in the table gives the amount in cubic feet per second which would be represented by a run-off of one inch per year on the local lake surfaces.

Table LVIII gives a comparison of the river discharges; the first column giving the names of the rivers; the second and third column giving the discharges; the second column being the total discharge of the river and the third column being the discharge of the river less the discharge of the river next upstream; in other words being the local discharge.

This information is here given as derived by the complainant's equation for the period from 1900 to 1907, as presented in the report of E. S. Wheeler for 1882 to 1898, in the report of the Chief of Engineers for 1903, and as reported by the

International Waterways Commission, in their report on the regulation of Lake Erie for 1910, covering the period from 1890 to 1904, that is winter and summer.

The fifth and sixth columns give the run-off per square mile, the fifth being the total land and lake surfaces and the sixth column the total land surfaces.

The seventh and eighth columns give the local run-offs per square mile; the seventh column being for land and lake surfaces; the eighth column for land surfaces alone.

The last column represents the run-off per square mile in cubic feet per second of the streams that have been gaged upon the several watersheds.

Table LXIX-a gives a summary of the observations of run-off from the several drainage basins of the Great Lakes for each month in the year covering the basins of Huron, Michigan, Erie, St. Clair and Ontario; also for the full year for the open season April to November inclusive, and for the period June to November inclusive.

From this table it appears that the average run-off per square mile for the full year from the Huron-Michigan drainage area is 0.866 cubic feet per second; for the St. Clair-Erie drainage area 0.664 cubic feet per second, and for the Ontario drainage area 1.440. For the open season period from April to November inclusive, for the Huron-Michigan drainage, the average run-off is 0.844; for Erie 0.415; for Ontario 1.339. For the June to November period inclusive, the average run-off from the Huron-Michigan area is 0.640; for the St. Clair area 0.252, and for the Ontario area 0.924.

Table LXIX-B presents in detail the run-off from the Huron-Michigan drainage areas by months, and represents the method of computing the run-off as summarized in the preceding table. This method was to take the total discharges that were observed in each month and divide by the total areas which were represented by those discharges so that the average all the time is the average discharge of the entire area on which observations were available.

Table LXIX-c gives the similar information for the Lake Michigan drainage alone, and shows the rivers upon which the gagings were taken and the years over which the gagings extended, and also the months in the years which the gagings actually covered. This is composed of 14 sheets.

Table LXIX-d gives similarly the run-off from the Lake Huron drainage; and is composed of five sheets.

Table LXIX-e gives similarly the run-off from the Lake Erie drainage, and is composed of seven sheets.

Table LXIX-f gives the similar information, the run-off from the Lake Ontario drainage, and is composed of 11 sheets.

Table LX-a, composed of two sheets, gives the summary of the rainfall upon the drainage areas of Huron-Michigan, Erie and Ontario respectively from 1900 to 1904, by months and also for the full year, the April to November period and the June to November period.

Table LX-b, composed of five sheets, gives in detail the precipitation on Lakes Huron and Michigan for the period from 1900 to 1904 inclusive.

Table LX-c, composed of 3 sheets, gives similar information as to precipitation on the Lake Erie drainage area.

Table LX-d, of three sheets, gives similar information for the Lake Ontario drainage area. These tables have been compiled from the published records of the United States Weather Bureau.

Table LXI-a gives the summary of the mean temperatures observed by various observers on the Great Lakes. The two sources of information are the reports of the City Water Works at Chicago and Milwaukee on Lake Michigan, and Detroit on Lake St. Clair, at Cleveland on Lake Erie and at Toronto on Lake Ontario; and also the records of the United States Lake Survey give temperatures taken at various light houses and light ships on the several lakes and cover Lake Michigan, Lake Huron, Lake St. Clair, Lake Erie and Lake Ontario. This table is composed of two sheets.

Table LXI-b, embracing five sheets, gives in detail the temperatures of lake water and of air at the several water works, pumping stations just referred to; being those at Chicago, Milwaukee, Detroit, Cleveland and Toronto.

Table LXI-c gives the information obtained from the United States Lake Survey of temperature observations of air and water at various light house and light ship stations on the Great Lakes; it embraces six sheets.

Table LXI-d gives surface water temperatures observed by representatives of the United States Lake Survey from boats in passing through Lakes Superior, Michigan, Huron, the St. Clair River, Lake St. Clair, Detroit River and Lake Erie, and covers five sheets.

Table LXII gives the meteorological records at Rochester as published in the annual report of the Board of Public Works of Rochester for 1907, which is the last report that has been printed. It shows records of evaporation from a tub floating in the Mt. Hope reservoir, and also from a tub above

the water, mounted on a raft about 30 inches above the water's surface.

The table presents in its first column the years in question; in the second column the month. The third column gives the evaporation from the exposed tub, being the one mounted about 30 inches above the water's surface of the reservoir. The fourth column, the evaporation in inches from the tub floating in the reservoir and filled with water substantially to the level of the water outside it.

The fifth column gives the temperature of the water in the exposed tub in degrees Fahrenheit. And the sixth column gives the temperature of water in the floating tub, in degrees Fahrenheit.

The seventh column gives the temperature of the water in the reservoir at the same time in degrees Fahrenheit and the eighth column gives the temperature of air in the shade, in the vicinity of the tub. And the last column gives the precipitation in inches observed at the Mt. Hope reservoir.

In the lower half of the table is given the records at the United States Weather Bureau's station at Rochester; the first column representing the years; the second column the month; the third column the precipitation in inches; the fourth column the normal precipitation or the mean precipitation for that month since 1870. The fifth column, the mean temperature for the month in question. The sixth column, the normal temperature for that month, or the mean since 1890. The seventh column, the mean humidity during the month in question, and the last column the normal humidity or the average since 1870.

This table is of interest in connection with estimates of the evaporation from the lake surfaces, and constitutes the most extensive observations upon the evaporation from water surfaces that have been made anywhere in the world, so far as an extended investigation of the authorities on the subject reveal.

Table LXIII has already been described, being the table referring to the effect of the Livingstone Channel.

Table LXIV shows a comparison of results obtained with the Haskell meter at the Hydraulic Laboratory of Cornell University, when the rating was made by moving the meter at a regular speed through the water, and when a rating was made by moving the same meter under similar conditions at irregular speeds through the water.

This table will be discussed further.

Q. By whom were those observations made?

A. The observations were made by myself.

Q. Table LXV shows the average elevation of Lakes Michigan, Huron, St. Clair and Erie for each of ten years, and for the ten years preceding the opening of the Chicago Drainage Canal; and also the average elevation of the same lakes for each of the ten years immediately succeeding the opening of the Drainage Canal; and the mean for the period of ten years.

Q. One for the period immediately preceding, and one immediately following?

A. And the one for the period immediately following.

Chart 1 shows the computations involved in the reductions of the observations of discharge of the Detroit River in the vicinity of the Livingstone Channel, to reduce them to the reference condition of average lake elevations 1900 to 1907.

Q. Charts 1, 2 and 3 refer particularly to the Trenton Channel?

Q. Those are charts. We did not have charts before?

A. No, we did not have charts before. Chart 4 refers to the Stony Island Channel; chart 5 to the Livingstone Channel, chart 6 to the Lime Kiln Channel.

Plate 9 has been added, which shows the cross sections of the St. Clair River, the Niagara River, Bridge Section, Niagara River Open Section, St. Lawrence River and the Sanitary District Canal, all drawn to the same scale; the relations between the horizontal and vertical sections being natural.

The scale is: One inch equals 250 feet; the cross sections for the several rivers being taken from the reports of the Chief of Engineers of the United States army, as presented in connection with the gagings of the several rivers. The section of the Drainage Canal is the rock section, which has the largest carrying capacity of any portion of the channel.

Plate 10 is a profile of the St. Clair and Detroit Rivers and Lake St. Clair, being based upon the profile published in the report of the United States Deep Waterways Commission, and corrected for the recent deepening of channels and changes in water surface. The solid areas, first at the foot of Lake Huron, then at the head and foot of Lake St. Clair and finally at the foot of the Detroit River, represent the material that has been removed and the increased depth of channel that has taken place in those localities as a result of the Government's improvements of navigation. That is the solid white as distinguished from the cross hatching representing

the bottom of the stream. This is of course distorted; the scale being as indicated in miles at the bottom, and as indicated in feet along the left hand side of the plate; but it is an exact copy except for cutting deeper to the present depth of channel.

Recess to 2:30 p. m.

After recess, 2:30 p. m.

GARDNER S. WILLIAMS resumed the stand and testified further as follows:

Mr. Adcock: Now you have those tables before you?

A. Yes, sir.

Q. Ready to substitute them?

A. To substitute these in place of Exhibit 34.

Mr. Adcock: I submit to the Commissioner a number of sheets and offer them in evidence as Williams Exhibit 35, consisting of 18 sheets, designated as charts 1, 2, 3, 4 and 5; chart 1 consisting of five sheets; chart 2, one sheet; chart 3, consisting of four sheets; chart 4, six sheets, and chart 5, two sheets.

(Whereupon the charts so submitted to the Commissioner were marked Williams Exhibit 35.)

Q. Mr. Williams, will you describe the exhibit that has just been identified?

A. This exhibit consists of five charts numbered from 1 to 5. Chart 1 consists of five sheets and is a plotting of the gage elevations of Lake Huron at Harbor Beach, and Lake St. Clair at St. Clair Flats, covering the periods during which gagings were in progress on the St. Clair River and somewhat antecedent thereto. There is indicated on these charts in numbers the discharge found on the respective days when gagings took place. There is further indicated by arrows on this chart the periods which were included in the preparation of table 28 of Williams Exhibit 34. This chart 1 represents the gagings of 1899 to 1902 inclusive.

Chart 2 gives similar information for the gagings of the St. Clair River for 1908, 1909 to 1910 inclusive, and the periods indicated by the arrows and the Roman numerals correspond to those in table 34 of Williams Exhibit 34.

Chart 3, consisting of four sheets, gives similar information as to the elevation of Lake Erie at Cleveland during the

gagings, and the periods represented are those of table XLVII.

Chart 4, consisting of six sheets, gives similar information as to the elevation of Lake Erie at Buffalo, and the periods are those indicated in table XLV-a of Williams Exhibit 34.

Chart 5, comprising two sheets, represents the similar information for the St. Lawrence gagings, gage heights both at Ogdensburg and Oswego being plotted. The periods are those used in table XLI of Exhibit 34.

These plottings show, of course, the daily indicated fluctuations of the lake levels during the periods covered by them, and are noticeable as indicating that during the earlier gagings of the St. Clair, Lake St. Clair was apparently at a uniform elevation in some cases for as much as three weeks, which is, of course, a physical impossibility, as the elevation of the lake changes from day to day. The only reasonable inference to draw is that the gage reader did not read the gage, but simple put down from day to day the same reading that the gage had at some time when he did read it; and, of course, the resultant inaccuracies of gage reading must be reflected in any deductions of discharge, in which those gage readings play a part. If the readings of Lake St. Clair for the period of June, 1899, for instance, be compared with those of June and July, 1910, shown on Chart 2, sheet 6, the impossibility of the condition appearing in chart 1 must be evident.

Q. From the examination which you have made and the facts and data which you have heretofore presented in evidence, and your investigations of the discharge measurements of the various rivers under consideration, the St. Clair, the Detroit, Niagara and St. Lawrence Rivers, and the relative sizes of the drainage areas, will you state what conclusions if any you have reached with reference to the accuracy or possible inaccuracy of the discharge measurements of those rivers made by the Lake Survey?

A. In beginning to answer this question, I would like to repeat what I said earlier in my testimony, that so far as the work done by the Lake Survey parties in the field, so far as the possibility of accomplishment with the means at their hands is concerned, I think that they did a most remarkably creditable piece of work.

The criticisms which I have to make upon it are criticisms that to a large extent are at present beyond the power of man to remedy.

The gagings of the St. Lawrence, Detroit and St. Clair Rivers when considered with the variations of the elevations of the lake surfaces show a remarkable agreement, and indicate that whatever errors exist in the observations are of similar magnitude in all. As to the absolute accuracy of any of the measurements, there is no means of determination except the consistency of the observations themselves; and they all might easily be in error as much as ten per cent. On account of the size of the rivers involved, there is no possibility of making a comparison of this method of measurement with any other method of measurement.

Q. You are referring to the methods used and described heretofore?

A. Yes, in making a comparison of the methods of measurement used by the Lake Survey with any other method of measurement. So the accuracy of the observations are dependent: First, upon the accuracy of the reading of the meters; second, upon the consistency with which the meters retain their rating during the periods of observation. Third, upon the extent to which the position observed in the cross sections of the stream are representative of the flow in other parts of the stream. Fourth, as to whether the index velocities are always in the same ratio to the vertical and horizontal curves which they are supposed to represent.

And, fifth, as to whether it is possible to connect the discharge of any of these rivers at any particular time with any particular elevation of the Lake Surface.

The fact that at all of these gaging stations the discharge was actually affected, with possibly a single exception, by the elevation of a body of water below as well as above the gaging station, whose elevation, though dependent in a measure upon that of the water above, does not fluctuate with it according to a continuous law, and owing to the fact that any influence must travel from one lake to another before its full effect can be measured at any point between, all these make the possibility of accurate measurements extremely doubtful.

In a considerable experience with current meters and comparisons of their discharge with that of weirs, it has never been possible to get the two to agree within less than about 2 per cent., and differences of 10 to 20 per cent. have not been infrequent. I am speaking now of my own experience.

A long series of comparisons were made at the Hydraulic Laboratory of Cornell University by the New York State Barge Canal Survey, and are reported in the "Barge Canal

Report'' of the New York State Engineer for 1901, pages 932 to 951.

In these experiments, the current meters usually underregistered about 3 per cent., the situation being one where the conditions were extremely favorable for accurate meter work, in that the channel was rectangular, and it was possible to determine the area of the cross section with great accuracy and also to locate the position of the meter.

The meters were handled from rigid rods and were not allowed to drift upon lines or be dependent upon weights to maintain them in position. Moreover, the water was sufficiently clear so that the observer could see the position of the meter and visually observe whether it was operating in a rational manner or not.

In the rating of a pair of current meters for the Lake Superior Power Company in 1900, the effect of moving the meter through the water at speeds varying from point to point was investigated to determine the influence of the pulsations ordinarily felt in the lower parts of all large streams.

The meter was suspended on a rod from a truck which ran upon tracks spanning the canal.

The canal at the laboratory is 16 feet wide between side walls which are vertical and approximately 10 feet deep and about 30 feet in length.

The truck was built of wood and was propelled by hand at that time, as they had not yet installed the electric apparatus for driving the truck. A crew of men was employed to push the truck along the track, and the distance was taken by trips, forming an electric contact, at 10 feet intervals along the rail, and communicated by a chronograph to a sheet of paper.

The revolutions of the meter were similarly taken by the chronograph and the time was taken from a chronometer, all records being taken electrically, so that there was no step with which human agency was involved in getting the record of revolutions, velocity and time.

In the regular readings of the meter, the car was propelled at as nearly a uniform rate as was possible throughout the full length of the course, and the ratio between the revolutions of the meter and the velocity of propulsion recorded. Later it was suggested it would be interesting to ascertain what would be the effect on the meter if instead of being propelled at a uniform rate, the car would be propelled at an intermittent rate; that is to say, if a car were given a shove and then allowed to slacken its speed as the result of friction, and then

given another shove so as to give it a jerky or pulsating motion.

This method of rating was then carried out, so far as it was possible to do so with the apparatus. You will see at once that as high speeds were reached, it was impossible to give very many pulsations in going over the course, as the men could not accelerate the car to a velocity much beyond its average velocity.

The result of these observations are presented in table LXIV. In the left hand side of the table are the observations at a regular velocity. I may say that the observations presented in these tables were made with a Haskell Current Meter, which was owned by the Michigan-Lake Superior Power Company. It was similar in every respect to those which were being used by the United States Lake Survey at the same time. These observations were made in, I think, 1899.

Q. Were they made by you personally?

A. They were made by me. I was assisted in these observations by Mr. J. A. Vogleson, who is now the chief of the Bureau of Health of Philadelphia. He had at that time just been graduated from Cornell University, and was going to the Soo to assist in discharge measurements which the Lake Superior Power Company contemplated making on the St. Marys River at that time.

The first column of the table gives the group of observations.

The second column gives the number as they appear in the note books, each observation being numbered.

The third column gives the revolutions observed during each observation and the fourth column gives the velocity. The fifth column gives the ratio of the velocity to the revolutions.

In the right hand half of the table is presented similar information for the ratings at the irregular speeds.

Column 6, again, gives the number of the observations as found in the note book; column 7, the revolutions observed; colnmn 8, the observed velocity, and column 9, the ratio of the velocity to the revolutions.

It will be observed in comparing columns 5 and 9, that while at a velocity of about two feet a second the ratio of velocity to revolutions is practically the same for both the regular and irregular rating, that as the speed increases the number of revolutions corresponding—or rather the velocity corresponding to a given number of revolutions, increases in the case of the irregular rating over the similar ratio for the regular rating. So that at a velocity in the neighborhood of three feet

per second, the meter was under registering about 4 per cent. on the regular rating.

When the velocity had gotten up to between $3\frac{1}{2}$ and $3\frac{3}{4}$, the meter was under registering about 6 per cent. Beyond that it was, as I said, impossible to maintain the irregularity of speed to the same degree as was obtained at the lower velocities, so that by the time a velocity of four feet was reached, the under registration amounted to only about 3 per cent., and by the time a velocity of six feet was reached, the variable or irregular impulses practically integrated into a regular impulse, and the ratio comes back to the same figure.

These experiments showed that when moved through the water at irregular speeds, if the instrument be free to turn about both its axes, the Haskell Meter will under-register as much as 6 per cent. and very probably more at higher velocities.

These observations afford an explanation of the disagreement of the Niagara gagings with the others, as at the Niagara the current is much more disturbed and irregular than at any of the other stations. Eddies and whorles are constantly appearing at the surface, and so pronounced that they can be seen in crossing the International Bridge on the cars, and if this turmoil appears at the surface, we perhaps can imagine to some extent what it must be down in the depths of the river, where the agitation starts.

The condition is very well expressed in the language of Mr. F. C. Shenehon, in his report upon the gaging of the Niagara, in the report of the Chief of Engineers for 1900, page 5342, where he says:

"In such a section as that at the International Bridge, the proper derivation of the velocity co-efficient is the most difficult part of the river gaging. To obtain it, the writhing mass of waters streaming through the bridge openings and eddying about the piers, spurting and lagging in minor pulsations, speeding faster as the lake rises and flowing leisurely in low stages must be congealed to a solid by some instantaneous method of survey, and its dimensions taken."

It is not difficult to conceive of one of these eddies catching the tail of the meter and whirling it around at right angles to the direction of the main current.

Q. Will you describe the Haskell Meter somewhat in detail, so that we can get some idea of how it operates in the water?

A. The Haskell Meter consists of a shaft upon one end of which, the front end, is a wheel shaped similar to a propeller

wheel, so that the current as it comes towards the meter striking the blades of this propeller causes it to revolve. As it revolves, a contact is made and broken with an electrical recording or sounding apparatus, so that each revolution is transmitted to the recording device in the hands of the observer.

At the other end of this shaft, there is a vane or tail, which keeps the meter pointed upstream, or is intended to keep it pointed upstream, and in a reasonably straight current does so.

The meter is supported a short distance back of the propeller, and is allowed to vibrate, or to rotate both in the horizontal plane and in the vertical plane so that it may assume a position parallel to the direction of flow whichever way that may come.

The length of the ordinary Haskell meter from tip to tip is about 30 inches. I am speaking from memory, and I have not measured one in a long while. The direction meter is about 3½ feet long. I should say it was between 30 and 36 inches.

The point that I have in mind in connection with these eddies is that it is entirely possible that the head of that meter might be in a current that was moving fairly straight, while the tail of it was caught by an eddy and whirled around so that the wheel no longer pointed against the current, but might be in an angle away from parallelism with the directions of flow; and if it does not point in the direction of flow then its revolutions will be less for the same current than they would be if it pointed directly towards the oncoming current.

Q. I take it the Haskell meter is not unlike the weather vane that we sometimes see built by boys, a toy with a wheel revolving at right angles to the plane?

A. The same principle is involved, exactly. Of course, the Haskell meter is a more delicate instrument and more strongly built, being designed to resist the flow of moving water. And I may say that it is an exceptionally creditable instrument to its designer, but like other instruments it cannot be expected to perform impossibilities.

Q. Your idea is that as this meter is suspended in the water, the eddies may cause the tail to turn around at right angles to the regular current, or the way the river is flowing?

A. It is entirely possible that it might turn it as much as at right angles.

Q. Or pretty near so?

A. Or pretty near so.

Q. That would reduce the rotation of the wheel?

A. That would reduce the rotation of the wheel, while the quantity of water passing would not be changed.

Q. And would thereby register inaccurately?

A. And would thereby under-register.

Q. That motion might be horizontal—

A. Or vertical.

Q. —or vertical, or any other way?

A. Or any other way.

Q. According to the conditions of the water?

A. There is always of course the possibility of some obstruction getting upon the meter, which may remain for a short time and then be washed off, as floating grass or string, or even grit and sediment in the water will oftentimes cause a meter to change its rating in a comparatively short time.

The meter being suspended on a cable a long distance below the surface, out of sight, where the only indication that the observer could have of the performance of the meter was the record on the recording apparatus, and possibly the feel of the line, makes it practically impossible for him to tell whether the meter is pointing upstream or in any other direction.

There is a special attachment for the Haskell meter which indicates the direction in which it is pointing; but if the direction current meter was used at all it was only used at certain stations, and not for all the observation.

On the St. Clair, the direction current meter was used in combination with the other meters to give an indication of the direction of the current at certain points in the vertical; but it is a much more complicated machine to use, more liable to get out of order and consequently adds to the trials and tribulations of the observer. I speak from experience.

Q. You have spoken of the difficulties encountered in the use of the current meter in the Niagara River. Do the conditions there compare, are they similar to conditions in the St. Clair and St. Lawrence Rivers?

A. The conditions at the Niagara are very much worse than those encountered on the other rivers. The pulsation of the water in open channels, or in our rivers, is practically always present. I have observed it personally in the Detroit River in the vicinity of Belle Isle, both in current meter work and Pitot tube work, which I have had in the river, where the current will apparently run swiftly for a few seconds and then there will be a perceptible slowing down

for a few seconds, and then again a pulsation which will accellerate it again.

These pulsations were the subject of an extended discussion some years ago before the American Society of Civil Engineers, in which their presence in the St. Clair, the St. Marys River and the Detroit River were referred to by Mr. D. Farr and Henry, as a result of his experience in connection with the original Lake Survey current meter measurements.

Mr. Wilkerson: Have you a reference to the book?

A. I am speaking from memory on it, but the reference is to the discussion of a paper by Emil Kuichling on the resistance of a 24 inch stop valve. I think it is along about 1892. So that the other stations are undoubtedly affected similarly, but to a less degree, and all the gagings may therefore safely be assumed to be less than the true discharge.

Mr. Adcock: Q. Would that affect the determination of the increment?

A. Yes, the increment would be decreased in the same ratio as the discharge itself were decreased, assuming the error in discharge to be the same at different elevations; that is assuming the percentage error of discharge to be the same at different elevations.

To further examine the accuracy of the Haskell meter indications in disturbed water, a series of experiments were arranged for at the Hydraulic Laboratory of Cornell University, wherein the water was measured over a weir, and also simultaneously by a Haskell meter at various points along the experimental canal under varying conditions of disturbance. The meter used was one belonging to Cornell University.

The work was done by Professor E. W. Schoder, in charge of the laboratory, and Professor K. B. Turner, formerly junior engineer in the United States Lake Survey.

The arrangements were made with the kind permission of the dean of the College of Civil Engineering, Professor E. E. Haskell, the inventor of the Haskell meter, to whom I explained the purpose of the investigations and the scope which we hoped to have it cover.

Q. When were these made?

A. They were made during June and July.

Q. Of this year?

A. Of this year; better say during May and June of this year. I am not certain whether they ran over into July or not. My impression is they were all finished during June.

In these experiments, the data of which will be presented later in this case, the meter was found to register from 3 to 10 per cent. too low, depending on the disturbances of the water, although the conditions for accurate measurement were very good.

An error of 6 per cent. in the Niagara gaging would amount to about 12,000 cubic feet per second, and would about account for the discrepancy in the Niagara comparisons with the other three rivers. That such an error exists seems to be certain, for all the information on evaporation from lake surfaces and as to the surface temperatures of the Great Lakes, data upon which are presented in tables LXa to LXII inclusive, disprove the possibility of such evaporation as has been shown to be necessary to account for the small discharge of the Niagara River shown by Complainant's gagings.

Q. Am I correct in understanding this: That the disturbances in the Niagara River are so much greater than those in the St. Clair and St. Lawrence Rivers that you would expect that the meter would under register 6 per cent.

A. More than it does in the others.

Q. More than it does in the other two rivers, is that right?

A. That is the point, that the error is 6 per cent. greater there than it is elsewhere.

Mr. Wilkerson: I do not just get the basis for that 6 per cent. yet, as that answer now stands. Just explain that.

Mr. Adcock: That is my understanding.

Mr. Wilkerson: Yes.

A. In our first experiments at Cornell with the truck, we found at a velocity around three feet per second the meter under registered about 6 per cent. The velocities at Niagara were above three feet per second in general, so that I would expect a somewhat larger under-registration in those observations.

I think I am correct in making that statement of three feet, Mr. Shenehon. If I am in error, will you kindly correct me?

Mr. Shenehon: They are above three feet per second; fully as high as five.

The Witness: For that reason, I would expect the under-registration to be greater than 6 per cent.

Again, the experiments in the actually disturbed water in the canal at Cornell University showed discrepancies as high as 10 per cent., so that it seemed to be quite reasonable to suppose it possible that an error of 6 per cent. could have occurred in the Niagara gagings. That is all there is of it.

Mr. Wilkerson: I understand the point of this to be that if you increase the Niagara measurements 6 per cent. that brings St. Clair, Niagara and Detroit into harmony?

A. Yes.

Q. It makes them consistent, if you increase the Niagara 6 per cent.?

A. Yes, as far as discharge is concerned.

Mr. Adcock: As far as the records of the discharge are concerned?

A. Yes, as far as the recorded discharge, as far as recording the discharges are concerned, they become consistent.

Q. But still you would expect the measurements of the St. Clair and the St. Lawrence to be low under the current meter gaging?

A. I think it is entirely probable. I feel satisfied they are somewhat low.

Mr. Wilkerson: Your point is, if you increase the discharge 6 per cent., you would increase the increment 6 per cent.?

A. No, the increment is an entirely separate thing in this case, because as far as the increment derived for the Niagara River is concerned from the gagings, I consider it absolutely worthless. The relation between lake stage and discharge there is so variable that I think it is absolutely impossible to tie the discharge to the lake stage at the Niagara, the fluctuations are so sudden.

Q. Then I still do not get the point to your 6 per cent.

A. The 6 per cent. is that while it may be possible to measure the discharge of the Niagara River accurately at any particular time, or with a certain degree of accuracy, I will say, my conclusion is that whatever the error is on the others it is 6 per cent. greater at Niagara—or, I will not say that is my conclusion, but I say that if the error at Niagara be 6 per cent. greater than it is in the other measurements, then the Niagara gaging becomes consistent with the other gagings.

But when you talk of increment, that is another proposition entirely, because the increment is dependent upon the measurement of a stage in the lake and the masurement of discharge. Both may be correct, but they may not be the ones that correspond to each other; and with Lake Erie changing position as rapidly as it does, it is impossible that the full effect of any change could be transmitted to the gaging station before the lake had assumed some other position. Therefore I say it is impossible to connect the discharge accurately

with the lake stage, and hence it is impossible to get a correct increment of the Niagara River.

Q. That is your point, that you cannot get the correct increment of the Niagara from measurements there?

A. That is it.

Q. You have to work it either backward or forward?

A. That is my point. There may be some other way of getting it, but you can't get it the way you tried to get it.

Q. I have not examined these last tables you have produced, but have you any place figured out what the Niagara increment would be, assuming you could get it, making this 6 per cent. correction for the readings?

A. I did not make the 6 per cent. correction because I think the determination of the increment has got to be separate from that thing. I have made an estimate; I have an estimated value of the Niagara increment.

Q. I say, assuming that you could get the Niagara increment in the same way that you get the St. Clair, the Detroit and the St. Lawrence increment, correcting the gage readings by the 6 per cent. to which you have referred, have you figured out what the Niagara increment would be?

A. No, because I consider that this method of obtaining the increment at Niagara is absolutely unreliable, and therefore I did not spend any time on it.

Q. You did not spend any time on it?

A. (No response.)

Mr. Adcock: Have you made any comparison of the elevations of the lakes for a period or periods before January 17, 1900, and for a period or periods subsequently thereto? If you have, will you state what comparisons you have made and the results that you have reached?

A. The Drainage Canal so-called was opened in January, 1900. Table LXV of Exhibit 34 shows the elevation and mean elevations of the lakes for 10 years prior and for 10 years subsequent to the opening of the Chicago Drainage Canal.

In the first column is given the year.

In the second column is given the average elevation of Michigan-Huron for the year, and the mean of the 10 years; the first 10 years being 1890 to 1899 inclusive; the second 10 years being 1900 to 1909 inclusive.

The third column gives the same information for Lake St. Clair. And the fourth column the same information for Lake Erie.

From this it appears that during the decade next prior to

the opening of the Sanitary and Ship Canal, the average elevation of Lakes Michigan-Huron was 580.342, and that during the decade next following the opening of the Drainage Canal, the elevation was 580.665, showing a rise of .323 feet, or approximately 4 inches.

The mean elevation of Lake St. Clair for the decade preceding the opening of the canal was 575.013 and the mean elevation for the decade following the opening of the canal was 575.255, showing an increase of elevation during the second decade of .242 feet, or approximately 2.8 inches.

Mr. Wilkerson: This table is just a table of——

A. Of actual readings.

Q. Without any attempt to take into consideration any element of change of fact?

A. No, just setting forth the fact.

Mr. Austrian: It is putting it in concrete form.

The Witness (continuing): The mean elevation of Lake Erie for the decade preceding the opening of the canal was 572.012, and the mean elevation of the same lake for the decade following the opening of the canal was 572.210 showing the rise of the lake the second decade over that in the first of .198 feet, or about 2.3 inches.

It is further to be stated that a comparison of the decade next preceding the opening of the Drainage Canal with any decade since the opening of the Canal will show the lakes to have been on the average at a higher elevation during the decade since the opening than during that preceding; and that a comparison of single yearly elevations will show that in no case since the opening of the Drainage Canal has the average annual elevation of the lakes been so low as it was during a single year preceding the opening of the canal.

Mr. Adcock: What increments do you derive for the various rivers? Take the St. Lawrence, Niagara, Detroit and St. Clair Rivers, based upon the facts already in evidence?

A. Considering all the evidence in this case and the fact that, as heretofore stated, the increments derived by direct mathematical computation have been in every case lower than the true increments which would exist, for reasons heretofore stated, the values of the several increments for normal open season conditions appear to be, for the St. Lawrence, about 30,500 cubic feet per second, for the Niagara not less than 34,000 cubic feet per second, for the Detroit about 32,000 cubic feet per second; for the St. Clair about 29,000 cubic feet per second.

Q. When you say "appear to be," do you mean there that is the conclusion which you have reached from the investigations you have made and the facts which you have set forth in your evidence heretofore?

A. Yes, I mean by that that I do not consider that any information that we have is sufficiently accurate or positive to enable any one to say what they are. It is my belief that they cannot be less than the figures which I am giving.

Mr. Wilkerson: Is it your opinion that they are more?

A. I think that the chances are very good that they are more.

Q. I want your opinion. What is your best judgment?

A. Well, I am very well satisfied that they are more rather than less.

Q. I want a statement as to whether you think they are more; if so I want to know how much more; your professional judgment on that.

Mr. Austrian: Whether that is your best professional judgment.

Mr. Wilkerson: If that is your judgment I would like to have you say so.

Mr. Adcock: You mean——

Mr. Wilkerson: Let him answer the question.

Mr. Adcock: You mean from the records?

Mr. Austrian: From the facts that appear in evidence and the deductions made.

Mr. Wilkerson: He is now testifying to a conclusion as an expert. I do not want him to leave the conclusion unfinished. I want him to give his best opinion as an engineer what the correct figure is, so that I may know what I am to go on as a basis for cross-examination.

Mr. Adcock: You mean from the data and material that he has at hand?

Mr. Wilkerson: Yes.

Mr. Adcock: Or what his opinion may be from general conditions.

Mr. Wilkerson: No, I mean his opinion, in the way in which he has reached his opinion, whatever it may be. He has reached an opinion. Now I want to know what it is.

A. I do not think that the increments are any less than the figures which I have given here, and I do not think that they would be more than 10 per cent. greater.

Mr. Adcock: Have you made any calculations from the increments that you have above stated as to the possible effect

upon the lakes of a diversion of 10,000 cubic feet per second? If so state what the results of your computations are?

A. For a diversion of 10,000 cubic feet per second, Lake Ontario would be lowered about 0.327 feet, or slightly less than 4 inches. Lake Erie would be lowered about 0.294 feet or a little more than 3½ inches. Lake St. Clair would be lowered 0.312 feet, or a little less than 4 inches. Lake Michigan-Huron would be lowered 0.345 feet or a little more than 4 inches, about 4⅛ inches.

Mr. Wilkerson: In view of the fact that this testimony is likely to be used in the consolidated case, it would be very convenient if you would give us the figures for 10,000 or 14,000 and 16,000. Of course it is a mere matter of computation, but it would help if we could have the table with those figures.

Q. You haven't them prepared for 14 or 16?

A. No.

Mr. Adcock: As I understand it, the answer to the question that I just asked you is based upon the increments which you have derived there?

A. Yes.

Q. Is that correct?

A. It is.

Q. Would the effect be the same, that is be in the same ratio, for a diversion of over 10,000 second feet up to, say, 14,000, or for any amount under 10,000 feet?

A. Yes, for a diversion of 14,000 feet, the effect would be 1.4 times that which I have given; and for a diversion of, say, 7,000 feet, it would be .7.

Q. Have you considered the question of compensating for any possible lowering of the lake levels?

A. Yes, I have.

Q. Will you state what conclusions you have reached with reference to that subject?

Mr. Wilkerson: I object to the word "possible." I think now it appears that there will be a lowering.

Mr. Austrian: You mean possible lowering by diversion?

Mr. Adcock: By diversion.

The Witness: Or otherwise; they compensate for any lowering.

Mr. Austrian: Yes.

The Witness: The backing up of the upper Detroit River by the Livingstone Channel works and the raising of Lake Ontario by the Gut Dam in the St. Lawrence illustrate the

ease with which it is possible to compensate for diversions from Lake Michigan.

For example, referring to Williams Exhibit 10, it would be entirely feasible to close the Stony Island Channel, and thereby reduce the discharge of the lower Detroit River by about 11,000 cubic feet per second, which would raise Lake St. Clair in the neighborhood of two inches.

The capacity of the Trenton Channel, which was found to be about 36,000 cubic feet per second, could be easily reduced to an extent equal to the reduction of the Stony Island Channel, or even more, by a judicious filling in of material, and thus the compensation of Lake St. Clair obtained for the diversion at Chicago.

The cost of this filling, based upon the prices paid for moving the material in the vicinity of the mouth of the Detroit River, would be about $250,000. The approximate discharges of the several channels at the mouth of the St. Clair River, as measured by the Lake Survey, and given in Williams Exhibit 23, are as follows:

Chenal Ecarte, 11,600 cubic feet per second.

Blind Channel, 400 cubic feet per second.

Bassett Channel, 12,000 cubic feet per second.

South Channel (the one connected with the canal), 59,000 cubic feet per second.

Middle Channel, 33,000 cubic feet per second.

North Channel, 78,000 cubic feet per second.

This makes a total of 194,000, which represents a rather low stage of the river.

From these discharges it appears that either the North or the Middle Channel might easily be restricted to the extent of 15,000 cubic feet per second without detrimental effect, and this would compensate for the lowering of Lake Michigan-Huron by the contemplated Chicago diversion.

The cost of this compensation would be about $500,000, which makes a total of about $750,000 to compensate for the lowering of Lakes-Michigan-Huron, the St. Clair, and the St. Mary's, St. Clair and upper Detroit Rivers.

The construction of the Gut Dam in the St. Lawrence has already compensated for the abstraction of water from Lake Ontario; and the International Waterways Commission are submitting a report upon works to regulate the level of Lake Erie, which, if constructed, would provide for a compensation for the diversion from Lake Erie and the lower Detroit River.

Mr. Adcock: I think that is all. I submit the witness for cross-examination.

Whereupon an adjournment was taken to Friday, July 18th, at 10 o'clock a. m.

Friday, July 18th, 10 a. m.

GARDNER S. WILLIAMS resumed the stand and testified further as follows:

Cross-Examination by Mr. Wilkerson.

Q. How much time have you spent on this case, Mr. Williams?

A. I could not say.

Q. Well, approximately?

A. When was the case begun?

Q. Maybe we can get at it another way: What is the rate of compensation at which you are employed in the case?

A. I am employed at $100 a day when in court; when in conference away from home, $75 per day; $50 per day for office work at home.

In addition to that, there is the services of my office. If you want to get at the time, I can work it out.

Q. I would like to know within reasonably accurate limits how much time you have expended in these different kinds of work.

Mr. Adcock: You mean on this case?

A. I began work in the case very shortly after matters got down to business; I don't know how long after the bill was filed, but I recall it in this way that I had a letter from the Lake Survey Office asking me for my terms; or rather from Major Keller, asking me for my terms in connection with the case. And after thinking it over, as I remember, I did not feel that I wanted to take that side of the case. And the same day I got a letter from the Sanitary District asking me if I would assist them; and I went over to Chicago immediately and began work on the case then. My recollection is that was in November or December but I can't say what year. It was the year that the suit started. I think the bills were filed along in August or some such time as that and I began then.

Since that time, I have devoted a considerable amount of my time, from time to time, as things got warm in the case and they got ready to do something, I would go to work and put in

perhaps the major part of my time for a month, with my office. And then things would be postponed, and I would drop it. Afterwards it livened up again and I would go at it some more.

Mr. Wilkerson: I would like to know if you have your memoranda from which you can give us the information as to the amount of time you have actually put in?

A. I haven't it here in New York; it is in my office. I did not imagine that would be asked for or I might have brought my time sheets for the past five or six years.

Q. It is a matter you can easily determine?

A. Yes.

Q. It involves, as you stated on your direct examination, the expenditure of perhaps half your time for four years, as I understood your statement to Mr. Adcock?

A. I don't think I put it quite as strongly as that, though I might have.

Q. That is my recollection of what you said to Mr. Adcock, that you spent about half your time for four years in the study of this case?

A. I do not believe——

Mr. Austrian: No question of time was asked him.

Mr. Wilkerson: Let him finish the statement.

The Witness: I don't remember the statement at all, but that would indicate more time than I think I individually put on the case.

Q. Your office has put in a good deal of time?

A. My office has put in a good deal of time.

Q. How much time has it put in?

A. I can't say that, because there have been times for three months at a time when we have had active work on this case continuously.

Q. How many men have you had assisting you?

A. I have had anywhere from two to six or eight; not for as long periods as that. I have frequently had two men working on it continuously. I have had two men working continuously; I don't say frequently because that did not cover periods of more than a month or six weeks now and then.

Q. Maybe we can get some idea of the amount in this way: Do you remember how much has been paid you up to the present time, for the combined services of yourself and your office?

A. I think it is somewhere in the neighborhood of $10,000 or $12,000.

Q. That does not cover the services rendered to date?

A. Does not cover the services rendered at the last hearing nor for a considerable time before that. I was paid up to some time——

Q. That would come to about what time, the first of this year?

Mr. Adcock: I think about the middle of March.

A. I think I can tell that; I think that bill either came to the first of March——

Mr. Wilkerson: I will take your statement of the time spent up to the 1st of March.

Mr. Adcock: I think practically that was the time. It might have been later than that or earlier. It was about that time though.

The Witness: That bill apparently was until the 1st of March.

Mr. Wilkerson: To the 1st of March?

A. I think so. I won't say positively.

Q. For what you and your office have done since the 1st of March, the bill has not yet been rendered?

A. The bill has not yet been rendered. I have not figured it up, as a matter of fact.

Q. That would include all the time you spent in the immediate preparation for your own testimony, and in giving it?

A. Yes.

Q. And the services of the employes of your office?

A. Yes.

Q. In working with you?

A. Traveling expenses also.

Q. Compiling the data you have given here?

A. Yes.

Q. And of course your traveling expenses?

A. Yes.

Q. You haven't any idea how much they would amount to, have you? I do not ask you to bind yourself, in a law suit against the District?

A. I think that the services since the 1st of March have amounted to somewhere between $6,000 and $7,000, is my guess, without figuring it up.

Q. That would make your bill for work up to date in the neighborhood of $18,000 or $20,000?

A. I think that is somewhere near right.

Q. If that figure is not approximately accurate, I wish you would refer to your records when you get back.

A. It is approximately accurate.

Q. Refer to your records when you get back to Ann Arbor, and give us the correct figure later on.

Now you have, as a result of this work which you have been doing, you have arrived at or have accomplished certain net results in this case from your standpoint, as I understand it. Let us see whether I am correct or not: As to the effect of the diversion of 10,000 cubic feet of water at Chicago upon the lake levels as measured in the St. Lawrence River, the figure of the International Waterways Commission was 4¼ inches, wasn't it?

A. I do not remember.

Q. I wish you would refer to that to be sure. That is upon the level of Lake Ontario.

A. You refer to the level of Lake Ontario, in the St. Lawrence River, I understand.

Q. Yes, and for convenience I refer to page 76 of the report of the International Waterways Commission for the year 1910, Table XXXVII.

A. That is the figure given in that report.

Q. The figure which was given by Dean Shenehon, witness for the Government in this case, for the effect of the diversion of 10,000 cubic feet per second at Chicago was 4⅛ inches, was it not?

A. I do not remember. I can refer to it.

Mr. Austrian: That is for Lake Ontario?

Mr. Wilkerson: Yes.

The Witness: I assume that is correct. You asked about the St. Clair, about Michigan-Huron?

A. No, St. Lawrence. Mr. Shenehon's figure, as I recall it, was given at Ogdensburg?

A. According to Complainant's Exhibit 2, the scale indicates for a diversion of 10,000 cubic feet, something over 4 inches. I should say between 4⅛ and 4¼ inches for the Ogdensburg gage, as I read the exhibit.

Q. Your own figure for the effect of that diversion, as I recall your testimony, is that it is slightly less than four inches?

A. Yes, sir, I think that was my statement; yes, just under four inches.

Q. It is what you call four minus. That is to say it is slightly less than four inches, and that is your opinion as to the effect of the diversion of 10,000 cubic feet per second upon

the level of Lake Ontario as determined from the observations in the St. Lawrence River, is it?

A. That is my opinion and my best judgment as to the maximum effect of the diversion of 10,000 cubic feet at Chicago upon the levels of Lake Ontario, based upon all the information which I have been able to secure up to date bearing upon the discharge of the St. Lawrence River and its increment.

Q. Well, now, what is your best judgment as an engineer as to the effect of that diversion?

A. That it will not be more than 4 inches.

Q. And that it will be at least within 10 per cent. of that figure, as I understood you yesterday?

A. I don't think I want to put it as strong as that. I would be surprised if it should be more than 10 per cent. less than that figure. But I conceive that it might be.

Q. Your best judgment as an engineer then is that you would be surprised if there was a difference of more than 10 per cent.; you think there would not be more than a variation of 10 per cent. from that figure?

A. I would say my judgment at the present time is: That effect will be between $3\frac{1}{2}$ and 4 inches.

Q. That is your best opinion as an engineer?

A. That is my best opinion at the present moment.

Q. As to the effect of the diversion of 10,000 cubic feet per second at Chicago upon the level of Lakes Michigan-Huron, the figure of the International Waterways Commission is $6\frac{1}{2}$ inches, is it not?

A. Yes.

Q. The testimony of Dean Shenehon for the Government was that five inches plus was the lowest figure which could be accepted as expressing the effect of that diversion upon the levels of Lakes Michigan and Huron?

A. In his opinion.

Q. What is that?

A. In his opinion.

Q. He gave that as his opinion?

A. Yes.

Q. That five inches was the lowest figure which would express it. Your statement of the effect of the diversion upon the levels of Lakes Michigan-Huron is that in your opinion the effect of the diversion is $4\frac{1}{8}$ inches plus. Am I right in that?

A. Approximately.

Q. Well, I want to get—if it is not 4⅛, if there is any other fraction, what is it?

A. Well, that is the closest, I guess the closest that you could get; slightly over 4⅛.

Q. Between 4⅛ and 4¼ inches?

A. Yes, very close to 4⅛.

Q. That is your best professional opinion as an engineer with reference to the effect of the diversion of 10,000 cubic feet per second at Chicago upon the levels of Lake Michigan-Huron?

A. That it will not be greater than about 4⅛.

Q. The same as you said about the other figure, you would be surprised if it should be determined that it was more than 10 per cent., less than that?

A. At the present time, I would put the limits to that at about three and three-quarters.

Q. That is, it could not be less than 3¾?

A. I think it could, but I don't believe it would be.

Q. Your best opinion is it would not be?

A. My opinion at the present time, in the light of such information as I have is that it is not less than 3¾.

Q. What I want is your best judgment.

A. That is the best I can give you.

Q. Your best judgment as an engineer as to the effect of that diversion?

A. All right.

Q. And the figures which you state, 4⅛ to 4¼, with the possibility of a diminution down to 3¾ is your best opinion?

A. Yes.

Q. As to the effect of the diversion of 10,000 cubic feet of water at Chicago upon the level of Lake Erie, I understand the figures of the International Waterways Commission to be 5½ inches?

A. That is as stated in the report.

Q. The statement of Dean Shenehon, the witness for the Government, was that the effect of the diversion of the 10,000 cubic feet upon the level of Lake Erie was 5½ inches?

A. That appears to correspond with the scale on Exhibits 3 and 4.

Mr. Adcock: Complainant's exhibits?

A. Complainant's Exhibits 3 and 4.

Mr. Wilkerson: Your best opinion as an engineer as to the effect of the diversion at Chicago upon the level of Lake Erie is, as I understand you, 3½ inches?

A. Yes. I put 3¼ inches as the maximum limit.

Q. What do you put as the minimum limit?

A. Well, the increment of Lake Erie is so doubtful as to what it is, that is the conditions make its determination so uncertain, that I never have really given very serious thought as to what the upper limit of increment and minimum limit of diversion might be.

Q. What is your best opinion as an engineer as to the minimum figure that could be assigned as representing the effect of that diversion upon Lake Erie?

A. Well, I think I would say at the present moment that it would not be less than two inches.

Q. It would not be less than two inches; and that 3¼ is your best judgment, while it might be as low as two?

A. Th ee and one-half is my judgment of the upper limit?

Mr. Austrian: That is the maximum?

A. The maximum.

Mr. Wilkerson: That is to say, it is your opinion as an engineer that the effect of the diversion of 10,000 cubic feet at Chicago would be less upon the level of Lake Erie than it would be upon the level of either Lake Ontario or the level of Lakes Michigan-Huron?

A. That is my opinion.

Q. And it is your opinion that the conclusion of the International Waterways Commission in assigning to the effect upon Lake Erie a higher figure than upon Lake Ontario is an erroneous conclusion?

A. I believe so.

Q. When did you first confer with Mr. Stearns about this case?

A. Some time early this year.

Q. Approximately?

Mr. Adcock: You conferred with him about the early part of February.

Mr. Wilkerson: How many days in the aggregate have you spent in conference with Mr. Stearns?

A. Prior to his appearance, that is prior to the last hearing, I spent the time from Ann Arbor to Buffalo on the Wolverine, and during the hearing, when I was on the witness stand, and during the days that you gentleman were in Washington, we were all working together on certain phases of this question; and such other time—such other conferences as have been had with Mr. Stearns, limited to a trip down the Sanitary Canal along in May or June, in which there was a

large party of us. Mr. Stearns was along, and in the evening we had a conference of about an hour with various experts, on this case.

There has been no private conference at which Mr. Stearns and I were the only ones present, so far as I can remember, except that first one on the Wolverine, when I presented to him an outline of my testimony and asked him to examine it and see whether he could be of assistance to us in this case.

Q. When you said Washington, you meant New York?

A. No, you and Mr. Adcock went down to Washington and left us there in New York, and we had a three days' recess.

Q. You mean the time when Mr. Adcock and I went to Washington?

A. Yes. When we were in New York, Mr. Stearns was there, and we spent that time in working up data in this case.

Q. How many days all together would you say it amounted to?

A. If you count that in, it might amount to four or five days.

Q. When did you first confer with Mr. Freeman about the case?

A. I conferred with Mr. Freeman at Niagara Falls the day after I conferred with Mr. Stearns on the Wolverine. I got off at Buffalo and went up to Niagara Falls that night to meet Mr. Freeman, and met him the next morning and had a conference of about 20 minutes with him on the subject, and then later in the afternoon had another conference of about, something less than an hour. The next time I saw him was when he appeared here in New York.

Q. Prior to the time when you conferred with Mr. Stearns and Mr. Freeman, are you aware of any engineer who has ever studied this question, who has stated the conclusion that the effect of the diversion of this water would be greater upon Lake Ontario than it would be upon the level of Lake Erie?

A. I don't recall anybody.

Q. And up to that time was it not the unanimous opinion of engineers who had studied this question that the effect of the diversion of this 10,000 cubic feet would be greater upon Lake Erie than it would be upon Lake Ontario?

A. I don't know of any engineers who had studied this question up to that time, outside of those connected with the United States Lake Survey and the International Waterways Commission; and I assume that their opinions are represented by their published reports.

Q. Who are the engineers, as you now recall them, who were connected with the Lake Survey Office, who studied this question?

A. Mr. E. E. Haskell, Mr. Shenehon, Mr. Russell, Mr. Ray. I think those are all you would really put in that class, outside of the Engineer Officer.

Q. Mr. Sabin?

A. I beg your pardon, I should have included Mr. Sabin. That was an oversight; I would say Mr. Sabin also. He should have been put early in the list because he was one of the first ones.

Q. How about Mr. Wilson?

A. I was going to put him with the International Waterways Commission. His study of this thing did not take place until after he went with the International Waterways Commission, so far as I am aware. He worked on the discharge of the St. Mary's River, but I am not aware that he gave any special attention to the general problem until he went with the International Waterways Commission.

Q. Didn't Mr. Wilson investigate slope conditions in the Niagara River in 1903?

A. I think he did, but as I say, it is my impression he did not give any particular study to the general problem.

You can bring in a list of men; I can identify probably 20 who have been connected with this work in one way or another, and have performed certain parts of it, but when you ask who made a study of it, I think the list I gave practically completes it, outside of the Engineer Officers themselves and who I am very much in doubt——

Q. How about Mr. Blanchard?

A. I was not aware that Mr. Blanchard had made any study of the proposition as a whole. Mr. Blanchard was engaged on the St. Clair gagings and also the Detroit River, and then left the service shortly after.

Q. Who are the engineers, who by reason of their connection with the International Waterways Commission have given study to this question?

A. Well, Mr. E. E. Haskell has principally. I don't know to what extent General Ernst has given it study. He may or may not have devoted particular attention to it. And Mr. Wilson, the Secretary of the Commission, has given it a great deal of attention.

Q. Any Canadian engineers, with whom you are familiar?

A. I think that Mr. Stewart has.

Q. Any one else, any other Canadian engineer that you know at all?

A. I do not think that Mr. Coste, who was formerly the engineer member, is likely to have given very much attention to this phase of the question.

Q. Did any one connected with the Deep Waterways Commission ever make any study of this question?

A. I can't be certain whether the Deep Waterways Commission considered the effect of the diversion at Chicago. Their problem was the question of a deep waterway from the lakes to tide water, and they considered various problems connected with that, and incidentally, probably, the Chicago diversion. But at the time that they were working, there was not sufficient definite information to enable a very comprehensive study of the problem to be made.

I think it is probable they did make an investigation along the line of this effect, but I don't recall what it was.

Q. Without regard to whether the effect of the diversion was concerning 10,000 cubic feet per second, they did make a study of the question of the relation between lake levels and the volume of discharge in these respective rivers, did they not?

A. They did in regard to the Niagara, for the reason that they were very suspicious of the supposed outflow of the Niagara River, they having had their attention drawn to the conditions which have been pointed out in this case, of the inconsistency of the supposed river discharge with the discharges apparent in the other rivers, and the later gagings of the upper rivers having reduced the apparent discharge of those rivers slightly, helping to bring the results more nearly into harmony. And the earlier Niagara gagings were undertaken by the Board of Engineers on Deep Waterways in an attempt to ascertain what the discharge of the Niagara actually was, in order to determine the effect of the proposed regulating works upon the level of Lake Erie. And of course incidentally with that, they considered the effect of those works upon Lake Ontario.

As I said before, I do not know to what extent the diversion of Chicago entered into that problem. Of course it was a study of the same thing, in its essentials, but at that time, if my memory serves me correctly, they did not have the St. Lawrence gagings.

Q. I understand that the net result of your work is the expression of the opinion by you as an engineer that the fig-

ures which have been deduced by these various engineers who have been mentioned, as representing the effect of the diversion of water, are incorrect?

A. I think they are in error.

Q. And so far as the Niagara River is concerned, or rather so far as the effect upon the level of Lake Erie is concerned, they have been in error to an extent of between 60 and 100 per cent. of the figure which you state as the correct figure.

Mr. Austrian: No, you do not mean that.

Mr. Wilkerson: Yes.

Mr. Austrian: No, it is the difference between 2 1/5 and $5\frac{1}{8}$.

Mr. Wilkerson: He made his figure $3\frac{1}{2}$. Their figures were $5\frac{1}{8}$. The difference between $5\frac{1}{8}$ and $3\frac{1}{2}$ is $2\frac{3}{8}$. What per cent. of $3\frac{1}{2}$ is $2\frac{3}{8}$—what per cent. of $5\frac{1}{8}$?

The Witness: I have answered the question.

Mr. Wilkerson: The witness gets my point.

The Witness: According to my best judgment the effect of the diversion as reported by the International Waterways Commission is in error approximately 100 per cent.—or no, I should say 50 per cent. when speaking of them.

Q. When speaking of their figures?

A. When speaking of their figures, it is 50 per cent., and 100 per cent. of mine.

Q. You get a figure about half of theirs?

A. I get a figure about half of theirs.

Mr. Austrian: Three and one-half is not a half of $5\frac{1}{8}$.

Mr. Wilkerson: He said 2 to $3\frac{1}{2}$.

Mr. Austrian: He said not less than two nor more than——

Mr. Wilkerson: I was assuming the average of the two limits. I wanted to get his conclusion.

Mr. Austrian: I beg your pardon for interrupting. I didn't understand.

Mr. Wilkerson: Stated in as simple a way as possible, so that we will understand what the net result of his computation is.

Q. Now, as another one of the net results of your work in this case, you have suggested, if I understand it, that there has been a lowering of the level of Lakes Michigan and Huron by the dredging which the Government itself has done in the St. Clair and Detroit Rivers?

A. Not only suggested it, but I have affirmed it and I reaffirm it.

Q. So that we may have it here in the record, what is your opinion as an engineer as to the extent to which the levels of Lakes Michigan and Huron have been lowered by the dredging which has been done in the St. Clair and Detroit Rivers?

A. At least .6 of a foot.

Q. By that you mean .6 of a foot is the lowest figure?

A. Yes, I mean it has not been lowered less than that in my judgment.

Q. What is your maximum figure?

A. Oh, about twice that, 1.2, say.

Q. Is it your opinion that that is merely a possibility, or is that your best opinion as an engineer that it has resulted in a lowering of 1.2 feet?

A. I think that is the upper limit.

Q. That is to say it is a possibility?

A. It is a possibility.

Q. But not probable?

A. I would say that it is not probable the effect has been more than a foot. I hardly think it is possible it has been more than 1.2.

Q. So between .6 of a foot and a foot——

A. Below a foot is where I really think that the result is to be found.

Q. Now, I understand as another one of the results of the work which you have done in this case, you have presented a statement and a table which show, in your opinion that since the diversion of water through the Chicago Drainage Canal, the level of Lakes Michigan and Huron has actually increased?

A. I think that is correct. They have actually increased, placing my faith upon the records of the United States Lake Survey.

Q. Is it your opinion as an engineer that the diversion of water by the Sanitary District at Chicago has had the effect of raising the levels of the lakes?

A. Certainly not.

Q. What then, so far as the question of effect upon the lake levels is concerned, is the weight which in your opinion is to be given to that table?

A. Merely a statement of fact?

Q. Merely a statement of fact? That is Table LXV?

A. I guess so. That is the table is a statement of fact.

Q. In other words, what inference, as an engineer, is it

your intention that the court at the hearing of this case shall draw from your table number LXV, so far as it throws light upon the question of fact which is involved in this case?

A. That the lakes are actually higher now than they were before the diversion. That is all.

Q. In your opinion, does it throw any light at all upon the question of fact as to the effect of diversion?

A. None whatever.

Q. None whatever?

A. (No response.)

Mr. Austrian: May I ask you this question, to clear up the record a bit: You do not question the accuracy of that Table LXV, as I understand it; that is that the lake levels are higher now than they were in 1900?

Mr. Wilkerson: I am the counsel. I would not care to question the accuracy of the table. I am merely trying to find out from the witness what aid he expects the court in this case to get from his table number LXV, from which he has reached a conclusion of fact.

Mr. Austrian: Just for the sake of putting it in readable form.

Mr. Wilkerson: In other words you put it in there because counsel told you to?

A. They didn't tell me to, but they asked me to; and it being a plain statement of fact, with no opinion connected with it, I saw no reason why it should not be put in.

Q. As a matter of fact, you say, when asked today about it, that it did not have the slightest thing to do with the facts in this case?

A. I don't think I would put it as strong as that.

Mr. Austrian: I object to that.

Q. You took it from records compiled by the Government itself?

A. I did, and I believe the table to be a correct statement of fact. That is all there is to it.

Mr. Wilkerson: Isn't it perfectly obvious to you as an engineer that the only effect which could result from the use of that table would be somebody might use it in an attempt to confuse the court as to the testimony in this case.

Mr. Austrian: That is objected to. I ask the witness not to answer the question.

Mr. Wilkerson: The witness, under the instruction of counsel, declined to answer the question.

Q. I understand as a result of the work which you have

done in this case, another one of the net results is that you have indicated a scheme of compensation which might be employed for the purpose of bringing the level of the lakes back to the point where they would be if water was not diverted at Chicago?

A. Yes.

Q. And that scheme in general, as I understand it from your testimony yesterday, and I have not had the benefit of reading your testimony, so I am speaking from memory, involved the filling in of certain channels?

A. Portions of certain channels.

Q. Portions of certain channels. Those channels which it is proposed to fill in are navigable channels, are they not?

A. Yes, and the proposed filling would not interfere with navigation.

Q. That is to say in your opinion it would not?

A. That is the fact——

Q. It would be the placing of material in a navigable channel of the United States?

A. Yes.

Q. That is what it amounts to, isn't it?

A. Yes.

Mr. Adcock: You started a sentence that you did not finish.

A. I said it would not be an interference with navigation.

Mr. Wilkerson: But of course whether it would interfere with navigation or not is something for the Government itself to determine.

Mr. Austrian: I object to that. That may be a conclusion of law from your viewpoint, but you are asking this witness to testify to facts and not law.

Mr. Wilkerson: I am satisfied if I understand from the witness that the scheme of compensation involves the filling in of channels which are navigable.

The Witness: Yes, it involves the adoption of the same plan which has been adopted by the Government in the lower Detroit River.

Q. In addition to the contradiction of the figures of the Lake Survey and the International Waterways Commission, the statement as to the effect upon the level of Lakes Michigan and Huron by the dredging which the Government itself has done in the St. Clair and Detroit Rivers, the scheme of compensation which has been suggested and the statement as to the actual condition of the Lake levels since the diversion of the water at Chicago, do you now recall any other

general propositions that you have put forward here as representing your conclusions in this case? I am not now speaking of comments upon methods of computation but I am speaking of what might be called ultimate net results of your work.

Mr. Adcock: Do you understand the question?

A. It is a little hard to say just where you would draw the line.

Mr. Wilkerson: He understands it.

The Witness: It is a little hard to say just where you draw the line between what are, as you say, the ultimate facts and the subordinate facts; the ultimate conclusions and preliminary conclusions.

Q. Indicate a subordinate conclusion, which in your opinion is not covered by one of those general propositions which I have stated?

A. The proposition that would seem to me might be included in that category, although quite possibly would be relegated to a minor position would be that the gagings at Niagara cannot be depended upon for the establishment of the increment that comes in the——

Q. That comes in the criticism of the other conclusions as to the effect of the diversion. And the basis for your conclusion of fact is that you have an idea as to the value of the Niagara measurements?

A. Yes.

Q. Do you think of anything else now except that?

A. So far as I recall the testimony, and dividing it into the categories as you suggest, I think you have covered it; although I would like to add this: That the showing that the International Waterways Commission and the Lake Survey are in error in the effect of diversion is not what I have in mind in thinking of this proposition. I would have been very glad to have agreed with them in their conclusions.

Q. But you did not?

A. But I did not, and my conclusion is that the effects are so and so; not that the other fellow's are wrong.

Q. Of course if your conclusions are right they are necessarily wrong?

A. Yes, but I do not have to conclude that.

Mr. Austrian: That is a polite way of giving the lie direct.

Mr. Wilkerson: I think the counsel on the other side has stated the effect of it accurately.

Q. In speaking of your experience as an engineer, I think

you mentioned that you had been connected with another phase of litigation, to which the Sanitary District was a party?

A. I was.

Q. That was the case of the State of Missouri versus the State of Illinois and the Sanitary District of Chicago?

A. It was.

Q. A suit, an original bill as I recall it, brought in the Supreme Court of the United States?

A. It was.

Q. About 1903, or rather your testimony was in 1903?

A. It was about that time, yes, I think 1903. I think that is correct.

Q. What was the question that was involved in that case?

A. It was an application for an injunction on the part of the State of Missouri for the benefit of the City of St. Louis to restrain the City of Chicago from discharging its sewage into the Illinois River, on the theory that it would pollute and injure the water supply of the City of St. Louis.

Mr. Austrian: And thereby promote disease and be a public nuisance and so forth.

Mr. Wilkerson: Q. You were retained in that case as an expert witness for the State of Missouri?

A. I was.

Q. How much time did you spend on that case?

A. About a month.

Q. Including the time of preparation and testimony, at the same rate of compensation that you have in this case?

Mr. Austrian: I object to that question because the law is that it is perfectly permissible to inquire as to the compensation of an expert witness in the case at bar; not in other cases; and especially where the compensation is not paid by the same person to the controversy.

Mr. Wilkerson: Let him answer, subject to objection.

A. I think my charge was on the same basis as this.

Q. That it amounted to about $3,000 all together?

A. Something of that sort.

Q. That is approximately the figure?

A. Yes.

Q. Your testimony in that case was before the Supreme Court, was it not?

A. It was.

Mr. Austrian: You do not mean before the Supreme Court. You mean before a commissioner?

Mr. Wilkerson: It was taken before a commissioner and was in the record when the case was argued before the Supreme Court, so that it was before the Supreme Court.

Mr. Austrian: Yes.

Mr. Wilkerson: Q. You are familiar with the printed record in that case, are you?

A. I have seen the volumes, but I think I have not seen the testimony.

Q. I direct your attention to pages 2467, 2468 and 2469, from which I shall read into the record and ask you—

Mr. Austrian: Whose testimony?

Mr. Wilkerson: Testimony of Gardner Stewart Williams, taken at the Southern Hotel, St. Louis, Missouri, at 2 p. m., on Tuesday, the 26th day of May, 1903. Present: The commissioner, and the same counsel representing the respective parties. That was John Hamline and Mr. Todd, as I recall it, for the State of Illinois and the Sanitary District, and General Crow and Judge Johns.

Mr. Austrian: Is that testimony in abstract form or verbatim?

Mr. Wilkerson: It purports to be question and answer.

The Witness: I think it is verbatim.

Mr. Wilkerson: Q. I ask you to look at the portions I have marked on pages 2467, 2468 and 2469. I ask you to state whether or not, according to your best recollection, that is the testimony, or part of the testimony which you gave on that hearing?

Mr. Austrian: That is the questions that were put and the answers given.

Mr. Wilkerson: The questions that were put and the answers given as there set down according to his best recollection.

A. I think that is my testimony.

Q. I now invite your attention to the following, page 2467: "Q. Mr. Williams, I will ask you as an expert on water supplies, for cities and towns, passing your opinion upon the subject broadly, in your judgment is there any present or impending or future danger to the people of the State of Missouri using the waters of the Mississippi below the mouth of the Illinois for drinking purposes, which danger would be due to the discharge of the mixed sewage of the Sanitary District of Chicago and the waters of the Drainage Canal into the

Illinois River other than the infection with typhoid fever germs of the waters of the Mississippi River."

Mr. Austrian: We make special objection to the question put, and the answer thereto, and all subsequent questions because thus far it does not appear that that testimony would tend to prove any issue involved in the present controversy. And it is stipulated that all this testimony, question and answer, may go in subject to objection.

Mr. Wilkerson: We have a stipulation that was made at the outset of the testimony, that any objection which did not involve the form of the question, or something which could be corrected at the hearing, might be pressed at the hearing of the case with the same effect as if there made; and it was understood that that applies not only to questions on the direct examination, but, of course, to the questions on cross-examination.

Mr. Austrian: Very well.

Mr. Wilkerson: I would think, however, that if the objection is that it is not proper cross-examination, and the objection were one which could be obviated at the taking of the testimony before the commissioner, it would be proper to indicate the reason why it is not proper cross-examination, so that if it can be corrected, we may have the opportunity of doing so.

Mr. Austrian: You would have to call him as your own witness, but we do not make that point.

Mr. Wilkerson: Your objection is the particular objection.

Mr. Austrian: Yes, you could cure that by merely calling the witness as your own.

Mr. Wilkerson: Yes.

Mr. Austrian: We do not make that objection.

Mr. Wilkerson: Your objection is that the testimony itself is inherently incompetent.

Mr. Austrian: Yes; does not tend to prove any issue, so far as I know anything about it. It might develop later that it does tend to prove the issue.

Mr. Wilkerson: (Q.) (Continued.) "A. In the history of water-borne diseases in America, while typhoid fever plays an important part, it comes far short of playing the entire part. Not only Asiatic cholera, but a large number of our common American diseases are undoubtedly transmitted through the water. Among those germs which have been found to have a considerable length of existence in the water

are the germs of diphtheria, tetanus and anthrax, as well as a considerable number of germs which are derived from the diseases of the lower animals.

The germ of anthrax, for instance, is capable of producing very serious disease in both man and beast, and there have already occurred in the City of St. Louis cases of anthrax, one of which has been traced apparently to the water supply, and the germ of anthrax is reported to have been already found in the waters of the Illinois River. Anthrax is primarily a disease of the lower animals, and in France, where it has been specially prevalent, in some provinces it has been no uncommon thing for 10 per cent. of the sheep to be destroyed by it in a single year.

A peculiarity of anthrax is the remarkable length of life of the spores or seeds—whichever you may choose to call them—in water, they having been known to exist in it not only for months, but for years, and are practically indestructible. Should anthrax be present among cattle which are daily slaughtered in the Chicago Stock Yards, and from them be transmitted by the discharges from the nostrils, mouths or bowels of these cattle, into the sewers of Chicago, there would be no question that the germs of anthrax might easily find a lodging in the people of Missouri with extremely fatal results. The germs of anthrax may not only be taken into the human system and produce disease by passing into the intestinal tract, but it is also susceptible of producing disease as the result of inoculation, so that a person bathing in water in which there were present germs of anthrax, if he had on his body any abrasions of the skin would be particularly liable to receive an infection from anthrax which might very probably end fatally.

It is not an uncommon thing for anthrax to be communicated to those who are handling the skin of animals and who may become scarred or bruised in the course of their occupation.

The germs of anthrax being practically indestructable under ordinary conditions, is frequently conveyed in hides and skins, and in the refuse from leather manufacturing establishments might easily get into the sewage of the City of Chicago as well as by way of the Stock Yards.

The people of the State of Missouri resident in the counties bordering upon the Mississippi River are largely engaged in stock raising, and in times of drouth, the Mississippi River is practically the only source of water for the stock so raised,

and it has come to my knowledge that in such times, this water is parted for many miles from the shores of the Mississippi River to be used by both stock and the human inhabitants of the country adjacent. Should the sewage of Chicago become infected with the germs of antharx, and should those germs be transmitted as they undoubtedly would be into the waters of the Mississippi if the Chicago Drainage Canal continues to discharge the sewage of Chicago into the Des Plaines and Illinois Rivers, at such times there would be great danger of the occurrence of an epidemic of anthrax, not only among the human inhabitants of the State of Missouri, but also among the lower animals using the water.

Anthrax is recognized as one of the worst of water-borne diseases with which we have to contend, for the reason that when once it becomes established in a community it may attack both man and beast, and its eradication can only be accomplished by the absolute destruction of the bodies of animals so infected.

It is able to live for long periods of time in the earth, and may thereby be communicated long after the death of the primarily infected animal to other animals grazing over the surface.

I may add further that the disease commonly known as glanders is also transmitted through water, and that it is not an uncommon disease among the stock of this country at the present time, and the discharge of the sewage of Chicago, which is at any time liable to be contaminated by glanders, into the Illinois River, is another source of danger to the inhabitants of Missouri.

In fact, as we look into the future and see the probable growth of Chicago, both in industries and in population, and the added probability of infection of its sewage due to the more general spread of infectious diseases, it seems to me that the danger impending over the citizens of Missouri as the result of the discharge of the sewage of Chicago through the Drainage Canal into the waters of the Illinois River is a most fearful menace to the life and welfare, not only of the citizens of Missouri but of the citizens of other cities below the mouth of the Illinois River leaving entirely out of consideration the question of typhoid fever."

You recall that as having been given in the course of your testimony?

A. I do.

Mr. Austrian: Just here I think it is only fair for the coun-

sel for the Government to state the purpose of reading that part of the testimony into the record.

Mr. Wilkerson: The question is put to the witness because we conceive, first, that it is proper cross-examination of the witness upon the matters with reference to which he has testified in this case. That the opinion which he has there expressed is a proper subject of comment to be made upon his testimony as a whole, in the case at bar.

In addition to that we conceive that, passing the question of proper cross-examination which I understand is not specifically pressed as an objection to the question, the testimony is unquestionably competent because it deals with an issue as to which a large amount of evidence has already been presented by the defendants in this hearing.

Mr. Austrian: Will you stipulate that so far as this testimony is concerned, that question and answer which you have read, the witness shall be considered your witness, we not objecting to the form of the question.

Mr. Wilkerson: No, I am not making him my witness.

Mr. Austrian: On that point.

Mr. Wilkerson: I do not know any rule of evidence by which testimony, if it is proper cross-examination, then I am entitled to use it for any purpose in the case.

Mr. Austrian: If you conceive it is proper cross-examination. Inasmuch as it does not tend to show his interest, and inasmuch as it does not tend to elucidate any question put to him on direct examination, I don't think it is proper cross-examination.

Mr. Wilkerson: I think it is. I do not care to argue it.

Mr. Austrian: To get the record right, you have no objection to my raising the objection at this time that it is not proper cross-examination.

Mr. Wilkerson: Nor at the hearing; you may raise it at the hearing.

Mr. Austrian: I did waive it.

Mr. Wilkerson: Because if it is not proper cross-examination, I am frank with you when I say I do not see that there is any way we can cure the matter at this hearing. If it is not cross-examination you may make the objection at the hearing.

Mr. Austrian: Very well.

Mr. Adcock: You suggested that specific objection should be made.

Mr. Wilkerson: I stipulate you may reserve the right to make at the hearing the objection this is not proper cross-ex-

amination. And I suppose you will give me the stipulation if it is proper as our own testimony and it should be held it is improper cross-examination, I may use it as my own testimony, if I see fit to do it at the hearing, without recalling the witness.

Mr. Austrian: Yes.

Mr. Wilkerson: You gave that as your best professional opinion upon that subject, did you, Mr. Williams?

A. I did.

Q. And it is your opinion, I assume?

A. With some slight modification due to the advances of science in the past ten years.

Q. But it is substantially correct?

A. Substantially.

Q. And I direct your attention to page 2472, to the following: "Q. Mr. Williams, assuming that an epidemic of Asiatic cholera should occur at the City of Chicago under existing conditions of sewerage in said city, and existing conditions in an open drainage canal, the Des Plaines, the Illinois and the Mississippi River, and the existing conditions with reference to the intake tower of the St. Louis Water Works, and the storage and distribution of the water from the chain of rocks to the consumers in the City of St. Louis, I will ask you as an expert on water supplies for cities and towns is it possible or probable that the germs of that disease might find their way into the intake tower of the St. Louis Water Works at the chain of rocks and thence to the consumer?

A. In the event of an epidemic of Asiatic cholera in Chicago under the conditions now existing in the waters between Chicago and the chain of rocks, through which the sewage of Chicago now flows, there is not only a possibility but a probability, and almost a certainty, that the germs of the disease would be communicated or transmitted to the water supply of the City of St. Louis and the consumers thereof.

Q. Now, Mr. Williams, what effect if any would the conveyance of Asiatic cholera germs have under those circumstances upon the people of the City of St. Louis?

A. It would undoubtedly lead to an outbreak of Asiatic cholera in the City of St. Louis."

You recall that, do you?

A. I do. Wait a minute; I do not specifically recall that answer, but I have no reason to doubt it as it is what I would have said under the circumstances exactly.

Q. You gave it as your professional opinion?

A. Being in the record, it is undoubtedly what I said. It is my opinion.

Q. You adhere to it?

A. I adhere to it, yes.

Q. I direct your attention to another portion of the same record beginning on page 2475 of the volume to which I have above referred.

"Q. Now, Mr. Williams, looking forward into the future and considering not this generation alone, but those that are to follow, and considering the relation of the filth and infection of the Chicago sewage to the water of the Mississippi River as it flows along the Missouri shore, I will ask you to state your views as an expert on public health matters, regarding the above mentioned conditions, considered as a broad practical proposition.

A. . With regard to the effect on future generations of the discharge of Chicago sewage into the Illinois River and thence into the Mississippi River, and its effect upon the water of the Mississippi River, I would say that there is no question in my mind but that the problem before future generations is one of far more difficult solution than that which we face in the present.

A careful study of the relations existing between the flow of the rivers which contribute to the water flowing past the chain of rocks, and the prevalence of water borne diseases in the City of St. Louis among those of her citizens who are users of the public water supply has led me to the conclusion that at the present time the remarkable immunity from serious typhoid infection which the citizens of St. Louis have thus far experienced, although they have been using water which is unquestionably at the time of entering the intake considerably polluted, is due very largely to the character and amount of water contributed by the Missouri River.

I long ago learned to appreciate the importance from a sanitary standpoint of Missouri River mud. As the Missouri River enters the Mississippi River, the amount of silt in suspension in this water amounts oftentimes to over 1,200 parts in a million. A large portion of this silt is of such a nature as to be quite readily deposited as the water approaches a state of approximate quiescence, and such a vast quantity of depositing mineral matter mixed thoroughly throughout the water of the settling basins of the St. Louis Water Works cannot fail and analyses show that it has not failed to remove a very considerable percentage of the bacteria which are daily

brought into these settling basins in the water as it comes from the Mississippi River.

Laying aside the question for the moment of the possible increase of infectious matter in the water supplied through the intake at the chain of rocks due to the increased growth of the City of Chicago and the other populations upon the drainage area of the rivers which contribute to the St. Louis water supply, it is to be borne in mind as time goes on the history of the Mississippi River will become the history of every other stream upon whose borders the hand of man has rested, and that while the total quantity of water which that stream will deliver from year to year will remain about the same as now, the quantity of water which will be delivered in times of drouth will be decidedly less than heretofore, and that larger and larger portions of the discharge will be concentrated in a few floods. The result of this upon the waters mingling to form the supply of St. Louis will be that in the future, the Missouri River will show a greater diminution in the percentage which it represents of the flow past the city than will the waters derived from those other two streams upon which the hand of man has rested for so long a time, that comparatively small changes are to be anticipated in the future in the quantity of their low water run-offs. It will therefore follow that the amount of silt furnished by the Missouri River will be less and less sufficient to remove from the mixed water the number of disease germs which even now exist there, leaving alone the possibility, or probability and the certainty that the number of those germs will vastly increase as time goes on.

It therefore seems quite clear to me that any added pollution of the waters of the Illinois or the Mississippi River will have from year to year a greater and greater effect upon the healthfulness and quality of the water which will be delivered under circumstances similar to those now existing in the treatment of the water delivered to the citizens of St. Louis by their water works system, and when we consider that in the City of Chicago there is now a population representing about one-third of the total urban population upon the watersheds tributary to the Mississippi River at St. Louis, and probably representing more than one-sixth of all the population resident upon those water sheds, and that now no city in this portion of the United States, or indeed in any portion of it, has shown such remarkable and rapid growth both in population and in industries as Chicago, there can be no ques-

tion that in the future the menace to the health of St. Louis arising from the discharge into the Illinois River of the sewage of the Chicago Sanitary District will be a much more tremendous and impending danger to the citizens of Missouri living along the Mississippi River below the mouth of the Illinois, than exists at the present time, grave though the present condition be."

Do you recall that question and answer?

A. I do in general, yes.

Q. And you state the same with reference to it as you did with reference to the other questions and answers, as to your having given it as your professional opinion?

A. I gave it.

Q. And as to your present opinion as to its correctness?

A. I gave it as my professional opinion at that time, and I think it is substantially correct at the present time.

Q. Do you know what happened in that case?

A. I do.

Q. The bill was dismissed, wasn't it?

A. Without prejudice to either side.

Mr. Austrian: With leave to re-file, if the menace to the people of Missouri became imminent.

The Witness: Yes.

Mr. Wilkerson: I asked that question, so that it might not be necessary to put in the opinion. We can refer to it if we want to.

Mr. Austrian: Certainly.

Mr. Wilkerson: Q. The result of the litigation was, was it not, that St. Louis adopted a different method of treating its water supply?

A. Yes, instead of trying to preserve it in its natural purity, they adopted methods of purification.

Q. Of course the method which St. Louis adopted is one which could be used in Chicago or any other large city.

A. No, it is a materially different proposition. The conditions at St. Louis are peculiar and require a treatment suited to those conditions. It is like treating ague or treating smallpox; you treat them differently.

Q. That is it would make a difference in the kind of works?

A. In the method of procedure.

Q. In the method of procedure?

A. In the method of procedure.

Q. In this work which you did in the Missouri-Illinois case, did you come in contact with current meters?

A. I do not recall. I think there were some gaugings involved in the discussion.

Q. In estimating the time it would take germs to go from one place to another, were there any measurements made by current meters?

A. No, that was done by floats. Floats were put in at Robey street, and were actually traced down the river; the floats being followed by parties in boats, and the time taken from point to point.

Q. My understanding and recollection was that there was a specific mention in that litigation of the use of current meters, and that use was made of them on your side of the case for the purpose of measuring the velocity of the water and determining the rapidity with which germs get from one place to another?

A. They might have been used. I do not recollect that detail at present; but the fact was time of transmission was established by the time it took the floats to pass down the river, by actual observation.

I think that records of the discharge of the Illinois River and Des Plaines were introduced to show that these floats were sent down, not at flood time but at low water. And it is quite possible that use was made of those results to indicate the probability of the time being greater or less..

Q. Your recollection is not definite?

A. My recollection is not definite, but I think it is quite probable, in fact, I am sure there was some information furnished as to the flow of the streams at different seasons of the year, whether it was obtained from current meters or from discharges over the dam at La Grange and Kampsville; there were three, in fact, or four.

Q. What I was getting at is whether current meter observations were used in that case, and were taken and accepted as results which were entitled to credit by scientific men.

A. Oh, they would be within reasonable limits, certainly.

Q. Now in your direct examination you made mention of a service which you performed as engineer for the Detroit Water Board. Is that the correct name of that?

A. Board of Water Commissioners of the City of Detroit.

Q. And in that connection you made measurements in the Detroit River?

A. We made some current meter measurements in the Detroit River, yes.

Q. Just what was the purpose of the measurements?

A. The purpose of those measurements was to determine the locations of the main currents in the American channel, for the purpose of locating the intake for the water works. It was not primarily for the purpose of measuring discharge.

Q. How extensive were those measurements?

A. There was a considerable amount of work of measuring velocities and direction of current done. I don't recall now just how much time it covered; and there was a gauging of the American channel made through the ice during the winter of 1896 and 1897 or else 1897 and 1898, I guess.

Q. Were the measurements limited to the American channel?

A. The current meter work was limited to the American channel.

Q. What instruments did you use?

A. Used a Ritchie-Haskell Direction Current Meter.

Q. How did you rate the meter?

A. We did not rate it, because the question of the magnitude of the current was unimportant; it was simply the relative—wait a minute, I say we did not rate it. I would not be sure about that, either. For the bulk of our investigations we did not care about an accurate rating, and we took the maker's rating.

My recollection is not altogether clear, but I have in mind that the meter was rated in the canal at the water works, on second thought, by attachment to a boat and dragging along the side of the canal.

Q. This was not a piece of work which was of the same kind and magnitude as the work which has been under discussion in this case, was it?

A. No, there was no attempt made to make an accurate examination of the quantity of water passing. It was purely an approximate determination so far as the quantity was concerned. We cared very little about that. It was rather to find out how the currents were distributed.

Q. Was this rating a still water rating?

A. It was still water; any rating we made was still water.

Q. Was the ratio of velocities fairly stable at the different stations?

A. No, not at all.

Q. I think you said you did not aim at a very high degree of precision in this work?

A. Oh, no, we were not trying to measure the quantity of water?

Q. Did you make a report?

A. No, there was no formal report made. The results were reduced and an approximate measurement of the flow in the American channel was derived, which surprised us at the time on account of the smallness of it. We had supposed more water was going down that channel than appeared to be.

Q. You say this was to locate the intake?

A. It was with a view of locating the intake, yes.

Q. How did you finally locate it?

A. We finally gave up the current meter as being too difficult to operate and too deceptive in its indications for our purposes, and resorted to the thermophone, which is an instrument which records the temperature at the points where the instrument may be, and transmits it by means of a telephone, or something in the nature of a telephonic recorder, to the ear, and with that we made cross sections of the river from the water works well up into Lake St. Clair, and in the spring, of course, and summer—in the summer particularly, the colder water was coming from Lake Huron, and the warmer water from the shore, and the variations of temperature enabled us to locate quite fairly the position of the Lake Huron current.

In the winter, of course, the conditions were reversed, the shore water being the colder and the lake water the warmer; and we did some work late in the fall and early in the winter, but the bulk of the work was done in the summer.

Q. There was not anything in this work that involved what might be called a careful or critical study of current meter work, was there?

A. I think we got pretty thoroughly familiar with the idiosyncrasies of the instrument, and the difficulties which are encountered in current meter measurements.

Q. Was that the first time you had come in contact with those idiosyncrasies and difficulties?

A. That was the first work I did with the current meter.

Q. That was not your last current meter work, was it?

A. Hardly.

Q. You mentioned some work which you did in the Cornell Hydraulic Laboratory, did you not?

A. I think so.

Q. Do they have a canal there for the purpose of making this kind of obversations?

A. The Hydraulic Laboratory consists in part of a canal about 400 feet long, controlled by sluice gates at its upstream end, and having in normal condition two bulkheads across it, one about 75 feet from the inlet end, and the other at the lower end, where there is also provision for letting the water out through sluice gates.

The lower portion of the canal is equipped with a track, and a trolley is now operated on it electrically, which affords an opportunity for rating current meters or other instruments of that sort in still water, by simply filling the canal with water and closing the inlet gates.

Q. How large is the volume of flow in that canal?

A. When you are rating it is not anything, that is when it is closed. We have handled—

Q. I should have said at the different velocities at which the water flows. I want to get some idea of the size of that canal.

A. That canal is 16 feet wide and 10 feet deep at its upper end, and has a slope of 1 in 500; 1 foot in 500; so that the lower end is about 11 feet 4 inches deep, as I remember it. And water may be run through it at any depth from just enough to wet the soles of your feet to 10 feet.

Q. Take a depth of 10 feet, and with the weir conditions which you had there, how much water went through this canal?

A. We have handled very close to 500 cubic feet per second through that canal.

Q. Well, how does that compare with the quantity flowing through the Sanitary District Canal, through the diversion of 10,000 cubic feet? That would be about 2½ per cent. of it?

A. Oh, more than that.

Q. Five per cent.?

A. It bears about the same ratio to the water flowing through the Sanitary Canal that the water flowing through the Sanitary Canal bears to the water flowing out of the Great Lakes.

Mr. Austrian: That is, if the Sanitary Canal was running 10,000 cubic feet per second?

A. If the Sanitary Canal was running 10,000 cubic feet per second.

Mr. Wilkerson: Q. Which is 5 per cent. of 10,000 cubic feet per second; and of the water flowing out of the Great Lakes, say through the Niagara River, what per cent. would it be?

A. A quarter of one per cent., about ¼ of 1 per cent.

Q. You made some measurements in the St. Marys River?

A. We did.

Q. When and where were those made?

A. Those were made between Point Brush and Pointe Aux Pins, about six miles above the locks.

Q. For what purpose were those made?

A. They were made for the Michigan-Lake Superior Power Company, who were at that time interested in showing the effect of a diversion of water through their power canal upon the flow of the river, or upon something in the vicinity. I do not know that I am entirely clear as to just what their purpose was.

Q. You had some specific work in which you were engaged, some project?

A. These measurements were undertaken before the permit for the opening of the power canal was granted, if I remember correctly; and it was thought at that time, I think, that there might be some controversy in regard to the amount of water that could be diverted. At any rate the Lake Superior Power Company wished to either make, or pretend to make some measurements of the St. Mary's River at that point.

Q. I do not just understand that phrase "make or pretend to make." Was there any significance in the use of the word "pretend"?

A. Yes, there was.

Q. What was there?

A. The history of the Lake Superior Corporation shows that it was generally pretending to do things, and whether that it really meant to make those measurements or not, I am very much in doubt.

Q. You were not pretending, were you?

A. I was not.

Q. Was there anything that took place before you made the measurements that gave you the impression that you were just merely going there to go through the form of doing something, without regard to the accuracy of the results?

A. No, not at all; the precautions that were taken to insure accuracy were certainly such as I think would meet the criticisms of the representatives of the Lake Survey, at that time at least.

Q. What method did you use?

A. Well, meters were rated in the ordinary way in still

water by dragging from a truck in the laboratory in Cornell University. A provision was made for re-rating them in the Bay at Pointe Aux Pins, Wheeler Cove, for re-rating in Wheeler Cove, in a similar location to that used by the Government Engineers in the rating of their meters for the St. Marys River discharge; and various propositions were considered for handling the boat.

One contemplated stretching a cable across the channel, which I never could quite agree to, as I felt very sure that it would be, not an imaginary but a real obstruction to navigation, no matter how expertly the ends of it might be handled, when steamboats came down there with the frequency that they did. The work was finally done by shifting anchors.

Q. You are speaking of the gaging?

A. I am speaking now of the method by which what might be termed the co-efficient work was carried out, or rather the determination of index velocities—perhaps that is a more proper term—the establishment of the co-efficient. And we encountered very serious obstacles, which also must have been encountered in the work of the Lake Survey, although until recently there has been little mention of it, namely the effect of passing boats upon the distortion and disturbance of the vertical curve. We found that the vertical curve would be very greatly disturbed by passing boats, even though they were a considerable distance away.

I regret that I do not have with me the results of those observations, as there is some rather instructive information in there as to the effect of that sort of disturbance.

Q. You say the difficulty was on account of passing boats?

A. Yes, of steamers coming down. The water was about 50 feet deep there, and of course boats were then loading to about 18 or 19 feet.

Q. What year was that?

A. No, they were not loading as deeply as that because the lower channels in the St. Marys were not large enough. I hardly think they were loading more than 16 feet at that time.

Q. What year was that?

A. That was in 1900, I believe, or 1889. I will not be certain.

Q. After your Detroit measurements?

A. Yes, that was either 1899 or 1900.

Q. This difficulty arising from passing boats was a difficulty which was encountered in some of the earlier observations on the St. Clair?

A. I do not recall there was much said about it in the earlier reports. Latterly in some more recent ones, the matter has been treated.

Q. It was not encountered, was it, in the measurements that have been made by the Lake Survey in the Niagara and St. Marys?

A. No, it was not in the Niagara. It might have been in the St. Lawrence, though I do not know.

Q. I wish you would give us the particulars of the cross section which you selected for this work; the depth and other physical characteristics.

A. In my office I have the information that would enable me to give specifically what you are asking; but I can give you in general an idea what that cross section was.

Q. I will ask you to give it in general?

A. On the American Shore, there was for a distance of perhaps 500 feet more or less a shallow that I think at no point was more than 8 feet deep; running from that to practically nothing, and beyond that the channel deepened quite abruptly, and to a depth of in the neighborhood of 50 feet. Referring, for the purpose of refreshing my memory, to William's Exhibit 2 entitled "Chart 3 of the St. Marys River," the channel was about 1300 feet wide at this point, and the depth indicated on this chart is 53 feet, which coincides with my recollection of about the depth we had in the deepest portion of the section.

The total width of the river appears on the chart to be about 2400 feet.

Q. What was the speed of the current?

A. I don't recollect it at the present moment.

Q. Pretty slow water, was it?

A. No, that was moderately swift. I should say it was somewhere around three feet a second.

Q. Mean velocity?

A. I will not be sure. Of course the flow through the shallow portion was negative part of the time; it was flowing backward, so that that was treated separately.

Q. Was it exposed to wave action?

A. Not to any—at least at no time when I was there did the waves interfere. In the case of the wind in a certain direction, you might have, I would think, very considerable waves there, as there was quite a long—

Q. How much time were you there?

A. Oh, I was there probably a week.

Q. Out of how long?

A. Oh, they were working on the thing from about the beginning of August until cold weather, intermittently. I do not know that they were working continuously. A considerable part of the time was spent in preparation, getting things ready to work with, establishing ranges and all that sort of thing; and I rather think that they were not actually engaged in gaging operations, not more than a month, and in that time they probably were not on the river half the time.

Q. You were there that week during the month when they were making the observations?

A. No, I was there during the time they were making the preparations, laid out the scheme, and then did not go up again. I got weekly reports of the progress, and lack of it.

Q. Well, when there was an upstream wind, wasn't there difficulty in keeping the boat on the section line?

A. So far as the location of the boat on the section is concerned, that was controlled by ranges, and the boat was kept there within a comparatively narrow margin. As to the amount of difficulty they had doing it, I can't say, but the boat was manned with a number of oarsmen, in addition to the anchors.

It is quite possible that if the wind were blowing up-stream, it would have been more difficult to hold the boat in place.

Q. Did you use anchors?

A. We used two anchors ordinarily.

Q. To hold it when the wind was down-stream, as well as up-stream?

A. We used it wherever the anchors were needed.

Q. Now the result of your experience on the Detroit River has been such as to give you the opinion that these current meters ought not to be used when you wanted to get very accurate results out of them?

A. It gave me the opinion that we could do considerable better by the use of floats, wherever floats could be used. And we did make some runs on the St. Marys with floats, but on account of the extreme depth of the water, it was impossible to get a float that would measure the lower portion of the stream, so that the current meter was all you could use?

Q. So you reached the conclusion that that was the best method of making these measurements?

A. For that situation, yes.

Q. Where were your water gages located?

A. There was a gage located at Brush Point and across

the river at Foot's Dock, and the gage below at the head of the canal, maintained by the Government. The records were assumed to be available to us, so that we didn't attempt to put anything down below.

Q. You took the Government measurement as accurate?

A. We took the Government gage record at the Soo for anything we wanted below the section.

Q. And accepted that?

A. Oh, yes.

Mr. Adcock: Q. That was the gage record showing the elevation of the lake at the time?

A. The elevation of the water.

Mr. Wilkerson: Q. You superintended the work of combining these observations so as to reach a result, did you?

A. We never got far enough to reach a result.

Q. Did you attempt to reach a result?

A. No, because we never got clear across the river. All we did was the reduction of the individual verticals, the plotting of the observations.

Q. Why didn't you go across the river?

A. Well, it was partly on account of the difficulty of getting through the steamers, and partly for lack of satisfactory equipment for handling the apparatus. The difficulty of handling the thing from a row boat was very considerable, on account of the slowness with which you were able to move from place to place, and it was proposed to make use of a launch the following season. And the work was finally suspended with that understanding, so that we considered the work that we had done up to that time as of a preliminary nature, and indicating to us the difficulties we were likely to encounter.

Q. So the result of your work was that between August and November, you really failed to get any result as to the measurement of the river, was it?

A. That is correct; we did not make a complete gaging of the river except—let me see, the floats I think gave us information extending across the channel but I cannot be certain, because I have not looked at those results for several years. I do not remember now just to what extent they did go.

Q. You made no attempt to derive an increment?

A. Oh, no.

Q. Nor did you derive any equation of discharge?

A. No.

Mr. Adcock: Q. Was there any question of increment involved there?

A. No, there was no question of increment involved at the time. The question of lowering was not being considered at all. It was a question as to whether they had the right to take a certain amount of water.

Mr. Wilkerson: Q. You were measuring the quantity of water?

A. We started out to measure the quantity of water simply.

Q. Have you in mind a similar experience which the Deep Waterways Commission had on the St. Lawrence River?

A. I never was familiar with the work which the Deep Waterways Commission did on the St. Lawrence. It was my impression that they made no gagings there; whether they attempted it or not, I don't really know.

Q. I assume from what you have said, Mr. Williams, that your final conclusion was that the section which had been selected for this work was an impracticable one, wasn't it?

A. No, I should not say that. The passage of boats interfered very materially, and for satisfactory work there it would have been necessary to make the observations at times when boats were not passing. It would have had to have been done late in the fall, or times of fog.

Q. Or select a cross section some place else?

A. Well, you could not get a cross section in the St. Marys River, or it would be very difficult to get a cross section in the St. Marys River, where you would not have more or less trouble with passing boats.

Q. You could have obtained a better section than you had, couldn't you?

A. I rather doubt it. Of course at first sight, one would prefer the International Bridge.

Q. That is to say if you had a swifter velocity, a more compact section, you would expect better results?

A. Provided it was not too swift, provided there was not too much disturbance there.

Q. Von Schon measured a section above the bridge, didn't he?

A. Not that I know of.

Q. You are not familiar with that piece of work?

A. No.

Q. You said, not that you know of. Did you ever hear about it?

A. I have no recollection of it. This work, of course, was done by direction of Mr. Von Schon, as Chief Engineer of the Lake Superior Power Company.

Q. You do not know what he might have done on another occasion?

A. I do not know what he might have done on another occasion, but Mr. Von Schon had previously been in the service of the United States Engineer's Office, and whether he made any gagings at that time or not I could not say.

Q. You would not be surprised if it were a fact that he did pick out another section, and actually make final, definite measurements?

A. I would not be surprised if Mr. Von Schon made some further measurements. I think he did not, however, after this date.

Q. Do you know whether Mr. Von Schon ever made any hydraulic measurements for the United States Government?

A. I am not aware that he did. I am not particularly familiar with his experience while he was connected with the United States Engineer Office. I think Mr. Shenehon, who was a colleague of his in the office at the time, could give abundant information on that head.

Q. What I was trying to find out is: I understand it to be a fact, and I thought we could get it here, that after the time you embarked on this work, which was only partially completed, there was in fact another section which was measured, and the work was prosecuted through to a finality.

A. I think not. To the best of my knowledge and belief that is not the case.

Q. That is you mean by Von Schon?

A. Yes. The United States Engineers were measuring the discharge prior to this and afterwards, which measurements of course are of record. But I am speaking of the work done by the Lake Superior Power Company.

Q. You have spoken of the Detroit and the St. Marys Rivers. Are there any other rivers of that size, on which you have done any work?

A. Current meter work you mean?

Q. Yes.

A. Which I have personally done?

Q. With which you have had anything to do in the way of supervising the work, or being responsible for the results of the work?

A. No, I think not.

Q. So that as preparation for, and as a basis for your criticism of these engineers who have done successful work, you have never done any successful work yourself, have you, Mr. Williams?

Mr. Austrian: I object to the form of the question.

Mr. Wilkerson: That is a fair question.

Mr. Austrian: No, "These engineers who have done successful work" that is a matter of opinion.

Mr. Wilkerson: If the witness has done any work in which he has ever successfully measured a stream such as the ones under consideration in this case, I would like to have him state it.

Mr. Austrian: There is no objection to that question.

Mr. Wilkerson: All right.

The Witness: What is the question?

Q. (Question read.)

A. I have not, and I doubt if anybody else has.

Q. Your doubt is based upon your experience, isn't it?

Mr. Austrian: His doubt is based upon his conclusions.

A. No, my doubt is based upon the records of such observations by other people, as well as my own experience.

Whereupon a recess was taken to 3 o'clock p. m.

After Recess 3 p. m.

GARDNER S. WILLIAMS resumed the stand for further cross-examination by Mr. Wilkerson and testified as follows:

Last question and answer read as follows:

"Q. Your doubt is based upon your experience, isn't it? A. No, my doubt is based upon the records of such observations by other people, as well as my own experience."

Mr. Adcock: Q. Does that complete your answer to the question put?

A. Yes. I am entirely willing to strike out the last part of that answer if you want to. I think it is not responsive.

Mr. Wilkerson: Q. I think you said in your direct examination, Mr. Williams, that you had measured some small streams?

A. Yes.

Q. Which ones?

A. I measured the Huron River, that is to say I supervised the measurement of it. I never actively—

Q. What river is that?

A. Huron River, Michigan; the Tittabawassee River, and a number of other small streams that I have measured.

Q. Let's have some of them.

A. Fall Creek, or better say Six Mile Creek, Ithaca, New York, Taughannock Creek, near Ithaca. I can't think of the name that the stream went by in the northern part of the state, near Traverse City, a small stream; the Black River in Michigan; the Chippawa, Cedar, Pine. That is all I think of at the present moment.

Q. Please take them up in order and state as nearly as you can the volume of flow of each one of them, and mean flow.

A. The Huron River mean flow is about 400 cubic feet per second. The Six Mile Creek mean flow, I have forgotten what the mean flow of that stream is at the present moment. The minimum of the creek about 25 cubic feet per second, the maximum running it up to about 10,000 for a maximum.

Q. What were the measurements?

A. 10,000 on one measurement, and others in between. I think I measured it down as low as about 15 cubic feet a second, as I remember now.

Q. What river was that?

A. That is Six Mile Creek, near Ithaca, New York. I am not speaking of current meter measurement wholly. I do not want to be misunderstood as to that.

Q. I understood you did not use a current meter on an of these?

A. Oh, yes, I have used the current meter a good deal.

Q. Let us have the volume first; then we will get the detail of the measurements?

A. I can't recall those figures, Mr. Wilkerson. I will be very glad to supply them to the Commissioner and introduce them in the testimony.

I will say now I do not think there is a stream involved, whose average flow is over 2,000 feet a second. My memory is 1500 for the largest, but I will give you the actual average discharges.

Q. That is all right, unless you think you are able now to state them approximately.

A. I am not because I do not try to remember those things. I have a memorandum, but the only one I remember is Huron.

Q. You think no one has more than 2,000?

A. As an average discharge, there is nothing more than 2,000 cubic feet per second.

Q. Do you remember at this time the particulars of the work which was done with reference to the Huron River?

A. Oh, yes, the discharge of the Huron River has been measured various ways, by current meters, by floats, by the measuring of the head over dams, or measuring the water that went through wheels; that is using the water wheel. As a matter of fact it has been gaged all those ways, and finally for a very low flow we went so far as to gage the water that flowed over a dam, in barrels.

Q. In any one of the pieces of work you did on the Huron, did you use the current meter?

A. Oh, yes.

Q. How many times?

A. Several times. I don't remember exactly but we always had one around the office; used it more or less.

Q. What was the thing you were endeavoring to determine, the quantity of water?

A. The quantity of water passing.

Q. On which one of the other rivers that you have named did you use the current meter?

A. We used the current meter on the Black; used the current meter on the Tittabawassee, on the Chippewa. I don't know, we used it every little while as far as that goes, used it frequently.

Q. In your experience then in the measuring of these various streams and rivers, you have made use of the current meter as an instrument by which you thought you could arrive at a conclusion with reference to the volume of water flowing through the river?

A. Yes, and expect to continue to do so.

Q. And made reports with reference to each one of them, in which you gave your conclusions based upon observations taken with the current meter.

A. I frequently make reports in which I make use of current meter measurements as a basis of approximating the flow in the stream, yes. I won't say I have done it in all these cases, but I have in several of them.

Q. In your professional experience, you assume as one of the elements which has entered into the result which you have stated, that the current meter is a proper instrument to be used for that purpose?

A. Certainly.

Q. And that is not only your own experience, but it is that of engineers generally, is it not?

A. It is generally accepted as a proper instrument, and in many cases as the only instrument that can be used; under certain circumstances it is the only one that can be used.

Q. And in the great majority of cases, it is the best way, isn't it?

A. It is not the best way—

Q. The best practical way?

A. No, I would not say that. What I would say is this: That there are a large number of cases, and probably at least 75 per cent. of the cases, where you are called upon to measure the flow of water, where the current meter is the best means that can be applied. Where the channel is of such a nature as to permit of the use of floats, a more accurate measurement can I think be obtained, and oftentimes better results can be obtained by the combination of the two than could be obtained by either one alone.

Q. The use of the floats is subject to very considerable mathematical uncertainties, is it not?

A. Not so much as the use of the current meter. The float passing in a vertical plane down through the stream, you are quite assured that you have the mean velocity of the water from the surface to the bottom of that float represented by the velocity of that float. Now, the current meter to get that same information has to occupy sundry positions in the depth that is covered, so that the float is integrating the velocity through the area over which it travels.

Q. Can you use the float in measuring—

Mr. Austrian: Let him explain fully, in detail.

A. (Last answer read.) And when a number of floats are run down through a stream at various points in the cross section, each one of these floats covers points covered by the current meter in a vertical only it covers it more completely, as far as the length of the float goes. The difficulty with, or the limitation of the float lies in the fact that if the bottom be rough, the float has to be a considerable distance above the bottom to prevent its being stopped by the obstructions; and you also have to take into consideration a possible change in area of your cross section through the course that your float travels over, so that it means that you must have a channel of practically uniform section for a reasonable distance; that is one over which you can time the passage of the float, and without introducing large error in the time element.

The other limitation is that it is not ordinarily practicable to use floats in very deep water, for the reason you can't handle a float that must be weighted sufficiently to stand erect and have buoyancy enough to carry it down a large stream. I think that about 30 feet is about the limit of depth that any one has handled floats in, so far as I know; I mean vertical rod floats.

I have no particular confidence in the so-called double float. That is only a shade better than the surface float to my mind.

Mr. Adcock: Q. What is the double float?

A. The double float consists ordinarily of two balls, one of which drifts on the surface, and the other is connected to it by a chain or wire or string. and floats at some distance below the surface; and it is supposed in that way they would get some sort of a measure of the velocities below the surface.

The objection to that method is that there is no certainty as to where the lower ball is; it may be vertical under the upper one, or lagging behind or moving ahead; the cord may be inclined or curved; and it is practically impossible to tell what the lower one is doing.

Q. How is the float you have mentioned here constructed and used?

A. We ordinarily take a pole of dry wood and load it at the bottom. One way of doing it in the field is to load it with sheet lead, load sheet lead upon the bottom by wrapping it around the bottom until the float will stand erect in the water, with a small amount of the top exposed. Then this float is released in the current in a vertical position and floats with the current over a measured course, the time of travel being taken, and of course that measures the velocity through the range that it travels; and by putting in a series of floats across the river you get the same thing you attempt to get with your current meter by taking a series of verticals.

Mr. Wilkerson: Q. Does the water flow with the same velocity at the surface as it does down near the bottom?

A. No, it does not.

Q. What determines the rapidity with which the float moves down?

A. The average volicity of the water.

Q. Do you have to apply a mathematical correction to determine what the mean velocity is?

A. Not for the portion of the channel that is covered by the float itself. When you come to extend the discharge to the bottom of the stream, then in the lower portion of the stream

you must make a—some sort of a correction. You must either do as you do with the current meter, sketch in the curve at the bottom, just as all these observations have been done, or you must adopt some mathematical method of computing it.

There has been devised a formula for application in that case, which I have tested in reasonably smooth channels and have found to give very accurate results, considerably better than we were able to get with the current meter. But when you come to apply it in a stream with a rough bottom, why it—

Q. Or a deep stream?

A. Or a deep stream, where you can't reach to the bottom, that lower portion of the curve must be investigated in some way.

Q. 30 feet is the limit?

A. I think 30 feet is as deep as any one has operated. And I would not like to be positive that that depth has been handled.

It is perhaps interesting in that connection to note that when the Haskell Current Meter was first put upon the market, its accuracy was established by a comparison with floats; and it was shown that they agreed, that the meter agreed with the floats within a small percentage. That statement was published in the catalog of the Ritchie Company, and in fact I think I saw it not long ago in print.

Q. By what process of reasoning do you reach the conclusion embodied in the statement which you make that the float travels at the mean velocity of the stream?

A. Because the observations which have been made on that head show that to be the case. That subject is investigated quite at length in the Lowell Hydraulic experiments by Mr. James B. Francis, published about 1855 I think. I think you will find it discussed in the first volume, I mean the first edition; and while it is theoretically possible to prove that the float will slide down hill, will slide down the water plane a little faster than the water moves, even that correction is one in fractions of a per cent., and experimental observations indicate that the float is measuring the water through which it passes with a more satisfactory degree of precision than I have been able to get out of any current meter work that I have known of.

Q. Is it not a fact that Mr. Francis has reached the conclusion that the current meter travels at a mean velocity, by a mathematical deduction?

A. He reached the conclusion that the float would theoretically travel faster than the water, by a mathematical deduction.

Q. Then he devised the formula by which it was to be corrected?

A. No, he did not. His formula was based upon his experiments. He measured the quantity of water flowing in channels with floats, and compared it with the measurement of water flowing over a weir, and by using floats of different lengths he was able to determine an expression for the correction to be applied to cover that portion of the stream which the float does not actually traverse, if you choose to make that computation mathematical. If you do as in the current meter measurements simply plot your curve and draw your curve in, you do not need any mathematical computation. Then it becomes a matter of experience to draw that somewhere near where it ought to be.

Q. Do you know how many days Mr. Francis covered in his observations, which were used as the basis for this conclusion which you have just stated?

A. I do not. A portion of his work is published in the Lowell Hydraulic Experiments. Whether it is all there, I am unable to say. But independent of Mr. Francis, I caused a series of investigations to be made at Cornell upon the same subject, and in that we spent—oh, we were working on it parts of two years. We worked almost continuously on it for pretty nearly a month, and from those results we found that our float gagings ordinarily checked the weirs within about 1½ per cent., 1½ to 2. At the same time, the current meters were checking within from 3 to 4, ordinarily.

Q. These observations as to which you have just testified were made in this 16 foot channel which you mentioned this morning, weren't they?

A. Those at Cornell, yes.

Q. And at Lowell they were measured in a canal?

A. They were measured in a canal there, the width of which I do not remember positively. I have in mind that it was somewhere in the neighborhood of 50 feet in width, but I am speaking solely—

Q. Do you know the range of velocities which was covered by the floats in either one of the two sets of measurements about which you have testified? Have you got the figures in mind at the present time?

A. I haven't the figures in mind at the present time. At Cornell, let me see—I do not want to say; I thought I could

tell but I can't. My guess at the present moment would be that we did not go over 5 feet.

Mr. Adcock: That is 5 feet a second?

A. Five feet a second.

Mr. Wilkerson: At Lowell, was it any more than that?

A. I think not.

Q. Was it much less than that?

A. My recollection now of the Lowell experiments is they were around 2 feet. Is that your recollection, Mr. Shenehon?

Mr. Shenehon: That is my recollection.

The Witness: That is as I recall it. That is a matter that can be looked up.

Mr. Wilkerson: You and Mr. Shenehon are agreed?

The Witness: If Mr. Shenehon has looked them up within a few days, I will take his word.

Mr. Shenehon: No, I have not.

Mr. Wilkerson: Let me ask you this question: Is it not a fact that the data which are at hand relating to the measurement of streams by floats are comparatively meager and are in small streams compared with the ones on which the data in this case were taken?

A. Well, floats were used quite extensively on the Mississippi River of, I think all types. In general however the float measurement is not used for the reason that it requires a large party to operate; that is you cannot handle float measurements in a stream of any size without a party of three or four times the men that are necessary for current meter measurement.

Q. So that comparatively speaking, the data available with reference to the use of floats would properly be said to be meager?

A. Well, it depends a little bit on just what you mean by meager. The floats have been compared with the number of gagings made by current meters, I think within the past 20 years have been at least 1 to 10; that is, there have been at least ten meter gagings to one float gaging.

Q. So that it is fair to say that the current meter is the generally accepted instrument to use?

A. Oh, no question about that; it is the instrument ordinarily used for this purpose.

Q. It has been your experience that the results have been correct within 3 or 4 per cent.?

A. No, I would not say that.

Q. I understood you to say that?

A. No; where under exceptional conditions we were check-

ing them against the weir, at Cornell, we were able to get within sometimes as close as 2 per cent. of the weir, but the conditions there were extremely favorable. There was no question as to the character of the section, as to the area. The bottom and sides were smooth, so that it was possible to get the current meted down very close to the bottom, closer than is possible in ordinary streams; and the velocities were screened and smoothed out, so as to give quite regular flow, so that the conditions there it seems to me would be more favorable than ordinary field measurements.

Q. Is that the only place where you had an opportunity to check absolutely the accuracy of current meter measurements, where you had the opportunity of measuring the quantity of water passing over the weir?

A. No, we had a case recently for the Sanitary District, in connection with the test of some pumps at Wilmette, where the water delivered to the pumps was measured by current meters, and the water after passing the pumps was measured over a weir. We had an opportunity to check there.

Mr. Adcock: Did I understand you to say the Ritchie Company, the manufacturer of these current meters that have been used by the United States Lake Survey, in their catalog representing the value of their meter, and so forth, the accuracy of the meter, state that they approach or are designed to approach the accuracy of floats?

A. They show a comparison in there of discharge measurements, by float and meter, and show how closely the meter checks the measurements by floats.

Q. Do I understand that they consider the float as the most accurate measurement?

A. Apparently, as the generally accepted method at that time. Bear in mind that was—

Mr. Wilkerson: This was a statement in a catalog 20 years ago, is that it?

A. No, this was a statement that applied to the time the Ritchie-Haskell Meter was invented. When was that, 1880 or 1890?

Q. At least 20 years ago.

A. As I say, it is 20 years ago.

Q. It was a statement in a catalog 20 years ago?

A. No, I saw that statement, I received that catalog considerably less than 20 years ago. But the point I am getting at is this—

Q. Some old statement, like most catalogs, they continue from year to year?

A. No, let me explain: At the time the Haskell meter came into use, the float was recognized as a standard method.

Q. That was the only method before they invented the meter?

A. That was really the—that was the only method of reasonable accuracy that was available for field measurements on a large scale, up to the time the current meters were introduced, and naturally the comparison was made with them.

Now, my purpose in referring to them was simply to call attention to the fact that at the time the current meter was introduced, the float was recognized as a standard method. Now it has been superseded by the current meter on account of the greater ease with which the observations can be made, not on account of greater accuracy, except in cases where it would be, you might say, practically impossible to measure with a float, on account of the depth or irregularity of currents.

Q. In these Sanitary District measurements which you have testified about as being made at Wilmette, what was the velocity of the water which was being measured?

A. I think the average velocity was about 4 feet a second.

Q. What was the volume?

A. It was around 280 cubic feet a second.

Q. Just one more question about this catalog statement to which Mr. Adcock has made reference: I will ask you whether you remember whether the float which was used as a check against the accuracy of the current meter measurement was a surface float or a sub-surface float?

A. Rod float.

Q. How deep?

A. I don't recall now.

Mr. Adcock: When you speak of the rod float, it is the float that you described a little while ago?

A. As a rod floating vertically in the water.

Mr. Wilkerson: But not reaching close to the bottom?

A. At Cornell University, we used floats with an immersion of 98 per cent. That is to say, we got within 2 per cent. of the bottom of the channel.

Q. You had a smooth bottom?

A. Yes, we had. That is why I say our deductions there established the fact that the float moves with the mean velocity of the water through which it travels, because we covered something over 90 per cent. of the cross-section of the channel with the float; that is taking both the variation from the sides and the bottom.

Q. There are not many cross-sections you can get that way, in measuring actual streams?

A. That is what I say.

Q. That is why we use the current meter instead of the float usually?

A. That is one reason why.

Q. As a matter of fact, Mr. Williams, there is no use in talking about using a float to measure the rivers that we have been discussing in this case, whatever may be said about small canals or small creeks or little rivers? You cannot use a float to get the measurements to refer anything to, in the kind of rivers we are discussing in this case, can you?

A. I think they would have gotten more accurate results if they used floats to cover as much as they could, and leave the current meter to take care of the bottom, where they could not reach it.

Q. But they did not?

A. They did not. You asked whether they could.

Q. As a matter of fact it has never been done successfully?

Mr. Austrian: Where?

Mr. Wilkerson: In large rivers; the size of the rivers connecting the Great Lakes.

A. There has been a good deal of that work done on the Mississippi River. How successful they regard it is more or less a question. It all comes to a question of relative precision.

Q. What is your opinion as an engineer as to the degree of precision with which the flow in the Mississippi was measured by floats?

A. I am not in a position to express an opinion in regard to the rod float work that has been done on the Mississippi River, as I have never studied the details of it. As I said a short time ago, so far as the double float work is concerned, I consider it practically worthless. But that is another proposition. The float measurements usually criticised on the Mississippi River are those double-float measurements.

Q. You know nothing about the rod floats?

A. I have never examined any records of the rod float gagings, and am not ready to speak of it.

Q. Do you know how engineers generally regard it?

A. Those with whom I had discussed the matter, who had experience with both the current meter and the rod float expressed a preference for the rod float wherever they could use it.

Q. Who did express that?

A. I think at this moment of George Y. Wisner.

Q. Anybody else?

A. I think that is the only one I happened to discuss the subject with.

Q. In connection with what river?

A. We were speaking generally, wherever you could use the float. The float was to be preferred to the current meter but there are a good many places where you could not use it at all, and there were other places extremely inconvenient or expensive.

Q. When was that opinion expressed?

A. That was expressed about 1899 or 1900. It was during the work at Cornell when we were experimenting with floats for the Board of Engineers on Deep Waterways.

Q. He had a good deal to do, didn't he, with the measurements made in connection with the compensating works on Lake Erie?

A. He was a member of the Board of Engineers, the Deep Waterways Commission.

Q. They did not use any rod floats there?

A. No, because it was not a suitable place to use them, for one reason.

Q. He used the current meter?

A. Yes.

Q. And he treated the current meter measurement as entitled to scientific credit, didn't he?

A. He always was very critical—

Q. I am speaking about his published reports?

A. All right, then his published reports speak for themselves. If you are asking me what Mr. Wisner thought about it, that is another matter.

Q. We haven't any way of knowing what he thought except through the reports.

Mr. Austrian: He may have expressed himself.

Mr. Wilkerson: We have his expression in the published reports.

Mr. Austrian: That may not have been his entire expression.

Mr. Adcock: Did he ever express himself to you in regard to the matter?

A. I do not know whether there is to be anything gained by going into that. I will say this in answer to Mr. Wilkerson's question, that Mr. Wisner—that the Board of Engineers on Deep Waterways made use of the current meter at Niagara as the most available means of measuring the flow of Niagara,

and they used it—and being the only information, and the best information, they based their conclusions upon it. I know however that Mr. Wisner, up to the time even of his death, was always skeptical of those Niagara measurements. I talked with him about that only a short time before he died.

Mr. Wilkerson: You do not recall any published documents, in which he said he lacked faith in them?

A. I think not. In the report of the commission, of course nothing of that kind would have been in good form, or permitted, perhaps, by the other members of the commission.

Q. He undoubtedly would have given expression to his real professional opinion in any report which he made?

A. I do not think that that thing got to the point of a professional opinion. I say he was suspicious of those records but they were the best that he had and he used them.

Q. In what years were those measurements made?

A. I say I discussed that matter with him a very short time before he died.

Q. In what year?

A. He died in 1905, 1905 or '06 somewhere around there.

Q. You say you made some measurements on the St. Lawrence River?

Mr. Adcock: Were you going to go into that question? You asked him about the measurements for the Sanitary District of Chicago. As you have referred to it, I think it only fair that he explain his connection with that matter and the results of the measurements.

Mr. Wilkerson: I think he covered that.

Mr. Adcock: No.

Mr. Wilkerson: If there is anything further that is proper, I am entirely willing to have him state it.

Mr. Adcock: And the results of his experiments there, in connection with it, because as it stands now it is merely referred to. You may draw deductions and so forth that may or may not be proper.

Mr. Wilkerson: Is there anything about that, Mr. Williams —I think you answered my question.

A. I did, I answered the questions you asked me. I think all you asked me was if I had compared current meters with weirs anywhere else than at Cornell. I mentioned that case; gave the volume.

Q. I asked you about the size, the volume of water that was measured and the velocity, and we had some such discussion here.

A. Yes.

Q. The effect of which was that was hardly a proper kind of stream with which to make an appropriate comparison?

A. (No response.)

Q. Now about the measurements which you made on the St. Lawrence River, when were they made?

A. The measurements on the St. Lawrence were made in, I think, about 1909 or 1910. I will give you the dates if you allow me to go upstairs.

Q. We can have them approximately; I do not care for the exact dates.

A. I will say about 1910. I will not be certain as to the year without looking it up. Time has been passing pretty rapidly since I got into this case.

Q. For what purposes were they made?

A. They were made to determine the flow of the St. Lawrence River, in connection with the proposed power development in the Couteau and Cedar Rapids.

Q. Did you measure the full flow of the river?

A. Yes. Don't misunderstand me; you say "Did I"? I didn't do the measurement myself. I advised in regard to the measurement, and recommended the parties who were engaged to do the work. The results were submitted to me and examined by me and criticised and were made use of in connection with some further work in connection with the power development; but I was not present during the gaging.

Q. Who was selected to make the measurements?

A. Mr. Murray Blanchard.

Q. Who is he?

A. He had charge of the gagings on the St. Clair, during 1902, wasn't it, Mr. Shenehon?

Mr. Shenehon: He was under Sabin.

The Witness: He had charge of them the last year according to Mr. Haskell's testimony. I am quite sure the last year's work that was done under Mr. Haskell, prior to 1908, was done by Blanchard as Chief of the party. And he then came down and had charge of the Detroit measurements. Let me settle that, because I do not want anything wrong in here. I am speaking from recollection of Mr. Haskell's testimony. (Referring to same.)

On page 51 of the continuously paged record, the question is asked: "Who was in charge of the work there?" the reference being to the St. Clair. "A. Mr. L. C. Sabin for the first two seasons, and Mr. Murray Blanchard for the third season. Q. Were they competent men for that work? A. They were."

Mr. Wilkerson: Was he hired on your recommendation?

A. He was.

Q. What method was used in measuring the flow of the river?

A. The ordinary methods of the United States Lake Survey.

Q. Used with your approval?

A. They were.

Q. Were water gages used?

A. Yes.

Q. How were the readings taken?

A. By observers at regular intervals during the observations. They did not use recording gages if I remember rightly.

Q. Were current meters used?

A. Current meters were used.

Q. What kind?

A. Haskell, and a Price.

Q. How were they rated?

A. Rated in still water by dragging in the usual manner, the procedure being similar in every respect to that adopted by the United States Lake Survey, which was then and is now regarded as the best practice in current meter work.

Q. Was there a law of discharge established as the result of those measurements?

A. There was not. The purpose of the measurements was to determine what correction should be applied to the gagings of the Lake Survey to make them applicable to the St. Lawrence in the location where the work was done, that being a considerable distance further down the river; and it was desirable to know how much greater or less the flow of the river at that point was than was indicated by the gagings at Waddington by the United States Lake Survey.

Q. For that purpose, you accepted the report of the Lake Survey at that point as accurate?

A. We accepted it as relatively accurate, yes.

Q. Did you make any report which was based upon the work of the Lake Survey as supplemented by your own work?

A. No, there was no written report made. We appeared in court, or rather appeared at a hearing before the Prime Minister and his Cabinet.

Q. And gave testimony?

A. And gave some testimony in regard to it. That is, we did not as a matter of fact give the testimony; we appeared but the testimony was given by others, and Mr. Noble and myself, who were interested in the matter, were not called upon to participate.

Q. You and Mr. Noble were on the same side of the case, were you?

A. We were.

Q. At that time you both agreed as to the manner in which the observations on the St. Lawrence were to be viewed?

A. That particular question did not come up at all. They were the best information we had as to the discharge of the St. Lawrence.

Q. You did not suggest there any necessity of recomputing the work of the Lake Survey by any methods of weighting the measurements, did you?

A. No, the matter of 10,000 cubic a second more or less was not of any particular consequence in that case.

Q. Well, did you suggest the necessity of rejecting any observations?

A. We did not discuss those observations at all.

Q. You just simply took the work of the Lake Survey as accurate for the purpose for which it was to be used?

A. We did.

Q. That was in a lawsuit—

A. Except to this extent: That we investigated to see what the difference was at our section over what was indicated at theirs.

Q. But in the work of the Lake Survey at that point, the gage elevation was used for the time of measurement and not for 24 hours prior, or a period of several days prior?

A. The question of gage elevation did not enter. We simply took the results as the United States Lake Survey had published them, and accepted them as being sufficient for our purposes. As I say, the matter of 10,000 cubic feet per second was of small consequence there.

Q. That is to say for the purpose of that case, it would not have made any difference whether the flow was determined accurately within 10,000 cubic feet?

A. It would not, no.

Q. Within what degree of accuracy were you interested in the result?

A. Well, we were contemplating on leaving somewhere between 40,000 and 60,000 cubic feet for the uses of navigation, as I remember it; 20,000 was sufficient for all they really would need, and we were going to leave them a large surplus, so that the question whether it was 10,000 feet more or less in that particular case had very little bearing. That is all there is to it. We made these measurements of our own to be sure, or to be able to say that we had measured it, or that the river had

been measured at this locality and that it was so and so, and we compared those measurements with the measurements by the United States Engineers. The gagings on the St. Lawrence referred to were made in 1909.

Q. I referred this morning, Mr. Williams, to some of these engineers who had done work and had reached conclusions on this subject involved in this case, in connection with their position on the International Waterways Commission and the Deep Waterways Commission and the Lake Survey. I direct your attention particularly to Mr. C. B. Stewart. What do you know about his work?

A. Mr. Stewart was in charge of or connected with the gagings on the Niagara for the Board of Engineers on Deep Waterways.

Q. Do you know anything about his hydraulic investigations at Wisconsin University?

A. Mr. Stewart has been engaged on hydraulic investigations at Wisconsin for some years back. I have received bulletins concerning the investigations from time to time.

Q. What is his standing as an engineer?

A. I am hardly qualified to say, as I have not followed his work closely and I do not know that I have ever discussed his work with anybody. I should regard Mr. Stewart as a very capable investigator.

Q. What do you know about the work of Mr. E. E. Haskell?

A. Mr. Haskell is recognized as an authority on current meter work; particularly on river hydraulics; had a long experience with the Government in the United States Lake Survey; and also has been engaged on hydraulic work for the Government in various capacities, on the Mississippi River Commission and with the Coast and Geodetic Survey; and was connected with the measurements of the Gulf Stream a number of years ago. And then he was Principal Assistant Engineer in charge of the Lake Survey; now Dean and Director of the College of Civil Engineering at Cornell, and a member of the International Waterways Commission.

Q. Is he in charge of the Hydraulic Laboratory at Cornell?

A. The Hydraulic Laboratory at Cornell University is attached to the College of Civil Engineering, and as Director, he of course has control of the laboratory. I think Professor E. W. Schoder is recognized as the engineer in charge, being of course under Mr. Haskell, so far as the supervision of the head of the department is concerned?

Q. What chair does he hold there, what is his title?

A. Who, Mr. Haskell?

Q. Yes?

A. I think he is Professor of Hydraulic Engineering. I do not remember what else.

Mr. Shenehon: Experimental hydraulics.

The Witness: I do not recall ever having noticed what the title actually was.

Mr. Wilkerson: He has had a very extensive experience, has he not, in water measurements?

A. He has done a great deal of it.

Q. He has had to do with water measurements on a large scale?

A. Yes, he is one of the leading authorities on the subject. There is nothing that I can say that would be too high commendation of Mr. Haskell's attainments.

Q. And in your opinion as an engineer, any conclusion which he might reach as to a fact concerning water measurements is entitled to great weight?

A. It would be. I should hesitate very much to question a conclusion at which he arrived until I had made a very thorough investigation of the facts on which it was based.

Q. Even then, would the fact that Mr. Haskell had reached one conclusion and you reached another, cause you to pause?

A. It would, until I had checked my work and satisfied myself that my conclusions were correct.

Q. Of course, as a matter of fact, Mr. Haskell in the measurement of large streams has had actually more variety of experiences and a more extended experience than you have had, has he not?

A. Yes, sir, that is entirely correct.

Q. And also in handling the observations which have been made, and in drawing conclusions from them, he has had a long record of work in that line, has he not?

A. He has a long record of work in that line, yes, sir.

Q. He is regarded as accurate, painstaking and very thorough, isn't he?

A. Very.

Q. Mr. Williams, you are also familiar with the work of Mr. Sabin, are you not?

A. I am. Mr. Sabin and I were college mates. We began our professional lives together, roomed together on our first job, and have had a very intimate acquaintance ever since.

Q. He has had long experience in connection with measurements of this kind?

A. I think he was the pioneer in those measurements of the later date.

Q. He had to do with the measurements on the St. Clair River?

A. He made the original measurements on the St. Clair River.

Q. He was Secretary of the International Waterways Commission?

A. Yes, sir.

Q. He built the Soo Lock?

A. He is building it.

Q. Building it?

A. The new lock.

Q. He has had as wide, if not a wider experience, in measuring water in the large streams than Mr. Haskell, has he not?

A. Well, that is more or less of an open question.

Q. Well, they are pretty well up?

A. Let me explain: The work of Mr. Sabin was all done under the direction of Mr. Haskell. Mr. Haskell before that time went through the elementary steps of stream gaging and got to the point where he no longer went out and listened to the tick of the meter, or read the register; and Mr. Sabin had immediate charge of the St. Clair measurements, and in my judgment he did a very excellent piece of work.

Considering that he had no previous experience; that there had not been two or three years of stream gaging going on in the development before he took hold of it, he I think handled that work and got results which are highly creditable to him. Mr. Sabin had had some experience in hydraulic work on the St. Mary's River, but the conditions there were quite different from those that were encountered on the St. Clair.

Q. Have you before you the report of the International Waterways Commission for the year 1910?

A. Yes, sir.

Q. I wish you would turn to page 10 of that report, paragraph 7. I call your attention to the following statement: "Actual values assigned to rainfall and evaporation are not well determined and cannot be used. It is of relative value and it has elements which it is necessary to know, and that value is found in the discharge measurements." In your opinion as an engineer is that opinion true or untrue?

A. So far as the statement that they cannot be used is

concerned, it is incorrect. So far as the statement that they are not well determined is concerned, it is in a measure correct, depending upon what you consider as the limitation of "well determined." Concerning the statement that the value is found in the discharge measurements, I would raise the question that it would be found there if the discharge measurements were accurate. If they are not accurate, then it is not found there.

Q. And the relative value of the elements which it is necessary to know would be in proportion to the percentage of accuracy of the observations, is that your opinion?

Mr. Austrian: Necessary to know for what purpose?

Mr. Wilkerson: To determine the water levels.

A. My answer is no.

Q. Well, would it have any relation to the degree of accuracy of the observations?

A. Not necessarily. There might for example be some condition that it was absolutely necessary to have, and still you might know nothing about it; and I think there are some such conditions involved in the problem that we are dealing with.

Q. That opinion is the opinion of Mr. Haskell, is it not?

A. I don't know whether it is or not.

Q. His name is signed to this report?

A. I see Mr. Clinton's name signed to that report also. Mr. Clinton is a distinguished attorney, whose principal practice has been in maritime law.

Q. And you think that Mr. Haskell's name to that report is entitled to no more weight upon an engineering proposition than the opinion of Mr. Clinton?

A. I think that it may be questioned whether Mr. Haskell would state that proposition in exactly those words; and if he does not state it in exactly those words, it does not mean exactly what it does here. The general interpretation that would be put upon that by a casual reading would undoubtedly be subscribed to by Mr. Haskell, and as a matter of casual reading I would subscribe to it myself. But where we come to specifically consider the meaning of the words involved, I do not agree with it—I would not say what anybody else would do.

Q. I direct your attention to page 84 of that report of the International Waterways Commission and ask you whether you observe the name there, "E. E. Haskell, member American Section?"

A. I do.

Q. That is signed to a document which is entitled "Appendix," which commences on page 23 of the volume in which that report appears?

A. Yes, sir.

Q. Now I direct your attention to page 76 of the Appendix, signed by Mr. Haskell. You have no doubt, have you, that Mr. Haskell intended to certify as an engineer that in his opinion the diversion of 10,000 cubic feet of water would result in a lowering of the level of Lake Erie of 5⅛ inches, have you?

A. Mr. Haskell, testifying in this case, at a date not far different from that at which this report was signed, and saying under oath that the lowering of Lake Erie in inches by the diversion of 4,000 cubic feet per second at Chicago would be two inches, which statement appears on page 56 of the continuously paged record, and saying later in his testimony that the same proportion would apply—or saying in answer to a subsequent question that the same proportion would apply on 5,000, 6,000 or 10,000, and a diversion of 10,000 cubic feet per second on this basis representing 5 inches, I am somewhat in doubt as to whether he meant to say that a diversion of 10,000 cubic feet would represent 5⅛ inches when he signed this report.

Q. From both the report and the testimony, you have no doubt he would fix that figure at five inches, have you?

A. In his testimony he did fix it at five inches, and I assume that he did it knowingly.

Mr. Austrian: On the same basis, in the report he fixed it at 5⅛ inches, and you must assume that he did it knowingly?

A. Allow me to say in justice to Mr. Haskell, that Mr. Haskell's testimony was taken on February 17, 1909, and this report is dated December 4, 1909, so that he may have changed his mind in the interim.

Mr. Wilkerson: To the extent of ⅛ of an inch?

A. Yes.

Q. Isn't it pretty clear to you Mr. Williams that his statement in his testimony about the two inches is a good deal like some of your statements, an approximate statement of the effect in round figures, as nearly as possible?

A. I think that Mr. Haskell would be very careful about making any other statements.

Q. You have spoken about Mr. Haskell and Mr. Sabin and their work in connection with these measurements. What do

you know about the work of Mr. Shenehon? You are familiar with his experience, are you not?

A. I am to a considerable extent.

Q. I want to know whether you are familiar with the extent of the work he has done in this case?

A. I think I am. Mr. Shenehon was connected with the United States Lake Survey and the United States Engineer Office for many years; was intrusted with responsible charge of important work at various times, particularly with the Niagara and St. Lawrence gagings. On the resignation of Mr. Haskell from the Lake Survey to accept the position of Director and Dean of the College of Civil Engineering, Cornell University, Mr. Shenehon then became his successor as Principal Assistant in the United States Lake Survey; and I have frequently expressed my regret that circumstances were not such as would have made it desirable for Mr. Shenehon to remain in the service of the Lake Survey Office.

He was called to a position at his alma mater as Dean of the Department of Engineering, or College of Engineering, for which position I had the pleasure of giving my most cordial endorsement as to his qualifications.

Q. He had to do with work on the St. Lawrence River?

A. He had been engaged on the St. Lawrence River. I am not familiar with the detail of his work there, though from his superiors I had heard very commendatory reports of his performance of such duties as had been left to his execution.

Q. And in connection with the investigation relating to the preservation of Niagara Falls, what do you know about that?

A. That was one of his pieces of work in connection with the Lake Survey.

Q. And the measurements of the Niagara River?

A. And the measurements of the Niagara River, than which, I say again, there is not on record a more carefully conducted series of investigations in natural science.

Adjourned to Saturday, July 19th, 9:45 a. m.

Saturday, July 19, 1913, 9:45 a. m.

GARDNER S. WILLIAMS resumed the stand and testified further as follows:

Mr. Wilkerson: On yesterday, I directed your attention to a statement appearing on page 10 of the report of the International Waterways Commission for the year 1910, relating to the values to be assigned to rainfall and evaporation. And I called your attention to the fact that that report was signed by Mr. E. E. Haskell. In the answer which you made to the question that I put to you on yesterday, did you have in mind the following testimony given by Mr. Haskell in this case on the 16th of February, 1909, on page 67 of the deposition as filed in this case? I read: "I want to ask your opinion regarding the propriety of using any existing data in regard to evaporation, in the attempt to detect the presence or absence of the effect already produced on the lakes, by the diversion made at Chicago since 1909."

A. Are you sure about that paging. I have the reference all right, but according to my notes that is page 53. Is the paging the paging of the continuous record?

Mr. Adcock: You better follow that.

The Witness: I have referred everything here to the continuous paging.

Mr. Wilkerson: I will state parenthetically the portion of the testimony now referred to appears on page 67 of the deposition as filed in the case, and on page 53 of the record as it has been made up and paged continuously. "A. It is hardly permissible to use that data at the present time. Have you any knowledge as to how large the errors in those figures would be? Mr. Williams (Counsel for the District): I object to the question on the ground it is manifestly beyond the range of human knowledge to know, if they are not worthy, how unworthy they are. A. Do you wish me to answer? Q. Certainly. A. I should think one might easily get into an error of 20 to 25 per cent. Q. Now, the same question in regard to the precipitation, on the drainage of the Great Lakes? A. Precipitation is a great deal better known. I think it is safe to say that the observations of the Weather Bureau is given within 12 to 15 per cent., that is particularly the observations made during the later years."

My question is, did you have that in mind when you answered that on yesterday?

A. I would like to have the question that was asked yesterday and the answer read. I do not recall just what I did have in mind.

(Question and answer requested by the witness were read as follows: "Q. And you think that Mr. Haskell's name to that report is entitled to no more weight upon an engineering proposition than the opinion of Mr. Clinton? A. I think that it may be questioned whether Mr. Haskell would state that proposition in exactly those words; and if he does not state it in exactly those words it does not mean exactly what it does here. The general interpretation that would be put upon that by a casual reading, would undoubtedly be subscribed to by Mr. Haskell, and as a matter of casual reading I would subscribe to it myself. But where we come to specifically consider the meaning of the words involved, I do not agree with it—I would not say what anybody else would do.")

The Witness: I had in mind Mr. Haskell's testimony.

Q. I direct your attention to a chart marked in this case: "Haskell's Exhibit 1 for Identification 2/17/09," and to your testimony on yesterday in which your attention was directed to the statement on page 76 of the report of the International Waterways Commission concerning the effect of the diversion of 10,000 cubic feet of water per second upon the level of Lake Erie, and ask you whether or not in the answers which you made relating to that subject you had in mind the testimony of Mr. Haskell appearing in the deposition to which I have above referred, beginning on page 82, and in the continuously paged record page 63, as follows:

"Q. And your testimony is based upon the computations made by you from the plate which you hold in your hand? A. Yes. Q. And used by the International Waterways Commission? A. Yes. Mr. Williams: Now I would like to have that plate marked as Haskell's Exhibit for Identification and attached to the deposition so we will have it. Plate marked Haskell's Exhibit Number 1 for Identification 2/17/09 H. J. R. X Ex."

A. The question is what?

Q. Whether you had that in mind?

A. I had.

Q. I ask you whether or not you do not find that the increments which are marked on "Haskell's 1 for Identification" to which I just directed your attention, and which was identified by the witness as above stated, correspond with the in-

crements appearing on Table XXIII of the same Appendix to the report, in which Table XXXVII referred to on yesterday appears?

A. I do.

Q. I wish you would take the increments appearing on Table XXIII on page 53 of the report of the International Waterways Commission, for the St. Clair, Detroit, Niagara and St. Lawrence Rivers, and reduce those increments to the corresponding loss of level of lake surface, in inches?

A. For 10,000 cubic feet?

Q. For 10,000 cubic feet.

A. What is the particular one you want reduced?

Q. Commencing with the St. Clair, Harbor Beach.

A. You want them all, or the mean?

Q. All stages.

A. The first one given as a mean. As the result of the division of 10,000 by 18,900, I read from Barlow's Tables, .5291005.

Mr. Austrian: That was for St. Clair?

A. That is for the mean stage of St. Clair, according to the table in the International Waterways report.

For the division of 10,000 by 16,300, I read in Barlow's Tables .613.

Q. What is that for?

A. That is for the elevation from 579 to 580, for elevations of Lake St. Clair.

Mr. Austrian: You are asking for all those?

Mr. Wilkerson: Yes.

A. For the division of 10,000 by 17,500, I read .571.

For the division of 10,000 by 19,100, I read .524.

For the division of 10,000 by 20,900, I read .478.

You do not wish anything about the Detroit?

Mr. Wilkerson: Yes, go right down, because I have some other questions that may make it convenient for you to have those right before you for your own computations.

A. For the division of 10,000 by 20,600, I read .485.

For the division of 10,000 by 18,300, I read .546.

For the division of 10,000 by 20,900, I read .478.

For the division of 10,000 by 22,500, I read .444.

Coming to the Niagara:

For the division of 10,000 by 23,400, I read .427.

For the division of 10,000 by 19,600, I read .510.

For the division of 10,000 by 21,400, I read .467.

For the division of 10,000 by 23,200, I read .431.

For the division of 10,000 by 25,100, I read .398.
Coming to the St. Lawrence:
For the division of 10,000 by 28,100, I read .356.
For the division of 10,000 by 26,800, I read .373.
For the division of 10,000 by 27,600, I read .362.
For the division of 10,000 by 29,300, I read .341.
For the division of 10,000 by 29,800, I read .336.
Please reduce those to inches.

A. You want them all, or do you want the maximum, minimum and mean?

Q. No, I would like to have them all.

A. The first value given for the St. Clair gives 6.33 inches.

Q. Give it the nearest eighth, quarter or half.

A. I would say approximately for St. Clair mean increment 6⅜; for the minimum increment 7⅜.

Next I would make 6½; the next 6¼, and the last on the St. Clair 5¾.

Mean for the Detroit about 5⅞, minimum 6½, the next 5¾, 5⅜. 5½, that is mean for Niagara. For the minimum increment of Niagara 6⅛; the mean is 5⅛; minimum 6⅛.

The next is 5⅜.

The next is actually about 5 3/16. The last one, that is the highest increment for Niagara 4¾, and the St. Lawrence the mean is 4¼; minimum is 4½.

The next 4⅜; the next 4⅛; the last 4 inches.

Q. It is a fact, is it not, that the effect upon the level of the lakes for the diversion of a given quantity of water is greater at low stages of the lake than it is at high stages of the lake?

A. Yes.

Q. I call your attention to your Table Number LXV?

A. Yes.

Q. The same being table of elevations and mean elevations of lakes, 10 years prior and for ten years subsequent to the opening of the Chicago Drainage Canal?

A. Yes, sir.

Q. The figure which you have put down there for the mean elevation of the lakes, the mean elevation of Lake Michigan from the year 1890 to the year 1899, is 580.342?

A. That is from 1890 to 1899?

Q. Yes. That represents a stage how much lower than the mean stage as stated in Table Number XXIII?

A. Substantially 13 inches, a foot and one-tenth.

Q. So that if we were to take the figure from Table XXIII which applies to the conditions represented by an average of

580.342, that would take the figure 580.581, which would be 6⅞ inches, would that not, approximately?

A. That is according to the table.

Q. I am speaking according to the table?

A. Yes.

Q. Now take the St. Clair elevation, the mean is 575.013 if we were going to take a figure which would represent that condition, we would take——

A. You ask what I would take from this table?

Q. Yes.

A. From Table XXIII for the elevation of Lake St. Clair, I would split the record from 574 to 576 and call it 19,600 for the increment, which would be 6⅛ inches.

Q. Now take the Erie elevation of 572.012.

A. That is the same situation that we had before, and I would call that 5⅝.

Q. So far as these figures in inches are concerned, the figures for the mean as you have stated them for the period 1900 to 1909 would not be substantially different?

A. No, you would reduce—that is depending on reading from this table, one would naturally reduce the effect slightly on St. Clair and Erie, that is having gotten well up into that foot by reading from this table, a person would hardly split, but the results would be substantially the same.

Q. So that in arriving at the real effect which must be kept in mind for the purpose of the inquiry which we have here, it is necessary to take into consideration the effect of the given diversion at the low stages of the water, is it not?

A. That is contrary to the testimony of every witness in this case, they all having specifically stated that for the purpose of this investigation the increment could be represented by a straight line, which means that the increment for the purposes of this case and for the range covered by it is substantially the same at all stages.

Q. I am speaking of the effect of the lake level as the result of the diversion of a given quantity of water. I think you misunderstood my question.

Mr. Adcock: In other words your proposition is there might be some slight difference between high and low stages?

Mr. Wilkerson: What I have in mind is this: That the effect of the diversion of a given quantity of water would be greater at the low stages of the lake. That is a fact, is it not?

A. Theoretically.

Q. Yes, theoretically it is greater and practically so.

A. Let me make this correction to my previous answer, where I said every witness answered, make it: Every witness of whom the question has been asked.

Mr. Adcock: That is they did not make any distinction so far as this case is concerned?

A. That is it, for the purpose of this investigation, for the line covered in this investigation.

Mr. Wilkerson: Without regard to what these other witnesses have said, it is a fact that for the low stages, you have to increase the figures showing the effect upon the lowering of the lakes to an extent as indicated by the figures which you have given.

A. Not at all.

Q. I am speaking of the table itself.

A. Oh.

Q. I am not asking whether in your opinion the table is inaccurate, because of course you have said the engineers are wrong. I am asking you to assume the accuracy of the figures which have been prepared by the Government Engineers.

A. I did not understand that assumption to be included in your question.

To state an answer formally to your question, I would say this: That according to the table which is presented on page 53, and upon theoretical conditions which I believe to be accurate conditions the effect of a diversion at the elevations existing from 1890 to the present time would be greater than the effect of a diversion at the elevations which are presented as the means in Table XXIII of the report of the International Waterways Commission on Lake Erie.

Mr. Adcock: That is the mean for the entire period?

A. No, what they state here as the mean. That is a fair answer to your question.

Mr. Wilkerson: By mean stage as used in this table is meant the mean from the year 1860, isn't it?

A. I can't say as to that for the moment. I think that it is, but it does not make any difference whatever that mean is, it is higher than the stages that have existed since 1890 to the present time.

Q. I understood you to say it was your opinion that the effect of excavations which had been made in the Detroit and St. Clair Rivers has been to permanently lower the levels of Lakes Michigan and Huron by about a foot, .6 of a foot to a foot?

A. Six tenths to a foot I think was my estimate with possibly one foot and .2.

Mr. Adcock: You mean under the conditions as they exist now, as far as "permanently" is concerned.

Mr. Wilkerson: I mean assuming that condition remains as it is, it would be the effect of it according to his testimony.

Q. Now what are the influences which in your opinion have a tendency to reduce the actual mean level of the lakes?

Mr. Adcock: You mean to reduce them or affect the levels?

Mr. Wilkerson: To reduce, I said.

A. You mean other than the deepening of the channels?

Q. Yes.

A. The clearing of the lands on the water sheds of the tributary areas and the diversion of water at Chicago; and of course the levels of the lakes are subject to variation, on account of variations of rainfall and evaporation.

Q. Is it your opinion that the effect of the removal of the forests and cultivation of the soil is to diminish the quantity of water which flows into the lakes?

A. No, sir.

Q. And thereby reduce the level?

A. No, sir.

Q. What do you have in mind?

A. It increases the rapidity of the discharge into the lake and gives it an opportunity to get out of the lake more rapidly, so that the low water is lower.

Q. And that is the process of reasoning by which you reach the conclusion that it does have a permanent lowering effect?

A. That is the process by which I arrive at that conclusion.

Mr. Adcock: Do the extensive drainage operations have anything to do with that?

A. I had that in mind also in my answer, whether I stated it specifically or not, that with the cutting off the forests comes the cultivation of the land, all of which tends to increase the rapidity with which the water reaches the lakes.

Mr. Wilkerson: You stated, Mr. Williams, that no one had been absurd enough to suggest an increment of 16,000 for Lake St. Clair?

A. I said less than 16,000, I think.

Q. You do find in Table Number XXIII an increment of 16,300 feet?

A. I do.

Q. Stated for the stage 579.580?

A. I do, but that is not an average stage, not an average increment, however, and it is not within the range of my answer, either, as I said less than 16,000.

Q. You have produced in evidence a number of charts, plates and tables.

Mr. Adcock: You are referring to all of Williams Exhibit 34?

Mr. Wilkerson: Referring to a compilation which we have been designating as Williams Exhibit 34 in this case.

Q. About when did you begin the preparation of these tables, charts and plates?

A. As soon as Mr. Shenehon's evidence was presented, or in fact while it was being presented, that being the first opportunity we had to get any reliable information, or information which we understood would be accepted along the line of evidence bearing upon these problems.

Q. Were most of these tables, plates and charts prepared about the time he testified?

A. Oh, no.

Q. They were prepared some time afterward?

A. From that time until a few days ago.

Q. When did you prepare the first table in which you made use of the method of referring the discharge measurements to a different elevation of the lake from the method which had been employed by the Government Engineers in that respect?

A. I don't understand the intent of your question. I don't understand what you are trying to get at.

Q. (Question read.) I am referring now to the tables in Exhibit 34, and you have a series of tables there in which you have corrected, as you say, the stage to which the discharge measurements are to be referred.

Mr. Austrian: Don't you think you ought to separate that question?

Mr. Adcock: You ought to designate the tables.

The Witness: You are referring to the tables of the discharge of the St. Clair River.

Mr. Austrian: The question is involved, incorporates two questions in one.

Mr. Wilkerson: I think the witness understands what I want.

The Witness: You are referring to the St. Clair River, are you?

Mr. Wilkerson: Any river.

Mr. Austrian: Just give him one table for example. When

did you prepare the first table that is computed upon the basis other than that employed by the Government?

Q. (Question read as follows:) ("When did you prepare the first table, in which you made use of the method of referring the discharge measurements to a different elevation of the lake from the method which had been employed by the Government engineers in that respect?")

A. That question really, Mr. Wilkerson, I must say is not clearly intelligible to me. I think it is possibly my fault; that I do not understand the terms that you are using. I will be very glad to do my best to answer the question for you if you will tell me what you are trying to get at.

Let me ask if this is what you mean: Do you mean to ask when it was that I first began the investigation of the effect of the discharge based upon what I have considered normal conditions since 1890?

Q. When you prepared your first table, which is of the same kind as table number——

A. You mean something in the nature of Table XXIX?

Q. (Question re-read.)

A. If you mean by that when did I first combine the observations in consecutive groups, for the purpose of comparing them with the lake elevations existing over a period of several days, that work was done during the summer of 1909, or immediately following the conclusion of Mr. Shenehon's examination.

Q. Were the tables which have been produced in this case prepared then?

A. Some of them were.

Mr. Austrian: You mean all the tables?

Mr. Wilkerson: Which ones were prepared as early as 1909?

A. Table XXVIII was prepared at that time.

Q. Any others about that time?

A. Oh, yes, there were a large number of them.

Q. I would like to have the ones that were prepared in 1909.

A. Table 1 was prepared at that time. The table of which this print is made is a redrawing of it due to the fact that the sheet became damaged. Table II, I think is a print of the original table.

Table III, Table IV, Table V, Table XIII, XIV, XV, XVI, XVIII, XIX, XXII, XXIII, XLI, XLII, XLV, XLVI. In this answer, I must be allowed to extend over into 1910, because I

cannot exactly distinguish between what was done in 1909 and 1910.

Q. I understand you to say it takes in 1909?

A. No, and I am giving you the tables here of those that were prepared in the first investigation of the subject, after Mr. Shenehon's testimony was presented, and that covered the balance of 1909 and some work in 1910.

As we went on with the work, we found we wanted additional information and we asked for it, and got information that was not put in the record at the time that Mr. Shenehon testified.

Q. You have some idea; I want the order in which you did this work.

A. I am giving this to you. The work on this embraces, you might say, three periods, leaving out an amount of preliminary work that was done before any testimony was taken in the case, which was based upon solely what might be found in reports, and was not at all conclusive.

The testimony of the complainant closed on June 5, I believe, 1909, or rather, the testimony of Mr. Shenehon closed June 5, 1909.

Mr. Austrian: That is the same thing.

The Witness: No, they examined Mr. Coulby after that. And we immediately began work on this data and continued until along into 1910. Then there was a cessation of activities, and quite a lapse of time which I do not recall, until the matter was stirred up again, and some further investigations were carried on. And then finally last fall the matter came to a head a third time and we proceeded to make further investigations, or to complete, rather, the investigations that we had under way.

As a matter of fact, when the need for the work had apparently disappeared temporarily at least, we having numerous other things to attend to, we simply shelved it in our office and left it for future study.

Mr. Austrian: Then the numbers you are calling off are the numbers prepared in the second period?

A. No, first period.

Q. And that centered in 1909, along in 1910?

Mr. Wilkerson: Along into 1910.

The Witness: Table XLIX, the first sheet of Table XLIX, and the first sheet of Table L and the first sheet of Table LIII; I might also say in regard to Tables XVIII and XIX, that the original table—that the portion of that actually presented here which was compiled during this first period of

investigation as represented on the first sheet of those respective tables, that the second sheet has been re-drawn to extend the observations to 1912. The original sheet stopped in 1908 and we simply copied the preliminary portion of the sheet and added to it what is necessary to bring the information to 1912.

Q. Were any of these tables you prepared in 1909 and 1910 ever submitted, either to the Secretary of War or the Chief of Engineers, in connection with any matter there pending relating to the Sanitary District?

A. Not to my knowledge. It is possible that there might have been, as copies—well, I won't be sure whether a copy was in the possession of anybody who may have submitted it.

Q. You were never called upon to make a statement or any explanation to accompany those tables, to be presented to the War Department?

A. No.

Q. I direct your attention to Table XLV a, consisting of five sheets.

A. Yes.

Q. When was that table made?

A. That table as presented here was made recently, at the request of Mr. Shenehon. It was copied from a table made in pencil, which was made in 1909. We simply had the thick paper with its computations in pencil. We did not regard that as of sufficient importance to introduce ourselves, but when they were asked for we had them copied in blue prints.

Q. Have you utilized this table in deriving an increment as to which you have given evidence in this case?

A. That table is the basis, I believe, of Table XLV.

Q. I direct your attention to sheet 2 of that table and to group 5, and ask you to state the dates on which the observations which are there utilized were made?

A. Group 5?

Q. Yes?

A. The date would indicate that they were made in February. I suspect that that, too, is an error.

Mr. Shenehon: That is correct.

The Witness: Were they made in February?

Mr. Shenehon: Yes.

The Witness: I have forgotten that there were observations made in February.

Mr. Wilkerson: What is the answer?

A. I say the date would indicate they were made in February.

Q. February 14, 15, 16 and 17, 1899?

A. Yes.

Q. If you have any doubt on this subject, I ask you to refer to the tables from which observations 93 to 102, inclusive, were taken.

A. I haven't any doubt. The thing that I had forgotten was that observations were made in February. Yes, that is all right.

Q. To what tables are you now referring?

A. I will have to get my copy of it so as to see what that exhibit is.

Mr. Adcock: I think that is Williams' Exhibit 24.

A. Williams' Exhibit 24.

Mr. Wilkerson: These observations on which the conclusions are stated, as the result of which this table was made, were picked out by you with particular care, were they not, Mr. Williams, so as to get observations which would represent the normal conditions?

A. They were picked out with reference to the mean elevation of Lake Erie for the days during the observations, as indicated in the record of the Buffalo gage.

Q. And for open season conditions?

A. For the conditions which existed when the observations were made. I don't know whether the river was open, or closed with ice, but I assume it must have been open.

Q. You do not understand that in reaching a result with reference to this increment, it would be proper to include observations taken when the river was closed with ice, do you?

A. Not for direct comparison with those for the open season, no.

Q. Now, I call your attention to the note at the bottom of Table Number 1: "Summary of discharges International Bridge Section Niagara River," and to the following.

Mr. Adcock: You are referring to Exhibit 24?

Mr. Wilkerson: The same being Exhibit Number 24 as follows: "Numbers 116, 117 and 118, span 1 blocked with ice. 114, span 9 blocked with ice. 91, 92, 100, 101, 102, spans 1 and 9 blocked with ice. 93 to 99 inclusive, spans 1 and 9, and east half of span 2 blocked." I will ask you whether or not those notes do not indicate to you that there was ice in the river at that time?

A. They indicate that to my mind at the present moment, yes, sir.

Q. In your opinion as an engineer, do you regard it as proper to incorporate those observations taken in February, 1909, with the open season observations with which they have been incorporated?

A. Well, that is an error which escaped my attention until this moment. I may say—

Q. Do you know now whether as a matter of fact you have used these observations in which the river was blocked with ice in any other comparisons which you have made?

A. I presume that they have been used in all of them, as all of these comparisons with gages have been based upon this same table.

Q. Were any of those used in Table Number 3?

A. In Table Number 3?

Q. In which you have made a criticism of the Niagara work, comparing its accuracy with the work on the St. Clair and the St. Lawrence Rivers, having derived the average variation from the mean?

A. So far as I see, this table of comparison of observation 83 with observation 116 would be an unfair comparison, for the reason that in 116 span Number 1 was blocked with ice, whereas in 83 it was not. Let me go through these and make sure that there are not any more.

Q. How about 18 and 121?

A. Apparently there is nothing to indicate that there was anything wrong with 121. Am I right, Mr. Shenehon? I do not see it here in the notes.

Mr. Shenehon: The date indicates it.

Mr. Wilkerson: March 24th?

A. You specifically state what is the matter with these various ones, and omit 121. I simply want this for my own protection, that is all, that so far as the notes on Exhibit 24 are concerned, there is nothing there stating that there were any abnormal conditions in the case of measurement 121. It is, however, a fact that that observation was taken on the same day as observation 120, which states that the discharge for span 2 was interpolated, and the measurement 119 which states that the discharge for spans 1 and 2 was interpolated.

Q. Referring to the comparison based upon the use of observations Number 83 and 116, I direct your attention to the fact that the per cent. of variation from the mean which you get by reason of the use of that observation 116, is 5.27 per cent.?

A. Yes.

Q. State whether or not that would not indicate to you

that the improper use of these ice observations has been an important factor in getting the figure of 2.89 as the summary of the—

A. It is entirely correct that that comparison should not have been included in this table; and it was included through a neglect on my part to take cognizance of this note at the foot of this discharge table, and to that extent—

Q. Or the date?

A. Or the date. That was a clean oversight, and the average variation as shown in this table should be reduced by the effect of eliminating that 5.27, shown by the comparison of observations 83 and 116.

There may be another one here, Mr. Wilkerson. Let me be sure.

Q. There are observations 112 and 92?

A. 112 and 92 were both under ice conditions. Whether the conditions were the same or not—there is nothing in the note apparently to indicate directly what the condition in 112 was, and we may or may not assume that it was similar to the conditions in 116 or 102. If similar to 102, it is similar to 92.

Q. Of course, the open season conditions, it would not be proper to use either one of those observations, would it?

A. Yes, for this purpose, we are not considering whether it was open season or closed. What we are endeavoring to do is compare observations under similar conditions. These observations 112 and 92 would compare with each other. They are not compared with any others—

Q. Did you use the same method on the St. Clair, incorporating winter observations?

A. On the St. Clair we took into consideration all the observations that had been introduced in the testimony and we compared those that had been taken under what the evidence indicated, as we understood it to be, similar conditions.

I am perfectly frank to say right here, gentlemen, that I based these comparisons on similar stages, and overlooked the fact that these were winter observations. I am perfectly frank to say that, and I am very glad my attention has been called to it; and I will have this table corrected to eliminate observations in which comparisons are made under conditions which are not similar. I will be glad to sit down with Mr. Shenehon and ask him to assist me in selecting the ones that do represent similar conditions.

Q. So that any place in which these tables have been used as the basis of conclusions reached in this case, the conclusions which have been reached and the use which has been

made of them, so far as their effect upon other witnesses is concerned, will be subject to the correction of these tables by the elimination of these observations.

A. They will be subject to that correction.

Mr. Adcock: You say the elimination of the observations?

A. Oh, no, they will be subject to a correction to meet the action conditions. If during a winter measurement when the conditions were the same on two days, we have these variations, then they are entitled to be in here. But it is not right to compare a case when we had spans blocked with ice with a case when we did not; nor is it right to compare cases when only one span was blocked with ice with cases where more than one were blocked with ice.

Q. As a matter of fact, aren't the conditions such in the winter season that it is regarded as improper to use the winter observations for any purpose, in comparison or otherwise; the ice conditions changed so from time to time. There may be ice around the Niagara Falls?

A. I will answer that question by asking, then, why the Government wasted the money to take them if they are improper to use for any purpose?

Q. I think I referred to Table Number 3, as to the use which was made of that as to the correction which would have to be made, and I applied it also to Table XLV a. If I did not, I ask you whether that is true as to Table XLV a, also?

A. It is.

Adjourned to Monday, July 21, at 10:30 a. m.

Monday, July 21, 10:30 a. m.

GARDNER S. WILLIAMS resumed the stand for further cross-examination by Mr. Wilkerson, and testified as follows:

Q. Referring to the increment of the Niagara River, Mr. Williams, is it a fact that in deriving that increment you utilized the principle of the ratio of increment to fluctuations of lake surfaces over periods of years?

A. You mean the increment as testified to finally, the value of 34,000?

Q. I mean in your computations of the increment for this river, did you make use of that principle in any of the tables which have been presented by you?

A. It was not used in connection with any tables from

XLV to XLVII a, inclusive. It was used in getting at the value which I finally adopted as being the most likely, or as being a probable value.

Q. I will ask you to explain how you made use of the principle of the ratio of increment to fluctuations?

Mr. Adcock: What fluctuations do you refer to, oscillations?

Mr. Wilkerson: To the fundamental proposition on which that principle is based.

Mr. Adcock: You mean the monthly, yearly or daily?

Mr. Wilkerson: Well, a given period.

Q. If you will, explain that to us first in a general way, and then take it up by reference specifically to your tables; it might be clearer?

A. I will have it for you in just a moment. The general principle involved is that if any reservoir, or if rather, two reservoirs, have openings of different sizes and water flows into both of them in amounts varying, that the one which has the opening with the larger increment will change its level less than the other for the same quantities of inflowing water, or the same rate of inflow.

Q. And it is your opinion that this proposition is applicable to the Great Lakes, treating them as water reservoirs, as you have stated?

A. It is.

Q. The proposition is still applicable where the quantities of water are different, as in the case of the three lakes we have under consideration here, is it not?

A. Yes, it is still applicable.

Q. Except that you have to make allowance for the difference in quantity. The proposition remains the same. Do I state that correctly?

A. Yes, that you must take into account the difference in quantity.

Q. The difference in quantity of water, but that, making allowance for that, the general proposition applies?

A. (No response.)

Q. Now, coming back to the use which you made of it in this case, I will ask you to explain a little more in detail by reference to the tables which you have submitted, in just as simple a way as you can, just what use you have made of them, having in mind that this case is to be argued by lawyers and heard by a judge?

A. Take, for example, Table XXI, we find that if the elevations of Lake Huron, for instance, be plotted as ordinates

to the elevations of St. Clair abscissas, that they fall in a line, or they approximate to some sort of a line; and that if the mean line be constructed a ratio will be derived for the fluctuation of one lake in terms of the other, as testified to by the complainant's witness Shenehon, page 592 of the continuously paged record, that when Lake Huron goes up a foot Lake Erie goes up .7 of a foot. This is more specifically explained previous to that, but that happens to be the reference I have a knowledge of just now.

Q. In your own opinion, that portion of his testimony is correct, is it?

A. Based upon what he was stating, that is, upon the average results extending from 1860 to 1908, which I understand is what was included in the basis of his answer, I think agrees substantially with the results which we have obtained.

Mr. Austrian: On that point.

A. On that point. Then if for the same quantity of water flowing in to both Lakes Huron and Lake Erie, Lake Erie is raised .7 of a foot as Lake Huron is raised a foot, it means that the increment of Lake Erie must be to the increment of Lake Huron inversely as the changes, or as 100 to 70.

If in addition to that, there is a further inflow into Lake Erie not accounted for or not received through the outlet of Lake Huron, then the indication would be that the increment of Lake Erie must be still larger, as it has to take care, not only of the water coming from Lake Huron, but such as comes from its natural drainage.

Mr. Wilkerson: Now, you spoke of plotting these elevations. If when you plot the elevations of these two lakes, in the way in which you have stated, they tend to arrange themselves in a line, is that an indication to your mind that the relation which is represented by that line is the correct relation for the observations used?

A. That line is a correct representation of the relations between the observations used, considered as a whole.

It must be borne in mind that by taking short periods, different results are obtained than in the case of long periods; that individual years may show apparently erratic indications, but for a general relation covering the period considered, that line indicates the ratio of one change to the other, based on the whole period. It might be a straight line, of course, or it might be a curve. For the purpose of this case the straight line has been utilized.

It is entirely possible that a final analysis might show that at high stages the relation between the fluctuation was differ-

ent from what it is at low stages. But that was a phase of the matter that has not been considered up to the present time; and I question very much if the information we have is sufficient to arrive at any satisfactory conclusions along that line, because the observations do not cover a sufficiently long period; and are influenced by changes in the conditions of the discharging channels.

Q. That last statement has to do with the curvature of the line?

A. Yes.

Q. And not to the establishment of the law?

A. No, that deals with the question of curvature of the line.

Q. I understand it to be the effect of your testimony, looking over these tables which have been submitted, that you by a similar process of reasoning worked back from the increment of the St. Lawrence to that of the Niagara, is it?

A. It is.

Q. So that we may have it here, state just briefly, and as simply as you can, your process of reasoning by which you work back from the St. Lawrence to the Niagara?

A. The process is simple; by a plotting of the elevations of Lake Ontario and Lake Erie, and an analysis of the results presented in Table XLIV, we get the relation of the change of Ontario to the change of Erie.

Q. It is there stated at 136 per cent.?

A. Yes.

Q. And you have adopted that ratio, and then combined with it your computations relating to rainfall and evaporation?

A. The tables of rainfall and evaporation, I believe, are not combined with this increment. The treatment of rainfall and evaporation does not involve the fluctuation of the lake surfaces except as actually measured to determine the storage that has accumulated or been lost from one lake to another. It has nothing to do with this relation.

Q. Does not enter into this 136 per cent. at all?

A. Does not enter into that 136 per cent.; at least that is my present recollection.

Q. In the case of this table which you have before you, Number XLIV, do the rainfall evaporation and run-off interfere materially with the operation of that law which is there deduced?

A. The rainfall and evaporation has not been taken into consideration in this table, it being based solely upon the relations of the lake elevations, and this ratio is that which is

shown by the actual changes of elevations, without inquiring as to their cause.

Q. In making this transfer, do you regard it as proper to ignore the elements of run-off, rainfall and evaporation?

A. It is reasonable to make a correction for the effect of local supply, which I assume to be the point that you are getting at.

Q. Yes. But you regard the method as substantially correct, notwithstanding any differences that might result from the rainfall, evaporation and run-off?

A. I would say that so far as this analysis is concerned of connecting the St. Lawrence with the St. Clair that the corrections on the outflow of Ontario due to the rainfall there are of the opposite sign to those that would be applied at Erie. And when those corrections have been made, it is my opinion that you will get to the same result at the St. Clair, substantially. In other words, that the St. Lawrence discharge will check St. Clair as it is in this computation.

Q. You can pass from the St. Lawrence to the St. Clair and also from the St. Clair to the St. Lawrence?

A. Certainly.

Q. According to the method which is stated here?

A. Yes.

Q. It applies eitherway?

A. It applies either way. Of course, you must realize that it is only as approximation, inasmuch as you cannot accurately determine the effect of that local supply. That is the thing that coming in there makes this an approximate comparison.

Q. What, in your opinion, are the limits of the precision, in the method of going from one lake to the other in the way in which you have just explained?

A. If there were no variations of inflow and outflow due to the local supply and local evaporation, the method would be strictly accurate, assuming that the data upon which it is based are accurate; that is, that the ratios are the correct ratios. It will be affected to the extent to which the variations of local supply and local evaporation cause fluctuations of the lake surface in the second lake in the comparison.

Now, as to how much that is, I am not prepared at this moment to say, for the reason that at times the inflow from the local drainage may accentuate the fluctuations, and at other times it tends to suppress them, and considering a long period of years these effects will to a greater or less extent

neutralize, and it would involve quite an extended study for me to be able to express an opinion in a percentage.

Q. Just what is the increment, according to your method, of the Niagara as derived from the St. Clair?

A. I don't recall that I specifically derived the increment of Niagara from the St. Clair. Considering the results of computations both ways from the St. Lawrence and the St. Clair, I arrived at 34,000 as being as low a value as seemed to me reasonable for the Niagara.

Q. The increment of the Niagara as derived from the St. Clair is more intimate, so to speak, than the increment of the St. Lawrence as derived from the St. Clair?

A. I would say not necessarily, for the reason that going through Lake Erie, and Lakes Erie and Ontario, the local supply effects of one balance the similar effects of the other, and I think that the relation between the St. Lawrence and St. Clair increment is more nearly correct than a relation that would be derived from either for the Niagara.

Q. It may be that I do not catch your idea.

A. Perhaps I do not catch the trend of your question, Mr. Wilkerson. I am trying to follow you.

Q. We are working from the increment of one river to that of another. The Niagara River, of course, is much nearer to the St. Clair than the St. Lawrence; and the question was whether the Niagara River stands in your opinion in a more intimate relation, as far as the determination of this increment is concerned, to the St. Clair than did the St. Lawrence, on account of the greater distance?

A. I think, considering all the factors of the problem, that the derivation of the increment of the St. Lawrence from the St. Clair, or the increment of the St. Clair from the St. Lawrence is more likely to be correct than the derivation of the Niagara increment from either one, for the reason, as I stated before, that the local supply effects and local evaporation act in one sense in the case of Erie, and in the opposite sense in the case of Ontario and tend to cancel each other's influences.

Q. Just about how much more nearly accurate do you think you could go from the St. Clair to the St. Lawrence than you could go from the St. Clair to the Niagara?

A. Depending altogether upon the magnitude of the local influences in Lake Erie and Lake Ontario.

Q. Have you in your own mind any opinion that could be expressed in the language of percentages?

A. I have not at this moment.

Q. And what you have said would apply in going back from the St. Lawrence to the St. Clair?

A. Yes.

Q. You think you could go more accurately from the St. Lawrence to the St. Clair than you could from the St. Lawrence to the Niagara?

A. I think your results would be more accurate when you had gotten there, in the former case.

Q. Of course, the method which you have used could be used starting at the Niagara and working either way, provided you had an increment?

A. Yes, if you had an accurate increment.

Q. Which is derived from observations at Niagara?

A. If you had an accurate increment for the Niagara River you could go both ways from that and expect to get reasonable results. If you didn't have an accurate increment, you could work both ways and get unreasonable results.

Q. In deriving the increment of the St. Lawrence River, did you take into account the changes which were produced by the construction of the Gut Dam?

A. I don't see from the dates on the St. Lawrence gagings, as I understand it, that the Gut Dam had anything to do with the situation at that time.

I will correct this answer of mine by saying that I understood that the effect of the Gut Dam was not effective until 1904, as the year 1903 has been included in the table, showing the relative elevations of Lakes Ontario and Erie. If the Gut Dam were influential in 1903, then a very small correction, the sign of which I am unable to state at this moment, would have to be made in that ratio.

Mr. Austrian: For that year?

A. No, the ratio for this whole table; it would be one year out of forty-three.

Mr. Wilkerson: The effect of the Gut Dam was to lessen the flow of the St. Lawrence River for a given stage, about 5½ per cent., was it not?

A. It was to raise Lake Ontario about 5 inches. I don't remember the percentage of that. I think, on recollection, that the 5½ per cent. is approximately correct, as I believe I connected those two figures, that it was substantially the same number of inches as it was per cent.

Q. And that change of 5½ per cent. would have to be made in the increment, in order to give expression to the effect of this dam, would it not?

A. The effect of that dam should be corrected in Table

XLIV. Whatever effect it had in 1903 should be used to reduce the elevation of Ontario for that year.

Q. The thing to which I had reference in my question was the effect upon the increment, and I understand that effect is one which would show itself immediately, or substantially so.

Mr. Austrian: Immediately upon the completion of the dam?

Mr. Wilkerson: Yes.

A. The increment as derived in this testimony and applied is based upon the increment of the St. Clair River, as is shown by the information which was presented by the complainant in this case.

I am not aware that the complainant anywhere in its testimony introduced the subject of the effect of the Gut Dam upon the increment of the St. Clair River—or the St. Lawrence River, or corrected his (Mr. Shenehon's) increments to compensate for it.

With that obstruction it is possible, though not certain, that the increment of the St. Lawrence River now is less than it was prior to the construction of the dam. But there has been since then constructed another compensatory work of a different character, a channel in the vicinity of the Gut Dam, which is shown upon Williams' Exhibit 18 and is there designated at the North Channel. This is a channel which has been constructed through a portion of Drummond Island and is from 17 to 19 feet deep and about 300 feet wide. The Gut Dam closed a channel about 400 feet wide and less than 18 feet deep, and was located within a mile of the North channel. It would seem, therefore, that the construction of the North Channel must have to a considerable extent compensated for the effect of the Gut Dam.

Q. But dealing with the effect of the construction of the Gut Dam is an independent element, in order to determine the effect of the loss of outflow upon the increment, you would reduce the increment by approximately the same per cent. as the outflow was reduced. If you were dealing with that just as an independent factor and wanted to determine what its effect was upon the increment, you would reduce the increment by a per cent. which would be in accordance with the loss of outflow?

A. That would be only true during the period when the lake was re-adjusting itself. When the lake arrived at its new elevation, it is very probable that the increment would be found to have been increased by reason of the probably

broader channels that would be available for the discharge of water on account of higher elevation.

During the period when the lake was rising, the increment would be smaller than it was in the first case, and would gradually approach its final value, which would be either smaller or greater, but probably would be greater.

Q. Have you personal knowledge as to the physical conditions under which the dam was constructed? Do you know the facts about the steepness of the banks and the channels?

A. I saw the dam the other day. It is rather an insignificant structure, cutting off a channel that extends obliquely to the general trend of the current. This new channel opens directly into the main opening of the river through the Galops Rapids, and from that inspection, it certainly appears to me that there can have been very little effect, very little ultimate effect, very little net ultimate effect of the two improvements.

Q. Is there anything further, Mr. Williams, that you care to state about the effect of the construction of the Gut Dam?

A. No response.

Q. But for a given stage, if you lessened the outflow of the river a certain per cent., you would reduce the increment by the same per cent., as a general proposition, and for small variations?

A. Yes.

Q. That is the method which you have accepted as a correct method in this case, is it not?

A. Yes, understanding you to mean that for two given stages, if the outflow is reduced for both of them by a percentage, the increment would be reduced by a similar percentage. That is what you really meant to say, I think.

Q. That is a correct principle, as I understand your testimony, that there is a relation between the outflow and the increment, and where you have a small outflow you have a small increment; and so starting in with the St. Clair, you have a given increment without regard to what it is. When you get to the Niagara you have a little larger one; when you get to the St. Lawrence, you have a still larger one, there being a relation between the amount of the outflow and the increment?

A. There is no such relation. The increment is dependent upon the cross section and slope of the outlet. For example, you might have such an outlet to Niagara that you could have an increment ten times as great as you would have through the St. Clair or through the St. Lawrence.

Q. Or even smaller?

A. Or you could have it smaller.

Q. Now, referring to the three rivers, the St. Clair, the Niagara and the St. Lawrence, I desire to get a summary of your opinion as to the elements of precision with reference to each one of those rivers, or to put it another way, the relative precision of the three rivers; I am referring to those measurements of volume.

A. Measurements of volume?

Q. Measurements of volume that you have under consideration in this case. Let us take first the stability of the lake at the outflow weir, and compare those three rivers.

A. Now, let me get your question clearly in mind. You wish me to express my opinion as to the relative dependence that is to be put upon the measurement of quantity independent of increment of the St. Lawrence, Niagara and St. Clair Rivers. Is that correct?

Q. Well, let us make it the law of discharge.

A. I do not think that the law of discharge has been established. Certain specific measurements of discharge have been made, and I have some opinions as to their relative reliability. But as to the establishment of the law of discharge, I am very clearly of the opinion that it has not been established for any of the rivers. And that is what I had in mind when I said in answer to a question on Friday that I doubted if anyone had successfully measured one of these large rivers; it being the purpose of the measurement to establish the law of discharge. And it is my belief that that law of discharge is not established.

Q. You have spoken in your testimony of certain difficulties which have been encountered in attempting to arrive at this law of discharge, and you have throughout your testimony, you have here and there stated facts and expressed opinions, which have related to those difficulties, related to the degree of credibility to be given to the conclusions which have been reached by those who have thought they could derive the law of discharge with reference to the different rivers. What I would like to have you do is to summarize, if you can, your opinion, having in mind the difficulties which have been encountered, having in mind the effect which you think those difficulties have produced.

I would like to have you summarize your opinion as to the relative degree of credibility which is to be given to these conclusions which have been reached as to the three rivers. And in connection with that I was about to direct your attention to certain particular points as to which I desire you to make the comparisons. Now, do I make myself clear as to

the general line of opinion which I wish to have you express?

A. I think I know what you wish me to express, and I must confess that I am afraid I am unprepared to express an opinion on that subject further than to say that I do not believe the law of discharge of any one of these rivers has been established. The measurement of quantity, I am ready to express opinions on, but the law of discharge means, or involves the connection of the discharges of the river with the other factors which enter into it. The discharge is an effect. The causes of that discharge are to be looked for elsewhere.

Now, the law of discharge must take into cognizance those causes, and up to the present time I feel very sure that the correct relation between cause and effect in the discharge of the rivers flowing from the Great Lakes has not been established.

Q. Well, let us take certain particular points, then: I direct your attention to certain particular points which would appear to be factors to be taken into consideration in arriving at a professional opinion as to the degree of credibility to be given to these conclusions of the Government's Engineers as to the law of discharge of these respective rivers. Now. I would like to have you take the three rivers and compare them from your point of view upon the points to which I have called your attention. Let us take first the stability of the lake at the outflow weir, and take the three rivers.

A. Considering the outflow weir as the point where the gaging measurements were made, I think the St. Lawrence has the advantage.

Q. We will specify the particular points: Lake Huron at the head of the St. Clair River; Lake Erie at Buffalo, and the St. Lawrence near the Galops Rapids.

A. The St. Lawrence has the decided advantage.

Q. I want all three of them compared.

A. The St. Clair ranks next and the Niagara is the most difficult, most unfavorable.

Q. As to the stability of the lake?

A. Well, as to the conditions that are encountered—

Q. I am speaking now of the stability of the water surface at those three points.

A. I think that is correct.

Q. Now, let us take the distance of the gaging section from the lake.

A. The gaging station on the Niagara was the nearest to the lake; the St. Clair would be next and the St. Lawrence the furthest away.

Q. And in your view, what effect does that have upon the credibility to be given to the deductions as to each of the three rivers, that factor alone, and other things being equal?

A. That would be a factor in favor of the Niagara.

Q. And which would come next on that?

A. St. Clair.

Q. And the St. Lawrence last?

A. Yes.

Q. Now, let us take the range of lake stages covered by the observations.

A. The range of lake stages are 3.92 feet for the Niagara; 2.43 feet for the St. Lawrence, and 1.74 feet for the St. Clair.

Q. Now, other things being equal, and dealing with that as a separate factor, would the fact that as to one river the observations had been so conducted that a larger range of lake stage was covered have a tendency to give added weight to the deductions which were based upon those observations?

A. Considering all other things being equal, including the maximum range of variation of the lake surfaces, that is, that the rise and fall of all the lakes is the same, we would consider the observations the most reliable which covered the widest range.

Q. I am speaking of that as an independent—

A. I will not be sure we got that in, because it is not a fact at all. The ranges covered—the proportion of the total variation of lake surfaces covered were greater on the St. Clair than on either of the other rivers, if I remember correctly.

Q. How do you make that?

A. Would it be agreeable to you to pass that question and go to the following one, and let me answer that a little later, because I find the computation is not here. The result is here, but on what I base it, at the present moment I am unable to recall.

Q. The ratio of fluctuations between Lake Huron and Lake Erie, I understood you to say a little while ago, was 70 per cent.?

A. That is the ratio of the average annual fluctuation. The maximum fluctuations, however, of Lake Erie at Buffalo are between two and three times as great as those of Huron, according to the best information that I have.

Q. You mean monthly means?

A. No, I mean daily.

Q. Daily means? And you mean including the effect of storms?

A. Yes, they affect the gage to which reference is made. Therefore, I would include them.

Q. Well, is it not your opinion that so far as the questions which we have under consideration here are concerned, it is the monthly mean level which is the correct criterion?

A. For the purpose of this comparison, I think I would make it with the monthly mean.

Q. Well, then, I don't exactly understand your last statement in its relation to what you have said before, Mr. Williams, about these variations. We are discussing these different elements of precision?

A. Yes.

Q. And I have taken them up in order, and one of them is the range of lake stages which were covered by the observations.

A. I would like to make a statement here, that I will answer a general question, if agreeable to you now, just because I am not prepared to answer this specific question.

I arrived at these percentages by reference to some value of lake fluctuation. What it is, I have not in mind now; and if I am in error, of course, I will be glad to acknowledge it. I want to find what I thought I had. The question, I would answer frankly—I will answer them all frankly as far as that goes—what I mean is, I will answer this general question: Of a series of gagings, that gaging which covers the largest proportion of the range of stage to which the discharge equation is to be applied would be considered the more probably accurate or reliable gaging.

Q. And you take the monthly mean as the criterion?

A. You should take whatever you are going to apply the gaging to as your criterion. For your general readings, you are applying to monthly means. That is as fine, I think, as anyone has attempted to go.

Q. And so far as the lowering of the lake and the diversion is concerned, what would you take, monthly mean?

A. You mean the effect of the diversion?

Q. Yes.

A. Well, the smallest unit in which the opinion is taken has been monthly mean. It has been applied to ten-year means, and monthly means, and since the increment is assumed to be derived from a straight line curve—or as long as it is assumed that the increment is constant for all elevations of the lake, it makes no difference whether you take it by the year or the month.

Q. Isn't it a fact, so far as the Niagara observations are

concerned, which have been under consideration in this case, that if you take the monthly means you have observations which are lower than the lowest monthly observations, and observations which are higher than the highest, so that the range of observations covers the whole range of lake stage?

A. That is true as to Niagara. It is also true as to the St. Clair, confining the period of investigation to that since 1890, before which time it is our belief that the gagings do not in anywise apply.

Q. Having in mind that one factor, you would expect results from the Niagara observations which would have a higher degree of credibility than on either one of the other rivers, would you not, just from that element alone?

A. Just wait a moment there, I was just thinking whether—

Q. But more particularly with regard to the increment?

A. Assuming all other conditions equal, the longer range in elevation covered by the observations would lead to a more accurate determination of the increment.

Q. For the obvious reason, if you plot the observations, the longer the line you have, the more accurate the trend.

A. Exactly. The increment is that factor in the equation which determines the inclination of the line, and that can be more accurately determined the longer the line is.

Q. Let us take as a factor in determining the credibility of these different pieces of work the number of observations and what you find as to them?

A. The St. Clair ranks first, Niagara second and the St. Lawrence third.

Q. Let us take now, the fifth to be taken into consideration in reaching a conclusion as to the credibility of these different pieces of work by the Government engineers, the duplication of sections and the opportunity for a corroborative check, what do you find as to the three rivers?

A. I would consider, as far as duplication went, the Niagara has the advantage. The St. Clair, of course, ranks next.

Mr. Adcock: When you say duplication, what do you mean by that?

A. That they had two sections—well, now, just wait a minute on that answer; I think that is pretty nearly an open question between the St. Clair and the Niagara. On the Niagara the two sections were quite close together, whereas on the St. Clair they were further apart. Considering the relative number of observations, I think I will give the Niagara a slight advantage on that.

Q. Referring again to the question as to the number of

observations, I will ask you to refer to the charts which were introduced in evidence by the Government and state what you find there indicated as to observations in the years 1907 and 1908?

A. Chart Complainant's Exhibit 3 states that the number of discharge measurements from 1898 to 1900 was 101; from 1907 to 1908 was 118, making a total of 219.

Mr. Adcock: That is on the International Bridge Section?

A. Bridge Section Niagara River.

Mr. Wilkerson: Let us take the sixth fact and consider it. Let us take the different conditions as to velocity and so forth in the various sections of the same rivers which were gaged. Take first the St. Clair now.

A. The velocities at the Dry Dock Section of the St. Clair were lower on the average than they were at Niagara, and I think lower than at the St. Lawrence.

Q. I want to first compare the conditions at the different cross sections of the same river. Take the cross sections of the St. Clair which were measured, what were the sections?

A. The section at the Dry Dock was below Port Huron, below the mouth of Black River, about five miles from the foot of the lake; and the Gorge Section, which is within about a mile of the foot of the lake.

Q. As to the velocity, the Gorge Section was about twice the velocity of the Dry Dock Section?

A. I do not recall those things.

Q. I want to get the substance, of course.

A. I should say that statement was substantially correct, without looking at the actual figure.

Q. Then take the sections in the several channels at the Delta, they have a smaller velocity than the Dry Dock Section?

A. Generally.

Q. Do you know how much smaller velocity the sections in those channels have than the Dry Dock Section, roundly speaking?

A. I would prefer not to answer those questions without an opportunity to make the necessary computations because I see that the—

Q. It is a fact that at the Gorge Section the velocity is about twice as much as the Dry Dock?

A. I am not prepared to say so at the present moment. I was under the impression it was materially greater.

Q. And that the Dry Dock was materially greater than the Delta?

A. No, I was not prepared to say that, but I would rather expect that.

Q. Notwithstanding the difference in those conditions of velocity, and other conditions which have been referred to already by you in your testimony how do those three sections on the St. Clair River check with each other?

A. The Gorge and the Dry Dock check very well. I have made no comparisons of the others.

Q. What do you mean by observations taken at two different sections checking?

A. Well, when referred to the same lake stages, lake elevations, they should give similar discharges.

Q. I will ask you to refer to the reports relating to these observations and ask you to give us the facts with reference to the velocities at the Delta Section.

A. In answering that question, I wish to say that I have as yet made no study of these discharges here, except as indicating the relative magnitude of discharges in the different Delta Sections. And to answer that question, I would think would take some little time.

Q. I will ask you, Mr. Williams, for the definite facts as to this, to look it up when we take an adjournment to-day, so that it can be put in the record to-morrow morning.

A. What is it you want?

Q. The facts with reference to the velocities in the channels of the Delta Section as compared with the velocities in the Dry Dock Section?

A. I do not find in the report as yet that those statements are given anywhere. It will involve—

Q. I pass that, and now I say, assuming that there is a material difference in the velocities between the Delta Section and the Dry Dock Section, and that the Gorge Section has a velocity about twice that of the Dry Dock Section; assuming that those sections check substantially with each other, what weight in your opinion is that fact entitled to in determining the degree of credibility which is to be given to those measurements?

Mr. Adcock: When you say "check," you mean comparing the observation with reference to similar observations?

Mr. Wilkerson: By "check,"I will accept the definition which he gave of "check."

A. The coincidence in magnitude of discharge measured at different points under different conditions of section would indicate the similarity in degree of accuracy of the work involved. It would indicate that aside from such sources of

inaccuracy as were present in all gagings—in all the measurements considered, that the observations were entitled to a degree of credibility dependent upon the coincidence of the measurements.

Q. So that the more accurately they checked, the higher the degree of credibility to be accorded to the work, even though the velocities at these different sections were different, as assumed in the question that has been put to you?

A. That is correct, bearing in mind always that those coincidences can have no effect upon errors which are continuing through all the observations, if there be any such.

Q. Wouldn't the fact that these three sections checked substantially in the way assumed in the question eliminate the item of any difference in velocity as one of the—.

A. You mean difference in velocity at the sections?

Q. Yes; as one of the sources of inaccuracy, in connection with the work?

A. Yes. I do not recognize the differences in velocity as being a source of inaccuracy, however, up to date.

Q. Now, then, I wish you would explain to us a little more in detail just what you mean by one of these sections checking with another, and try to put it in just as concise form as you can, what that checking of the two sections means to an engineer as to the kind of work which has been done in the measuring of the different cross sections?

A. If when applied to some reference condition, due consideration being made for the time element involved, if the measurements at consecutive sections on a stream agree, it would give to any engineer great confidence in the accuracy of those measurements, subject only to such conditions of error as errors of rating and errors of general method, which would be applicable alike to all points in observation?

Q. What were the sections on the St. Lawrence which have been measured?

A. The only one that has been considered in my testimony is the section at Point Three Points, which is that covered by—being Table Number I, summary of discharges, Three Point Section, St. Lawrence River, F. C. Shenehon, Assistant Engineer, May, 1906, and including 96 observations.

Q. There was a check, was there not, at Little Church Bay?

A. As to that I have no information, as no records of gagings at that section have come into my hands, as being exhibits in this case.

Q. Do you know as a matter of fact whether on the St.

Lawrence River, the measurements were checked by a check section at Little Church Bay?

A. I do not.

Q. That that you last referred to was Williams' Exhibit 25, was it?

A. Williams' Exhibit 25.

Mr. Wilkerson: Do you remember now whether or not the Government's principal witness in presenting these tables upon which the Government relies stated that the observations in the St. Lawrence had been checked by a section in the way in which I have indicated?

A. I do not recall.

Q. But so far as you are concerned, you have made no analyses of the St. Lawrence observations?

A. Except as indicated in the table.

Q. Except as indicated in the table, and no analysis for the purpose of determining how accurately the observations there relied upon check with the section which was measured at Little Church Bay?

A. No.

Q. Referring to the Little Church Bay Section check, do you find now the portion of the record in which that matter is described?

A. Little Church Bay is not mentioned. A section at Nevins Bay, Nevins Point, is mentioned, and the statement—

Q. It appears that the correct name of that section is Nevins Point Section, and not Little Church Bay Section?

A. That is the name that was used by the complainant's witness. The statement is made: "The winter measurement checked the summer measurement within less than one per cent." And in answer to further questions: "They corroborated the sumer measurements, so far as volume is concerned. The range was not sufficient to determine anything regarding the increment."

Q. Now I direct your attention to the fact that it is there stated that there was slow velocity of one foot per second, and that the measurements check within less than 1 per cent. What does that indicate to you as an engineer as to the accuracy of that work?

A. That work was of the same high degree of accuracy in its performance, as the standard established by the work of the United States Lake Survey would lead one to expect.

Q. What was the mean velocity at the Three Point Section? And I refer you in that connection to the report of the Chief of Engineers for the year 1902, page 2803?

A. According to the testimony of the complainant's witness Shenehon, page 498 of the continuously paged record, the current had a mean speed of about one foot per second on this section, referring to Nevins Point.

Q. I am referring to the Three Point Section, and I direct your attention to page 2803 of the report of the Chief of Engineers for the year 1902.

A. According to the testimony of complainant's witness Shenehon, on page 579 of the continuously paged record, in answer to the question, "What was the cross sectional area of the St. Lawrence River at the point where discharge measurements were taken?

A. 51,000 square feet, roundly."

Now, the discharge of the St. Lawrence was approximately 225,000 cubic feet per second, which would give a mean velocity of about 4.4 feet.

Q. Having in mind the fact that the measurement of one of these sections corroborates in the way indicated the measurement of the other, and having in mind the wide divergence of the velocity of the river at the two sections which were measured, what does that indicate to you as an engineer as to the degree of credibility which is to be given to the measurements made by the engineers based upon those observations?

A. Subject always to those sources of error, which would be inherent in both measurements, it indicates exceptionally good work.

Q. Of which the difference of velocity does not appear to be one of the factors which would cause doubt or uncertainty as to the result of the work?

A. Within those ranges, no.

Q. What were the two sections of the Niagara River which were measured?

A. The International Bridge Section and the Open Section so called.

Q. And what were the different conditions as to velocity in the two sections which were there measured?

A. The cross section at the International Bridge is stated by complainant's witness Shenehon, on page 580, to have been 39,000 square feet, and that at the open section 42,000. The discharge reported is about 190,000 cubic feet per second. This would indicate a velocity, an average velocity of about 4.9 feet for the International Bridge Section and about 4.5 feet for the Open Section.

For a discharge of 200,000 cubic feet per second, the aver-

age velocity at the International Bridge Section would be about 5.12, and at the open section about 4.75.

Q. Well now those sections checked with each other, did they?

A. On the average discharge from 1900 to 1907, the equations derived by the complainant from the gagings at these two sections, show a difference of about 2,700 cubic feet per second or a little over ¼ of 10,000 cubic feet per second.

Q. Expressed however in per cent. of the volume of discharge, within what per cent. would it be?

A. Slightly over one per cent.

Q. They check within slightly over one per cent.?

A. Yes, about 1¼.

Q. Now having in mind the facts to which you have heretofore referred in your testimony with reference to the physical conditions at the place of each of these sections, and the fact one was an open section and the other was a bridge section, and the other physical conditions, what does the fact as to the checking of these sections indicate to an engineer, as to the degree of credibility to be given to the work of the Government Engineers in this respect?

A. That so far as the performance of those labors which it was possible for the individual to perform, the work has been exceptionally well done; that whatever errors are present are inherent in both series of observations to practically the same extent.

Q. I wish to direct your attention to another element as affecting the accuracy of the work done in the measurement of these rivers, namely passing boats. That I think you have mentioned several times in your testimony as a disturbing factor, particularly in connection with the prosecution of some work done on the St. Marys River. What were the conditions so far as passing boats were concerned in the three rivers, the St. Clair, the Niagara and the St. Lawrence when they were measured, how did they compare?

A. The effect of passing boats in both the Niagara and the St. Lawrence would have been relatively insignificant. They would I think have been of importance on the St. Clair.

Q. In that respect then there were elements of advantage when the Niagara and St. Lawrence were measured, which were not present when the St. Clair was measured?

A. Yes, sir.

Q. Let us take the situation which was presented to the engineers in measuring the St. Clair River. Is there anything in the presence of Lake St. Clair and in connection with

the effect of Lake St. Clair upon Lake Huron—I mean anything in the presence of Lake St. Clair in the place it is, which injected into that situation an element of complexity which in your opinion was not present in the case of the measurement of either the Niagara or the St. Lawrence?

A. The presence of Lake St. Clair would have only a very limited, if any influence upon the measurement of the quantity of water passing. It has an important influence upon the connection of that quantity of water with the stage of lake to which it is related.

Q. That is the increment?

A. No, that is not the increment. That is with the establishment of the quantity of water which will be delivered for any given stage of lake.

Q. Does it not make the derivation of the increment of the St. Clair River a more difficult problem than it would otherwise be?

A. Than of the other two?

Q. Yes.

A. It does.

Q. It is a harder problem to derive the increment for the St. Clair, other things being equal, by reason of the presence of Lake St. Clair, than it would be to derive the increment of either the Niagara or St. Lawrence. That is an element of complexity that is not present in the other two problems?

A. It is the most serious element of complexity that is encountered in the entire investigation.

Q. Now were there any water gage troubles encountered in the measurement of the St. Clair which caused any difficulty in the measurement of that river?

A. Yes, there were.

Q. What were they?

A. The gagings originally were attempted to be referred to a gage at Fort Gratiot Light. This gage became choked up, the pipe connecting to the gage became choked up with sand, and it was necessary to transfer the reference observations to Harbor Beach, by means of a series of simultaneous observations upon the gage at Fort Gratiot and at Harbor Beach. The gage in Lake St. Clair appears to be of very questionable reliability on account of the inattention, apparently, of the gage reader there.

Q. So there was an element of uncertainty in the St. Clair problem which was not encountered in the case of either Niagara or St. Lawrence?

A. There is an element of uncertainty which was encountered in attempting to connect the gagings of St. Clair River to the lake elevations corresponding to them. Whether there were similar difficulties on the Niagara or the St. Lawrence, I am not informed. It is my impression that there were certain difficulties with the Buffalo gage.

Q. You say that is your—

A. That is an impression that I have. I will say that there has been certain difficulties with the Buffalo gage. Whether they were present during the observations or not, I am not certain, but I noticed that there were some changes of gages at that time, as shown by the gage records.

Q. So far as this Buffalo gage is concerned, you are not to be understood as indicating that you have any specific information of trouble of the kind mentioned by you, are you?

A. No, I simply say that I have seen references to trouble with the Buffalo gage at various times. Whether there was any trouble during these observations, I don't know, and I would anticipate that with the experience that had been had before, that if there were any such that they would have been looking out for such trouble and probably pretty promptly eliminated, if it had been discovered.

Q. That is by that you mean they lose a record of a day occasionally?

A. Well I do not recall specifically what the difficulty was with that gage, but I have known of criticisms of it from time to time.

Q. It was not a very serious difficulty, was it?

A. I don't know; it might or might not have been depending on its location. I could conceive that there might be some question as to whether the gage at all times represented the true surface elevation of Lake Erie in that location. That would, however, have no bearing upon the accuracy of the measurement of the quantity of water passing. Don't let us get confused on that point, that any criticism of a reference gage away from the section would have no bearing whatever on the quantity of water passing at the time the measurement was made.

Q. But it would have a bearing in deducing the law of discharge of the river?

A. It would have a very important bearing on that.

Q. Now I understand you to say that it has been your view in the study which you have made of these observations that the reason for rejecting the law of discharge which flows from

the observations as a mathematical proposition is that Lake Erie at Buffalo is so capricious that it does not remain steady long enough to secure good results in gaging. I understand that to be true?

A. That is an element and an important element.

Q. Well, is it the most important?

A. If you change the word "capricious" to "unstable", I think it would come more clearly conveying the meaning.

Q. That is to say your reason for rejecting the conclusions which necessarily flow from the Niagara observations is that in your view Lake Erie at Buffalo is unstable.

A. That is one reason.

Q. I gathered from your analysis of these figures that that was your prinicpal reason?

A. No, I don't think it is. I think there are other reasons that are as potent.

Q. Well, that is a reason?

A. That is a reason and a strong reason.

Q. You give great weight to that?

A. I do.

Q. In arriving at the conclusion that the same use cannot be made of the observations of the Niagara River as are made of those of the St. Clair and the St. Lawrence?

A. (No response.)

Q. How did you get that impression that Lake Erie at Buffalo was so unstable that it did not remain steady long enough to secure good results in gaging?

A. From its performances at Buffalo, and from its performances at the other end of the lake at Amherstburg. The rise at Buffalo must be followed by a fall at Amherstburg, when the gage at Cleveland remains at the same elevation, and the changes of level at Amherstburg have been sudden and unexpected many times.

Q. Is it your opinion that the elevations of Lake Erie at the head of the Niagara River governed the outflow of that river?

A. Not entirely.

Q. Does it have anything to do with it?

A. Considerable.

Q. Is it a principle factor in determining the outflow of the river?

A. Ordinarily.

Q. By ordinarily you mean what?

A. I mean under ordinary circumstances.

Q. Under ordinary circumstances. That is to say any other circumstance is an exceptional circumstance?

A. Yes.

Q. What are the other circumstances when the volume of water going through the Niagara River is not controlled by the elevation of Lake Erie?

A. By the elevations of Lake Erie where?

Q. At the head of the river.

A. In cases of variable barometric pressure along between the two ends of the lake.

Q. Which lake is this, Lake Erie?

A. Between the two ends of Lake Erie; that is, I could conceive of a barometric pressure at the lower end of the lake, with a lighter one at the upper end, which would cause a tilting of the water in Lake Erie, independent of wind effects, in which the discharge would be larger for the lowered elevation at the east end of the lake than would normally occur there.

Q. Is this purely theoretical, or is that based upon some study which you have made of that subject?

A. Well, it is based upon the well known laws of physics.

Q. Why is that true, in your opinion?

A. Because the pressure producing the discharge is not only the pressure of the weight of the water itself, but pressure of the superincumbent air, and if the pressure of the air changes and the pressure of the water did not change, the effect would be to force out more water. Now if the pressure of the air changes, to maintain a uniform pressure, the pressure of the water must decrease, in other words the water must drop, and consequently measuring your forces producing discharge by the elevation of the surface of the water would cause an apparently lower discharge than might actually be taking place, and conversely.

Q. Is it not a fact that the air column at the Buffalo gage, or at the head of the Niagara River is balanced by the air column in the river two miles below, as at Austin street, and that it is therefore eliminated in causation of flow?

A. That is not necessarily so. Observations which I have made barometrically have indicated to me that where you come in from a broad open reach into a constricted area, particularly such as exists in the neighborhood of a large city where buildings obstruct the free passage of air, that there may be quite sudden and appreciable barometric changes or differences of barometric pressure at the same time, and it is entirely possible that the barometric pressure at Austin street, or even at the International Bridge, might be appreciably different from that at the foot of Lake Erie.

Q. What is your view as to the limit of the variation produced by this cause, which you have just specified?

A. Why it might easily amount to as much as .05 of a foot.

Q. .05 of a foot?

A. Yes.

Q. What percentage of the volume of discharge would that be?

A. About ¾ of one per cent.

Q. Now that is a factor, if I understand the situation that is just as likely to be on the one side as on the other, so that over a period of time there would be a tendency to balance, would there not?

A. Yes. It is not an important consideration, but when you ask the broad general question, I think that it points—

Q. I want some other factor you have in mind as indicating to you as an engineer that you cannot deal with these Niagara observations in the same way as engineers deal with the St. Clair and the St. Lawrence, besides this barometric pressure condition?

A. Well, the barometric pressure condition would apply to the other observations, to some extent at least.

Q. That is to both the St. Clair and the St. Lawrence?

A. Both the St. Clair and the St. Lawrence, probably less to the St. Lawrence than to the St. Clair.

Q. It would be a greater factor at St. Clair than Niagara, wouldn't it, on account of the greater distance between Lake Huron and Lake St. Clair?

A. I would be in doubt about that on account of the question of the elevation of the land and the height of buildings coming in. I think that it is the obstruction by elevations of free flow of the air back and forth that has considerable to do with these changes of barometric pressure that you get on occasions.

Q. You do not regard this as a particularly important factor, as distinguishing the Niagara from the St. Clair and the St. Lawrence?

A. Not at all.

Q. What influence on the discharge of the Niagara River does the elevation of the water at the west end of the lake have, that is to say at Amherstburg?

A. Not very much.

Q. Does it have any?

Mr. Adcock: You mean the elevation different from the elevation at the other end?

Mr. Wilkerson: With the lake tilted up.

A. When the lake is covered with ice, it might have an influence.

Q. We are speaking about the open season, aren't we in this case?

A. Oh, I didn't know that you were,

Q. Now as a matter of fact isn't it a statement of the fact, a statement of a correct fact to say that the flow through the Niagara River is governed by the elevation of the lake at the head of the river?

A. That is substantially accurate, and accurate enough for all practical purposes.

Q. Why did you put in the tables showing an increment derived from the mean of the observations taken at Amherstburg and Buffalo?

A. Because the elevations of Lake Erie upon which discharge is computed is referred to the mean elevation of the lake; that is in all the discussions of the effect of the increment, we have been dealing with the lowering of the lake as a whole, and the true elevation of Lake Erie cannot be represented by any single gage, but requires at least four. We have only three, Buffalo, Cleveland and Amherstburg. The mean elevation of the east and west ends of the lake is perhaps as near an average elevation of the lake as is a gage on the south side of it, and is certainly nearer to a mean elevation than a gage at one end.

Q. But in a series of observations taken over a number of days, the observations at Buffalo must control, do they not?

A. Yes, must control, except that that is not a sufficient control, for the reason that we should also know what the elevation of the lake is on the Canadian shore; that for an accurate comparison we should have the relation between the elevation of the lake at the Buffalo side and at the Canadian side, as there may be appreciable variations between the two sides.

Q. You mean for the control of a single observation, or are you considering water level?

A. I am considering connecting the discharge with the elevation of the lake, whether it be for a single observation, or a series.

Q. At Buffalo?

A. Buffalo or anywhere else; that an observation taken on one side of the lake is not a sufficient establishment of the elevation of the lake controlling discharge to lead to an accurate determination.

Mr. Adcock: Of the increment?

A. No, the relation between discharge and stage.

Mr. Wilkerson: Are you aware of the fact that under the supervision of the Deep Waterways Commission there was a gage maintained on the Canadian side as well as on the American side?

A. I recall that there were gages on the Canadian side of the river during some of the work of the Board of Engineers on Deep Waterways.

Q. And are you aware of the fact that they corresponded so accurately that as a result of the experiment, it led to the abandonment of one of them?

A. I am not aware of that fact. I am not surprised that it has been abandoned, but even with the experience that might have been gained in a short period of time such as that covered by the observations of the Board of Engineers on Deep Waterways, it does not seem to me to be conclusive.

Q. Have you ever examined the observations?

A. I have not.

Q. Made any study of them?

A. I have not, of the comparison of those two gages.

Q. Do you know the period over which they were taken?

A. I do not, but I know the period during which the Board of Engineers on Deep Waterways were in operation, approximately.

Adjourned to Tuesday July 22, 10 a. m.

Tuesday, July 22, 10 a. m.

GARDNER S. WILLIAMS, resumed the stand for further cross-examination by Mr. Wilkerson and testified as follows:

Q. We were speaking yesterday about the checking of different cross-sections of a river, and with reference to what is meant by the instability of a river. You expressed your opinion that the Niagara River was too unstable to be dealt with in the way in which engineers generally deal with rivers in this respect. Did you have in mind a statement appearing on page 284 of the report of the Board of Engineers on Deep Waterways, part 1? I direct your attention specifically to the page which I have indicated, and read the following:

"In connection with the direct observations made to determine the outlet from the lake at different stages, continuous

readings were made of the gages from which the slope of the foot of the lake and the river surface has been computed for the corresponding volume of discharge, which with the carefully measured cross-sections of the river shown on plate 8 y furnishes a check on the equation of discharge given above and shows a discrepancy of less than 3 per cent. for maximum volume of outflow used in this discussion"?

A. I am not aware that I expressed the opinion that the Niagara River itself was too unstable. I did express the opinion that the variation between Lake Erie and the Niagara River was too unstable, and I still maintain that conclusion.

Q. In your opinion, why is it that the relation of the discharge of the Niagara River and Lake Erie is such that the law of discharge cannot be derived?

A. The first reason is on account of the instability of Lake Erie. In order to create the flow through the Niagara River that corresponds to any stage or elevation of the surface of Lake Erie, time must be given for the river to be affected clear to the Falls.

Lake Erie does not remain in one position long enough for this effect to take place, or if it does it is only on very rare occasions.

A second reason is that when Lake Erie rises at Buffalo it almost—when it rises as the effect of winds on account of which it is vibrating daily almost, as the plottings in exhibit, William's Exhibit 35, chart 4, will show, wherein are plotted the gage readings at Buffalo daily, as derived from William's Exhibit 29, there is presented graphically the fluctuations of the surface of the lake at Buffalo. Now when the water rises at Buffalo and lowers at Amherstburg, that rise at Buffalo is caused by a flow towards Buffalo along the surface of the lake created by the action of the wind. At the same time there is a counter flow from Buffalo towards Amherstburg through the lower portions of the water; during the time that the lake is rising, the flow towards Buffalo necessarily is greater than the flow back towards Amherstburg, but at the moment that the lake becomes stable in any position the flows in the two directions, are for the time being, alike. As the lake at Buffalo begins to fall, the flow towards Amherstburg increases.

Now, it does not take an elaborate computation to show that the velocity of flow towards Amherstburg to be observed at such times and with such differences of elevation, as have frequently occurred between Buffalo and Amherstburg; the flow away from the mouth of the Niagara River is greater than the

flow into it. At those times the discharge—I should say the velocity of flow away from the mouth of the Niagara River is greater than the velocity into it. At those times the discharge for the Niagara River, while corresponding to the high stage of the lake, will necessarily be less than they would be were the lake at that elevation throughout its entire area.

Consequently, a considerable proportion of the measurements of discharge of the Niagara River at the higher stages give a discharge lower than those which naturally belong to the elevation of the lake to which they are alleged to correspond. This is outside of the fact that the discharge of the river does not come to that corresponding to the elevation of the lake for some considerable time after the lake has risen to the point, as it is necessary to fill a prism extending from the Falls to the entrance to the lake with water, the base or upper end of which is the change of elevation of Lake Erie; the lower end is zero and the area is the area of the surface of the river between the outlet of Lake Erie and Niagara Falls before the conditions of flow corresponding to that elevation of the lake are established.

Q. By that you mean that a velocity of approach enters in the movement of Lake Erie towards or from the river?

A. A velocity both of approach and of departure.

Q. In your opinion what is the measure of that velocity?

A. The measure of that velocity would be the volume of water which changes ends of the lake and the space through which it has to pass in that motion.

Q. What in your opinion is the velocity, say within a mile of the head of the river?

A. Within a mile of the head of the river, that is a matter of computation. It would be the volume of water which passes the section a mile from the river divided by the area through which it passes.

Q. Have you any opinion as to how much it would be?

A. It will vary greatly because sometimes the differences of elevation between Amherstburg and Buffalo are zero, frequently they are .6 of a foot, not for long periods; not infrequently they are more than a foot. On occasions during which observations were made, they have been something over three feet; and there are records, I am informed, of a difference of elevation between Buffalo and Amherstburg approaching 12 feet.

Q. That is sometimes one is higher and sometimes the other is higher?

A. Yes.

Q. Those are things that in the long run, one practically neutralizes the other?

A. That is correct. If you should take observations every day for a long period of time and refer them to the Cleveland gage and the observations were accurate, it would be possible to get an increment of Lake Erie that would be applicable in this case; but it is not possible by a reference to the Buffalo gage unless the observations should extend over a very much longer period of time.

Q. With Amherstburg one foot below Buffalo, in your opinion what volume of discharge would be added to the Niagara River?

A. That being the stable condition? That being the condition, having arrived at that condition you mean?

Q. One of these derivation conditions?

A. Lake rising or lake falling?

Q. Would it make any difference? Give both the rise and fall.

A. It would make a difference; if it is falling the tendency would be to decrease the discharge. If it is rising the tendency would be to increase it to a less extent.

Q. Well, take the case where the rise at Buffalo was within the last two hours preceding the taking of the observation.

A. A rise of a foot at Buffalo and a fall of a foot at Amherstburg?

Q. Where Amherstburg is a foot below Buffalo?

A. Where Amherstburg is a foot below? I should have to have some cross sections of the lake, in order to make that computation; but I wish to assure you that it is a figure well worth consideration, in dealing with this problem.

Q. Have you made any study of the Niagara observations for the purpose of determining whether the effect of a rising stage is shown in the discharge measurement?

A. I have not, any very extensive one.

Q. And from such examination as you did make, what was the conclusion at which you arrived?

A. I arrived at no conclusion from that examination, except that it is probable that the measurements are too inaccurate to represent these conditions.

Q. Did you not make any attempt to find that in the observations?

A. I have not, specifically.

Q. Take these observations during the two periods which are under consideration, 1899 to 1900 and 1907 to 1908, as I

understand it, how many times does it appear from those observations that there was a rise of as much as a foot at Buffalo within two hours?

A. As far as I recall, I have seen no data which would give that information.

Q. I direct your attention to hourly water levels as recorded by the self-registering gage at the United States Lake Survey, Buffalo, New York, during the months of June, July and August, 1908. I wish you would take those tables and state for each day what the variation in level is, and how much the variation for each day is from the mean level for the particular day, as indicated on the table?

A. I do not see that that information is in the tables here in such form as to be gotten readily. It will take some time to get what you want, as it involves both a searching through the columns here, if I understand the table, of 24 readings each day, and a subtraction from the mean; and it is a thing that any clerk can do. I have no reason to question the record here, or criticise it.

Q. I show you a document in three parts, consisting of three sheets, being marked table XLVII, 1, 2, and 3 respectively. They purport to be certain figures of the United States Lake Survey, Preservation of Niagara Falls, Elevation of Lake Erie, derived from discharge of Niagara River, International Bridge, Buffalo, New York, for the years 1907 and 1908, during the months of October and November, 1907, and June, July and August, 1908; and I ask you to state what appears on this table with reference to the change of lake level during the measurements; and in connection with the question, I ask the Commissioner to mark this Williams' Exhibit Cross Examination Number One; the same being the document referred to on page 473 of the record as one of the tables furnished to the counsel for the defendant.

Mr. Adcock: Counsel for the defendant state that they have no record or recollection of having or receiving the table.

Mr. Wilkerson: There is also a reference to this table in the plate which was introduced in evidence by the Complainant, based upon these Niagara River observations.

Mr. Adcock: I do not believe that is shown on the plate introduced in evidence. That has a reference to the table, but there is a statement that there were observations made in 1907 and 1908 on that plate referred to.

The Witness: You want an answer so this may be put in the record?

Mr. Wilkerson: Yes.

The Witness: Columns 5 and 6 of Williams Exhibit Cross Examination Number 1, purport to show the change of lake level during measurement for the several measurements which are identified by date in column number 2 and by number in column number 1, being measurements of the discharge of Lake Erie taken during the years 1907 and 1908.

Column 5 purports to give the rise in feet of lake level during the measurement and column number 6 purports to give the fall in feet during the time of measurement.

Mr. Wilkerson: I think you might as well incorporate this whole table in the record at this point, so there will be no misunderstanding about it.

						Means						572.586		

Mr. Wilkerson: Q. The figures to which attention has just been directed appear on pages 46, 47 and 48 of the document entitled "Preservation of Niagara Falls."

A. They do, but I am informed that the copy in the report "Preservation of Niagara Falls" has not been checked by the author of the table, and two typographical errors have been discovered in it up to the present time.

Q. What were they?

A. Errors as to the year in which the gagings at the bottom of page 46 and the top of page 47—

Q. That is to say observation numbered 41?

A. 41 was taken in 1908.

Q. And 46 was taken in 1907?

A. No, 46 was taken in 1908 also. The report shows all the observations that have been taken in 1907, whereas the major part of them were taken in 1908.

Mr. Adcock: Q. And I understand those inaccuracies were discovered by simply a casual reading of the exhibit, of the record?

A. They were called to my attention a moment ago by the principal witness for the Government.

Mr. Wilkerson: Q. How much time does it take ordinarily to make one of these observations?

A. I do not recall that that time has been specifically stated in any of the testimony regarding the Niagara River. Do you remember whether you stated it, Mr. Shenehon?

Mr. Shenehon: I do not remember whether I stated it. I know about the time.

The Witness: What I asked was whether there was a statement of it. My impression is about two hours.

Mr. Shenehon: That is right.

Mr. Wilkerson: Your understanding is that it takes about two hours to make one of the discharge measurements?

A. My understanding is that it takes about two hours to make one of the discharge measurements, according to the methods that have been used.

Q. Now this table number 47 to which I have directed your attention, identified as Exhibit 1, Cross Examination of Williams, shows the change of lake level during the time of measurement?

A. Yes, it purports to.

Q. And the same is true of Table Number 1, summary of discharges of International Bridge Section of the Niagara River, the observations were made in 1898 and 1899?

A. It was regarding that latter table that I was testifying, but the statement is true in regard to both.

Let me make a suggestion that may simplify reference to these exhibits, unless you specially desire to have that exhibit identified, that is to have it as number 1, why not let it appear consecutively in my testimony, and you can enter a note that the exhibit is introduced in cross-examination, beginning with number so and so.

Mr. Wilkerson: We will have to get the matter of numbering these exhibits straightened out. It appears to be an exhibit which apparently was produced at the taking of the Government's direct testimony, and it was stated that it was part of the information which was furnished to the defendant; so properly it goes into the record as one of our exhibits.

Now, for convenience, in connection with your testimony, I have referred to it as Exhibit number 1 in your cross-examination, but we will have to give it a number when we come to print this record; it will have to be numbered as a Government exhibit. We will have to go through the exhibits and arrange them in that way because it is really one of our exhibits.

Mr. Adcock: It is absolutely confusing, the way those exhibits are in there; tables and so forth all mixed up, A, B, C and so on, and there is no way of arranging them.

The Witness: They were only marked for identification. There were I think seven exhibits put in by the Government in their direct testimony if I remember right.

Mr. Wilkerson: Q. Referring to these Niagara River observations, and to the column which indicates the change of the lake during the time of making the observation; let us take the first observation that appears in the 1898 observations: Measurement number 5 September 10, 1898, shows that during the time of the measurement the lake rose .02 of a foot, and fell a little more than .2 of a foot?

A. That is correct.

Q. And taking number 6 observation made on the 13th of September, 1898, that shows that during the time of the measurement there was a rise of .06 of a foot and a fall of .22 of a foot?

A. That is corerct.

Q. Take observation number 7, the same being made on the 13th day of September, 1898. That shows no rise, and a fall of .21 of a foot?

A. That according to this record was on the 13th.

Q. The 13th of September, 1898?

A. No rise, and a fall of .21.

Q. And observation number 8 for September 15, 1898, shows a rise of .07 and a fall of .11?

A. Correct.

Q. And number 9 for September 15, 1898, shows a rise of .44 and a fall of .02?

A. Correct.

Q. And number 10 for the 17th of September, 1898, shows a rise of .06 and a fall of .15. Number 11 for September 17, a rise of .18 and a fall of .06. Number 12 for September 20th, shows a rise of .13 and a fall of .20. Number 13 for September 20th, 1898, shows a rise of .15 and a fall of .06. Number 14 for September 22, shows a rise of .02 and a fall of .12?

A. You said the 15th or 14th?

Q. 15th.

A. Number 15 shows a rise of .25 and a fall of .07 according to this.

Q. Number 14 is the last I read.

A. I misunderstood. I thought you said 15, and that is what I caught here.

Q. Considering this table as a whole, Mr. Williams, what in your opinion does it indicate to an engineer as to the stability of the lake during the larger portion of the periods covered by these observations?

A. Understanding by "periods covered by these observations" to mean the time elapsing between the moment of beginning and the moment of closing a single observation of discharge, it shows that the lake was reasonably stationary at that time.

Q. Would you say the same thing with reference to the observations which are set down in what has been called table XLVII, the same being the observation on "Preservation of Niagara Falls" for the years 1907 and 1908?

A. Without a minute examination of the table I can't say that that is so. There should be an exception made in regard to certain observations in both tables, where the rise and fall becomes an appreciable factor, or at least is larger than I would consider represented stable conditions; as for example observation 113 of William's Exhibit 1 on Cross Examination Number 1, where there is a rise of .25 and a fall of .8. That is followed by one the same day, wherein the rise was .3 and the fall was .47.

Also a few of those observations in William's Exhibit 24,

as notably observation 58 on November 9, which shows a rise of .45 and a fall of .27; observation 62 on the 10th shows a rise of .67 and a fall of .03.

These are rather exceptional and considering the series as a whole I would say that the stage of the lake, the elevation of the lake was reasonably constant during the observations of discharge.

Mr. Adcock: You mean during the time—

A. During the actual time the observation of discharge was being made.

Mr. Wilkerson: Q. Referring specifically to observation number 113 in table number XLVII William's Exhibit on Cross Examination number 1, and directing your attention to the last two columns of the table relating to that observation, I will ask you whether it is not a fact that observation appears to be consistent with the other observations appearing in the table?

A. Let me have that exhibit will you please until I see if this is an actual transcript (examining same).

Q. (Question read.) A. So far as the comparison shows between a computed elevation of the lake based upon a discharge equation and the observed elevation of the lake, I see nothing to particularly mark this observation from the other. In fact the coincidence of the two quantities, the computed elevation and the actual elevation is closer than in several others of the series.

Q. You referred to one or two others, which you refer to as being rather exceptional. What did the table show with reference to those, as to their being consistent with the other observations?

A. To answer your question specifically, the other observation referred to in this table was number 114. I do not find that similar information is given in regard to the previous measurements, but so far as observation number 114 goes, the coincidence is even closer, very much closer, than in observation 113. I would say however that I do not wish my answer to the previous question to be misunderstood. The question that was asked me was whether those elevations given in this table indicated a stability of the lake surface during the measurements. Now, to my mind, the instability of the lake surface during the particular hours of the measurement can be quite readily corrected, the stability or instability can be quite readily taken care of in the reduction of the observations, and I assume it has been.

Q. I call your attention to observations Nos. 57, 58, 60 and 61, and ask you to state what appears as to the change of lake during the measurements and also what appears as to the effect which the changing lake stage appears to have had upon the volume of discharge.

A. Observation 57 shows a rise of nothing during the observation; a fall of .46 of a foot.

Observation 58 shows a rise of .45 during the observation and a fall of .27. The elevation of the lake in observation 58 was .03 of a foot higher than in observation 57. The discharge was increased 1,600 cubic feet, which would indicate an increment of 53,000.

That elevation for observation 57 is given here as 570.11 and for 58 as 570.14. The discharge for observation 57 is given as 155,600 cubic feet per second, and the discharge for observation 58 is given at 157,200 cubic feet per second.

Mr. Adcock: Q. The difference is how much?

A. The difference I make 1,600 cubic feet per second. Dividing that by .03 seems to give 53,000 as the increment.

Mr. Wilkerson: Q. Is it your opinion as an engineer that increments can be derived in that way?

A. That, if the gaugings were accurate, that is the increment indicated by those two discharges. If the measurements were accurate, that is the increment of those two conditions.

Q. Well, is it your opinion as an engineer that engineers would take the derived increment from two observations, where there was a difference of only .03 of a foot in the level?

A. If the errors of the observation are as stated by the principal witness for the complainant, namely, something like 1 per cent., an increment so derived ought not to be in error more than the 1 per cent.

Q. Referring to the column at the extreme right of the table, with reference to these observations, what is the discrepancy as indicated by the percentage there shown?

A. Well, I don't know what that percentage represents. They are, opposite observation 57, minus 0.9, and opposite observation 58, minus 0.2.

Q. Does that indicate to you as an engineer whether or not the rising or falling stage has an effect upon the volume of discharge; and if so, what?

A. That shows on the face of it that the larger discharge occurs on the rising stage.

Q. By what per cent.?

A. Well, that depends altogether upon what the correct value of the increment is, and without knowing that I can't say. In the increments the value which was assumed in the complainant's equation, it is about 100 per cent. It affects the increment to the extent of about 100 per cent.

Recess to 3 p. m.

After recess, 3 p. m.

GARDNER S. WILLIAMS resumed the stand for further cross-examination by Mr. Wilkerson and testified as follows:

Q. You have the three plates that were submitted to you this morning?

A. Yes.

Mr. Adcock: You mean the photographs?

Mr. Wilkerson: I will ask you now to refer to the three copies of hourly water levels as recorded at Buffalo, during the months of June, July and August, 1908, which for the purpose of this question I ask to have marked "Williams Cross-Examination Exhibit 2," the same being three sheets, and ask you to state what those observations show with reference to the variation of the water level of Lake Erie, say, the difference between the maximum and the minimum and the variation from the mean at Buffalo.

(Document referred to in the question was marked Williams Cross-Ex. 2.)

Mr. Austrian: Those computations, Mr. Williams, were made from Williams Cross-Ex. 2, were they not?

A. They were.

Q. And this document Cross-Exhibit 2, was handed to you for the first time this morning and those computations were made by your assistant during the noon recess?

A. They were.

Mr. Adcock: Have you given us the tables showing the hourly elevations during the remaining period of the gagings? I want the record to show that we make request on the complainant for those tables which we understand the complainant now has in his possession here at the hearing, and which we are advised by complainant's counsel supplement the three sheets known as Complainant's Exhibit 2, carrying readings for continuous periods much beyond those indicated on this exhibit. And the Government's counsel very courteously and kindly now hands to defendant's counsel the documents now called for.

Mr. Wilkerson: Just state, Mr. Shenehon, which ones of the tables were produced.

Mr. Shenehon: Photographs of the actual record of the United States Lake Survey for the Buffalo gage for the month of June, 1899, July, August, September, October, November, December of 1899, May, 1900 and June 1900.

Mr. Adcock: What are there left there?

A. July, 1900, October and November, 1907.

Mr. Shenehon: I haven't those.

Mr. Adcock: That is all you have at present, as I understand it.

Mr. Shenehon: Yes.

Mr. Adcock: Then we make a request for the similar tables covering the months which are not included in these tables.

Mr. Shenehon: I have some more: There is July, 1900, and May, 1899, October, 1907, and November, 1907. That is all.

Mr. Adcock: What months are not there?

A. We are then short July, August, September and October, 1898, January, February and March, 1899.

Mr. Shenehon: There are not any sheets of this kind for 1898. The gage was established February, 1899.

The Witness: Then there are similar records for February and March, 1899, which have not been furnished. Is that right, Mr. Shenehon?

Mr. Shenehon: We feel that February and March do not

enter into any gagings we are displaying in this case. That is open season flow. Of course there are gage records consecutive on that gage from the year 1900 to the present time, and still going on.

The Witness: Then the statement as I understand it is that this gage was established in February.

Mr. Shenehon: 1900.

The Witness: In 1899, wasn't it?

Mr. Shenehon: Yes, 1899, that is right.

The Witness: February, 1899, and there are no records of recording gage prior to that time.

Mr. Shenehon: That is my recollection.

The Witness: All right.

Mr. Wilkerson: As to the sheets which were submitted to you this morning, the same being three sheets marked Williams Cross-Examination Number 2, have you familiarized yourself with and given consideration to the facts relating to the subject about which inquiry was made this morning?

A. I have forgotten just what the inquiry was. If you will, inform me.

Q. The inquiry related to the range?

A. To what they indicated?

Q. The range of variation from day to day as shown by those sheets.

A. Do you wish me to enumerate the particulars, or give a summary?

Q. The figures of course now appear in the record?

A. Yes.

Q. I merely want to know whether you, the witness, have personally examined the results of that compilation, and have familiarized yourself with the facts shown?

A. I have to a moderate degree, yes.

Q. What do you find the maximum variation during any 24 hours to be?

A. I will give you the range of it in just a minute. The daily variation, as indicated by these scalings from the record of the recording gage varies from .18 for the 24 hours on the 7th of June, 1908, to 2.42 feet on the 14th of June; the change of 2.42 feet appearing in consecutive hours as did also a change of 1.24 feet on July 17th, a change of 1.16 feet on August 12th and of .89 of a foot on August 13th. A change of 1.44 of a foot occurred in two hours, that is between three consecutive hours, on July 7th, and a change of one foot

within two hours on July 13th, and numerous other smaller changes.

Q. How many days all together is covered by that?

A. Ninety-two.

Q. And for how many days do you find the variation more than a foot?

A. I will have to count them—15 days.

Q. How many days do you find more than a foot and a half?

A. Four.

Q. Now referring to table Number XLVII, being sheets marked Williams' Exhibit Cross Examination Number 1, on how many of the days where the variation was more than 1 foot were discharge measurements made?

A. 18 observations, which were taken on six days.

Q. That is 18 observations you say?

A. Yes.

Q. Out of a total of how many?

A. 78.

Q. 18 out of a total of 78?

A. 18 out of a total of 78, yes, sir.

Q. And as to the 60 other observations, the variation on the day on which they were taken was less than a foot?

A. That is correct.

Q. On how many of those days when the variations were more than a foot was the variation during the day time on the dates on which observations were taken?

A. I could not say without an examintaion of the table. That particular inquiry was not contemplated when these figures were prepared, and they do not give the information.

Q. There are only a few days. I will ask you to look at that, so that we can get it into the record now.

A. There is nothing on the chart to indicate what is noon. I think there should be a statement to show that is noon. A man might start them at midnight.

Q. The hours on these sheets are numbered from 1 to 24, commencing, as I understand it at midnight. Is that your understanding about it?

A. That is my understanding now.

Mr. Adcock: Subject to verifying that statement.

Mr. Shenehon: The first hour is one o'clock in the morning.

The Witness: I am so informed by the complainant's principal witness.

Mr. Wilkerson: With that in mind, answer the question.

A. Just what is the question?

Q. (Question read as follows: "On how many of those days when the variations were more than a foot, was the variation during the day time on the dates on which observations were taken.")

A. On five days covering 16 observations.

Q. So far as the element of the movement of Lake Erie is concerned, what is your judgment as an engineer of the effect of that upon the accuracy of the 60 observations, where there was a variation of less than a foot in 24 hours?

A. I don't see as the fluctuation of the lake had very much to do with the discharge observation; that is with the accuracy of the observation itself.

Q. That is to say the accuracy of the observation was not in your judgment materially influenced by that element?

A. That is my view of it.

Q. I think there has been submitted to you, Mr. Williams, and you have been asked to check the correctness of, certain computations in which the level of Lake Erie has been computed from the discharge measurements by means of a certain law, which is taken as the law expressing the relation between the level of the lake and the volume of the discharge; and you have also checked the elevation of Lake Erie as thus computed against the observed elevation of Lake Erie for the same time. I ask you to state, so that we may have it in the record, what was the law which was taken as expressing the relation between the volume and elevation of Lake Erie?

A. The law which was applied appeared to be the same and was certainly very similar to that presented on Complainant's Exhibit 3; being the discharge curve for the International Bridge Section of the Niagara River.

Q. Just look at it so as to make sure that it is the same law.

A. I did examine it. I say that it was very nearly, and it was assumed to be, and to all appearances was, very nearly.

Q. Substantially the same law?

A. So far as I was able to detect, and so far as the accuracy of the plotting could control, it evidently was the same law.

Q. Now, as to how many observations did you check the computation by which the elevation of Lake Erie was determined with reference to a given discharge?

A. 107.

Q. Over what range of lake elevations do those 107 observations extend?

A. The minimum of 570.03 to a maximum of 573.92.

Mr. Adcock: You have handed him something here; let us have that identified.

Mr. Wilkerson: I did not intend to put the whole memorandum in the record. The paper which the witness is examining is a memorandum, which shows the result of these computations. I think for the purpose of this inquiry it will not be necessary to put the whole computation in the record. I am merely going to have him state certain facts with reference to the computation which he has checked.

Mr. Adcock: I wanted to have a copy of that in our possession.

Mr. Wilkerson: You may look at it any time you want to.

Mr. Adcock: Will it be understood that we may have a copy?

Mr. Wilkerson: It will be understood you may have a copy of the memorandum, of any memorandum which the witness refers to, to refresh his recollection in testifying.

Mr. Adcock: All right.

Mr. Wilkerson: Q. Now, over what range of time do the 107 observations extend?

A. That I can't say. Have you got the dates in here? Substantially over the five years.

Q. Embraced by the observations which were taken on the Niagara?

A. The observations which were taken on the Niagara at the International Bridge Section.

Q. And used in this case?

A. Yes, sir. It does not however include all the observations, nor half of them.

Q. That is to say we have 107 observations taken out of 219?

A. That is correct.

Q. How nearly do you find that the elevation of Lake Erie as computed according to the law there stated corresponded with the actual elevation of Lake Erie, as measured at the particular time when the observation was taken?

A. On seven occasions, the computation agreed with the observed elevation of Lake Erie through the 100th place, which was as far as it was attempted to establish it.

Q. That is to say for two decimal places—

A. For two decimal places.

Q. It was zero?

A. Yes. The maximum error on the high side, that is the maximum amount by which the actual elevation of the lake

exceeded the computed elevation was .08 of a foot of the maximum—

Q. That is how much in inches? That is an inch?

A. This is feet.

Q. Approximately an inch, less than an inch?

A. .96 of an inch, slightly under an inch. And the maximum variation by which the computed elevation exceeded the observed elevation was also .08 of a foot.

Q. That is less than an inch, slightly less?

A. Just slightly less than an inch. The average variation was .042 on the one side, and .041 on the other.

Q. That is practically half an inch.

A. That is practically half an inch, slightly less.

Q. And there are about as many in which the computed observations were high—

A. There were 52 in which the lake was higher than the computed value, and there were 48 in which it was lower, and 7 in which they agreed.

Q. If you didn't know what the elevation of Lake Erie was in these 107 instances, how nearly would you be able to predict by the application of this law expressing the relation which we have under consideration the actual elevation of Lake Erie?

A. In all cases you would have predicted it within one inch. In approximately half of the cases you would have predicted it within one-half an inch.

Mr. Adcock: That is the Buffalo gage?

A. Yes, that is referring to the Buffalo gage.

Mr. Wilkerson: Referring to the Buffalo gage?

Mr. Adcock: That applies to these 107 observations?

A. Yes, applies to 107 observations.

Q. And as I understand it these 107 observations referred to are selected observations are they not?

A. I assume that they are.

Mr. Wilkerson: Q. So that if you took these 107 observations, and took the mean of the discharge observations, by the application of this law you would be able to predict the mean elevation absolutely, wouldn't you? It appears that you would be able to do so?

A. It appears that that would be the case. I do not see anything the matter with the mathematics of that.

Q. Now taking into consideration the range of these observations, nearly four feet, and the length of time over which they have extended, five different years, taking into consideration the fact that you would thus be able to predict

absolutely by the application of the law expressing the relation between volume of discharge and lake elevations which is here applied, what is your opinion as an engineer as to the conclusiveness of the law expressing that relation which has been applied?

Mr. Adcock: When you say "these observations" you refer to the 107?

Mr. Wilkerson: That is referring to the 107 at Buffalo?

A. As to mean relations between the discharge of the Niagara River at the Bridge Section and the elevations of the Buffalo gage under the conditions represented by these 107 observations, I would say that the law appears to be well established.

Q. Does it appear to you to be as well established for the upper end of the curve, that is to say for the higher water, as it does for the lower part of the curve, the lower water?

A. I don't think there is much if any difference.

Q. The one appears to be as well established—

A. The one appears to be as well established as the other.

Q. The one appears to be established with as great a degree of accuracy as the other?

A. Yes, I say I do not see any distinction between them, still referring to the 107 observations under discussion.

Q. You have spoken now in your testimony of the equilibrium of the river as one of the elements which has entered into the accurate determination of the law expressing this relation between volume of discharge and lake elevation. I wish you would state what you mean by the equilibrium of the river, as you have used the term, specifically the Niagara River.

A. I had forgotten just how I used it, at the present moment. Can you refer to the point where I did use it, whether it had any special significance.

Q. Is that one of the elements which you think enters into the determination of the accuracy with which this relation has been expressed?

A. What is the question?

Q. (Question read as follows): "You have spoken now in your testimony of the equilibrium of the river as one of the elements which has entered into the accurate determination of the law expressing this relation between volume of discharge and lake elevations. I wish you would state what you mean by the equilibriu mof the river as you have used the term, specifically the Niagara River?

A. I don't think I have used that term. I may have used

it; I will not be certain. I have in mind some sort of a definition of it at the present moment, but I would not want to give it here as referring to the use of it that I made the other day.

Q. Do you know what the relative fluctuations between the Buffalo gage and the Chippewa gage are?

A. I do not recall at this moment. Of course fluctuations at Chippewa would be expected to be materially less than they are at Buffalo.

Q. Do you think that a definite relation could be worked out as expressive of the relation that these fluctuations bear to each other?

A. I think it would be rather difficult on account of the rapidity of change at Buffalo. I think that anything that was worked out would show a less effect at Chippewa than actually would apply there for the Buffalo gage elevation.

That is, to state it this way, I think if you took the information you have and worked out that relation, and then it were possible to raise Lake Erie successively to the various elevations you have considered and hold it there, you would find a different relation existed between the Buffalo gage and the Chippewa gage.

Q. Are you familiar with the discussion of the slope relations of the Niagara River as set down in the document on the Preservation of Niagara Falls, the same being as I understand it a public document?

Mr. Adcock: The same being the one heretofore referred to.

Mr. Wilkerson: Senate Document Number 105, Sixty-Second Congress First Session?

A. I read that discussion some time ago. I can't say I would consider myself at the present moment familiar with it.

Q. If as a matter of fact a relation has been worked out which would enable you to predict with substantial accuracy from the elevation at Buffalo what the elevation was at Chippewa, would that indicate to you as an engineer that that relation had been established with satisfactory accuracy?

A. It would depend upon the amount of information that was used in establishing it. I can, of course, conceive of having a very large number of observations with varying quantity, where the effects of the excesses and the deficiencies may ultimately cancel each other, and you get to the effect of a true mean.

Q. I ask you to refer to page 41 of this document, Senate

Document 105, Sixty-Second Congress First Session, and direct your attention to the equations numbered 5 and 6 on that page?

A. (Referring to same).

Q. You have looked at those, have you?

A. Yes.

Q. I will ask you whether or not from an engineering standpoint, the check between the equation for 1906 and for 1906-7 is a substantially accurate and satisfactory one?

A. The variation in the computed elevation at Chippewa for elevation of Lake Erie at 573 seems to vary by about 1/10 of an inch.

Q. Between 1/8 and 1/10?

A. About 1/10 of an inch, and it would seem to be a very close check, and would indicate that the conditions covered in the two cases, or that the mean of the conditions covered in the two cases must have been very similar.

Q. By water leveling, can you pass from the Buffalo gage to the Cleveland gage?

A. If you have a sufficient number of the observations, with a reasonable degree of precision.

Q. Is it your opinion that we have a sufficient number of observations to pass from the Buffalo gage to the Cleveland gage?

A. I think with all that we have, we could.

Q. That is from the year 1887?

A. I think that ought to be sufficient.

Q. From that on to the present time. You think that should be sufficient for an engineer to do that?

A. That is you mean now in passing from one gage to the other, to say that—let's see if we understand each other: You mean by that to be able to say that the mean elevation at Cleveland corresponded with a certain mean elevation at Buffalo. But I doubt if we have enough observations to enable us to say that, when the gage at Buffalo reads, say 573, what the gage at Cleveland would read.

Q. Do we have enough observations to establish the ratio of fluctuations?

A. What do you mean by "ratio of fluctuations" in this question?

Q. The monthly mean.

A. For any month, you mean? That is from month to month? Yes, I think so. Wait a minute, hold on; I do not think that we have observations enough to be able to predict

from the monthly mean of the Buffalo gage what the monthly mean of the Cleveland gage is.

Q. For a season?

A. For a season you have, but I don't think that you have for a month.

Q. Having the observations for the season for Buffalo—or two seasons for Buffalo and Chippewa—can we establish that relation?

A. Can you establish what?

Q. The ratio of fluctuations.

A. As I said before, you can establish what the mean elevation of each gage is with reference to the other, but I question if you would be able to establish what the maximum elevation of one gage would produce on the other.

Q. Have you stated what the ratio of fluctuation between Buffalo and Cleveland is?

A. I think I have not.

Q. What is it?

A. I don't recall.

Q. Taking it for a single season, an open season?

A. Well, I should have to look at the gage records. I don't recall what the relative fluctuation at Buffalo and Cleveland is at all.

Q. Is it not a fact that it is unity?

A. Let us understand "fluctuation." I understand fluctuation to be the variation of elevation between the high and low of the gage. If we are understanding it the same, then my answer is correct, or at least I believe it to be. If you mean something else by fluctuation, then possibly my answer is not correct. If a thing fluctuates, we understand it to be vibrating back and forth. I don't know what the variation between high and low at Buffalo is, as compared with the variation between high and low at Cleveland.

Q. Well, can you establish the ratio, of annual or monthly mean over a term of years?

A. I don't think I got all of that question.

Q. (Question read.) That is to say over a series of months or series of years?

A. I think that taking the year as a unit, you can. I question if you can for any particular month.

Q. Isn't the lake substantially level?

A. Taking the year as a unit it is. If you take a month, I question if it is.

Q. With that understanding, isn't the ratio of fluctuations unity between Cleveland and Buffalo?

A. I don't understand your term "fluctuations." If at Buffalo the lake fluctuates 12 feet, and at Cleveland fluctuates three feet, it certainly is not unity.

Q. Take the same meaning that you had when you passed from Michigan-Huron to Erie, in your direct testimony.

A. That was the annual change of elevation; that was annual fluctuation, or other fluctuations from year to year over a long period of years.

I have already answered that question by saying that I thought you could establish it for a year; that I question if you could for a month.

Q. That is to say when Lake Erie is 571 over a term of months or years at Cleveland, it is 571 at Amherstburg or at Buffalo?

A. The average would be, I think.

Q. And the same for 572?

A. Oh, yes.

Q. Then the ratio must be unity?

A. Well, you are using the term "fluctuation" in a little different way. I would call them relation of stage rather than fluctuation.

Q. Well it follows then that if the relation between Cleveland and Buffalo is unity and the relation between Buffalo and Chippewa is .56, that the relation between Cleveland and Chippewa would be .56?

A. Just read that question.

Mr. Adcock: That is over a number of years.

The Witness: Over any time.

Mr. Wilkerson: Q. Over a period of months.

A. That is just a concrete fact there, that if the relations are so, then the things that are equal to the same thing are equal to each other. That is all there is to it.

Mr. Wilkerson: We will submit to you, Mr. Williams, between now and the next session, certain computations from which the Chippewa gage has been predicted from the gage at Buffalo, and checked with the gage as observed at Chippewa.

Adjourned to Wednesday, July 23, 1913, at 10 o'clock a. m.

Wednesday, July 23, 1913, 10:00 a. m.

GARDNER S. WILLIAMS, resumed the stand for further cross-examination by Mr. Wilkerson and testified as follows:

Q. In connection with these computations for the purpose of establishing the relation between the levels of the lakes and the volume of discharge of the lakes respectively, you made use of the method which is designated as the "Three Point Method," did you not Mr. Williams?

A. I never so designated it. I always called it the Center of Gravity Method.

Q. The Center of Gravity Method?

A. Yes.

Q. But it is the method—

A. The method that has been designated I think by the "Three Point Method" by some who use it.

Q. Where did you get that method?

A. I developed it out of my inner consciousness. I do not claim to be the originator of it, but so far as my use is concerned, I developed it myself. It is so simple, I assume many others developed it before me.

Q. Is it not in common use among engineers?

A. I don't know to what extent it is. It is an absolutely rational method based upon the fundamental principles of physics; and I don't know whether anybody else uses it or not.

Q. Do you know whether or not it is an accepted method among engineers?

A. I don't know whether—well, yes it is an accepted method, because it is an absolutely accurate method.

Q. Is it a generally accepted method?

A. It is accepted by anyone who has occasion to use it. It is the most accurate method of determining the line, the straight line which represents a series of observations, where all observations are given equal weight.

Q. In what technical publications is it described? I mean if as a student of mathematics I wanted to get some information about this method, where would I go to find some place where I could study it?

A. I do not recall at the present moment where it has been described. I think it will be found in some of the transactions of the American Society of Civil Engineers, and I think also in the Journal of the Association of Engineering

Societies, but I won't be sure as to the latter, whether it has ever been described there or not.

Q. By whom was the description written, if you remember?

A. I had in mind a paper of Mr. George H. Fenkell, but on second thought I rather think the method was not described there.

Q. Did you use it in the analysis of the pipe observations described in the transactions of the American Society of Engineers?

A. It was used there, yes.

Q. You used it?

A. I used it. In fact it was at that time that it was developed, as far as I was concerned.

Q. And Mr. Fenkell was in colaboration with you?

A. He was.

Q. Now on what process of reasoning does the validity of that method, in your opinion, depend?

Mr. Adcock: As applied to the proposition we have under consideration.

Mr. Wilkerson: No, I am speaking of this method, the method called the gravity method or the Three Point Method for deriving a relation between observations relating to two conditions?

A. On the theory of resultant force of a system of forces.

Q. Why do you have three points? Why aren't two enough?

A. Because you have to have three in order to make the division at the intermediate center of gravity to give the observations all equal weight. If you divided them arbitrarily, you would not be giving them all equal weight.

Q. If you should take your observations and divide them into two groups with the same number of observations in each group, would you not as a matter of fact get a line as accurately, to say the least, as you would if the result of that division of observations was to give the groups in which there would be an unequal number of observations in the respective groups?

A. I think not. When considering the moments which the various observations have about the center of gravity. The first thing that we do is to balance the entire series of observations about a point. That point then divides the groups, divides the observations into two groups. And we then find the straight line through the centers of gravity of those two groups. Thereby we get a mathematical balance; that is

we balance the whole system first about the center of gravity, and then balance each end about its center of gravity.

Q. You think the result arrived at by grouping the observations, whether you would have more observations in the one group than another, would be essentially a more accurate result than if the observations were divided into two groups, each containing the same number of observations?

A. I think that when the observations are divided by a line passing through the center of gravity for the whole group, at right angles to the direction of inclination of the average line that the division gives the most accurate process of determining the mean line that can be derived.

Q. You have spoken of the weight of the observations as referred to the distance from the center of gravity of the whole system. Doesn't that in your opinion mean that the range of observations in a given state in lake stage very greatly increases the weight of the observations, or the conclusions to be drawn from those observations?

A. Each observation is given the value which is represented by both its co-ordinates; does not depend upon the value of one. I think that answers your question.

Q. But the weight of the conclusion is greatly strengthened by range of lake stage in the discharge observations, other things being equal?

A. The weight of any conclusion as to the variation of discharge, with change of stage, is increased as you increase the range of the observations; other things being equal.

Q. When you spoke of the adoption of the method by Government Engineers in your direct testimony, what did you have in mind specifically?

A. I had in mind having seen a reference to it in some one of the Government publications. At that moment I was not able to recall it. I have looked for it, not very exhaustively, since. I don't find it where I thought it was.

Q. Was it among the Lake Survey publications?

A. I surmised that it was and looked for it there and didn't find it. Whether it was or not, I am not prepared to say at this moment.

Q. Isn't it a fact that the use, the only use which was ever made of it by the Government Engineers, was in an unpublished report by Mr. Richmond?

A. I doubt if that is where I saw it, although I may have. I have not read that report in full, although I have looked through it.

Q. Do you recall now whether the method was made use of in any way, in that report?

A. I don't recall that it was.

Q. So it is your recollection that appeared, or there was a reference to it some place else?

A. My recollection was that I saw it in print. I may be in error about it because I have only a very dim recollection.

Q. Aside from that indefinite recollection, you have no specific knowledge that the Government Engineers have accepted this as a recognized and established method for reaching conclusions such as are under consideration in this case, on a series of observations?

A. I have no specific citations.

Q. Do you know whether it is made use of by scientists in general for handling observations of the same general kind; by physicists, astronomers and other scientists who have occasion to derive laws from series of observations?

A. I do not. It is of course only applicable to straight line observations. It is not applicable to those where a curve would be the *locus*.

Q. Now there has been another method to which you have referred; there has been reference made to it throughout this testimony, called the method of "least squares".

A. Yes.

Q. Isn't it a fact that is the method which is in general use among scientists in dealing with a series of observations of the kind we have under consideration?

A. It is a method which is extensively used by some scientists in dealing with observations. But early in my career I had that method characterized in a manner which I must say it—I have found to be quite accurately descriptive of its use, in many cases where it is attempted to use it. An old Professor of mine said that the method of least squares was a device of lazy engineers to make up in the office for deficiencies in the field. And my observation of those men who have in the main introduced it into ordinary calculations has been that the intricacy and complication of the method has led them to lose sight of the fundamental physical elements which are involved in the problems being investigated.

I am not applying this criticism to such experts as some of the witnesses in this case, nor to many eminent scientists who use the method properly, and whose use of it no one would venture to criticise. But it is a method in which the

manipulations tend to obscure and smooth out and eradicate the characteristics of the original observations.

Q. It is a method however which has been adopted to the extent that a number of very eminent mathematicians have written books about it, and have given credit to it, is it not?

A. Yes, it is a very useful method, and is probably at the present day the most accurate one that we have for deriving the locus or equation where the locus is a curve.

Q. Is it still applicable where the line is a straight line?

A. It is applicable, but it is no more accurate than the method I have used, and involves very much more labor.

Q. That is your opinion, it is no more accurate?

A. That is my opinion of the matter, certainly.

Q. It is a fact that many of the laws which have been derived by scientists from observations have been derived from the method of lease squares, is it not?

A. It is.

Q. Who are some of the mathematicians who have written books giving validity to that method?

A. I don't know that I recall at the present moment.

Q. Do you recall Merriman's Treatises?

A. I would hardly classify Mr. Merriman as a mathematician.

Q. Who was he?

A. He was at one time Professor of Civil Engineering at the Lehigh University. He was the editor of the American Civil Engineers' Pocketbook. He is an author of certain treatises on certain engineering subjects and is the author of a book on the method of least squares. I never heard him classed as a mathematician.

Q. Perhaps there is something in the use of the word "mathematician" that involves a distinction in your mind. You spoke of the American Civil Engineers' Pocketbook, Mansfield Merriam Editor in Chief. That is a standard authority among those who make engineering and scientific observations?

A. I hardly think that the book has been in use long enough to be called a standard.

Q. You contributed something to it, didn't you?

A. I did.

Q. Is it a book that is in general use?

A. Becoming so.

Q. What I am trying to get at is this, Mr. Williams: We have a situation where it is necessary to determine a relation growing out of a series of observations. Now if we

wanted to find out the method which was to be used in deriving that relation, not by working out a method ourselves but by going to the authorities for it, where would we go to find a recognized authoritative way of deriving that relation except we go to these books on least squares, which have been written by Mr. Merriman and other men who have dealt with that question.

A. To determine a straight line passing through a series of observations, I would go to the fundamental principles of mechanics.

Q. Would the other scientists go there too?

A. I suppose they would.

Q. Isn't it a fact that the least squares is based on that?

A. In part, and in part on the theorum of probabilities which is a mathematical proposition as distinguished from a mechanical.

Q. Through how many editions has Mr. Merriman's book gone?

A. I don't know.

Q. It has gone through several, hasn't it?

A. I presume so.

Q. What other authorities are there in which this method of least squares has been considered?

A. I think it is generally discussed on works of mathematical astronomy.

Q. Chauvenet?

A. I think Chauvenet discusses it.

Q. Comstock?

A. I don't recall but I assume so because it is a process that is used particularly by the astronomers where they have to deal with complicated curves.

Q. How about Wright's Adjustment of Observations?

A. I am not familiar with it, but I would expect it would be practically certain it would be found in that.

Q. You have made a study of it have you?

A. To a limited extent.

Q. You have not studied the books to which we have been referring here this morning?

A. No, not to any great extent.

Q. Is it your opinion that assuming the accuracy of the observations, the curve derived for the Niagara River by the use of the method of least squares is rendered inaccurate because that method has been used in deriving the curve?

A. Not at all.

Q. Or in deriving a straight line?

A. Not at all.

Q. Treating a straight line as expressive of the relation within the range of the observations which have been studied?

A. Certainly. I have no criticism of the method of least squares, as far as applied to accurate observations.

Q. So that it is your judgment that so far as the determination of the relation for the Niagara River is concerned, it does not make any particular practical difference whether the method of least squares is used or whether the gravity method is used?

A. No, as long as you are confining both to a straight line relation. If you introduced the curve relation, then the method of least squares gives results which do not compare with the other, and which of course would be more accurate.

Q. You referred in your direct examination to the method of using a string as a method which was sometimes used, and it was referred to in the Government's testimony in this case. What part of the Government's testimony did you have in mind when you referred to this string method?

A. To the cross-examination of the Government's principal witness, Mr. Shenehon, in which I believe he used the expression: Stretch your thread or draw your line.

Q. I would like to have you refer to the particular part of the testimony in which there is that reference to this method which you have discussed in your direct examination, namely the use of the string?

A. I find your reference to threading the observation. Now, whether you used the word "thread" or not, I won't be certain; I mean in your testimony.

So far as a cursory examination of the record at the present time goes, I do not find a reference to either a string or a thread in the language reported as that of the complainant's principal witness. I find on page 251 the statement:

"After the observations as thus grouped are platted, a straight line is drawn threading these observations, and this straight line is taken to indicate the relation between lake elevation and volume of outflow."

It is my recollection that either in the record or out of it the witness explained that these lines were located by stretching a thread across the observations, and adjusting it by the eye to the position which seemed to most nearly fit the group of observations.

Q. Now in your testimony in which you have presented an analysis, a criticism from your point of view, of the work done by the Government Engineers in drawing conclusions

from these measurements, you indicated, as I understood you, certain reasons why the work of the Government Engineers was not to be accepted with full faith and credit. And among the reasons assigned by you was the one that the method which had been used by the Government Engineers was a rough method and not really very accurate, and that therefore these results were to be discredited for that reason. Was that what you had in mind?

A. To the extent to which they varied from a correct location of the line in question.

Q. And another reason which you assigned for discrediting the conclusions of the Government Engineers was that the method of least squares was not to be taken as an accurate method of combining these observations?

A. I think not.

Q. You had no criticism to make based upon the use of the method of least squares?

A. Except the broad one that the method of least squares in no wise compensates for errors of one sign.

Q. But you do believe that both of these two things, namely the extreme refinement of the method of least squares and the rough and ready method of using a string are sources of inaccuracies?

A. Not at all.

Q. In the work of the Government Engineers?

A. Not at all as to the method of least squares; it is not a source of inaccuracy; but it does not eliminate the inaccuracies that it is assumed to do.

Q. Have you ever made use of this method of drawing a thread through observations, yourself, in work?

A. Oh, yes.

Mr. Adcock: When you say drawing a thread through, how do you mean it is drawn?

Mr. Wilkerson: Q. You understand what I mean. You plot your observations and you take—

A. You adjust the line through by the eye, in order to have a line that can be shifted readily.

Q. And you use one that most nearly represents the direction represented by the observations plotted?

A. Exactly.

Q. You have made use of that?

A. I have.

Q. And within what degree of precision have you found you could get results, by doing that?

A. It depends very largely upon the manner in which your observations are located.

Q. I asked you within what degree of precision you found you would get a line that way?

A. I don't know that I have in mind the specific range.

Q. Would the line be likely to be wrong to the extent of 50 per cent.?

A. Hardly.

Q. Or 100 per cent.?

A. Oh, no.

Q. Or 25 per cent.?

A. Not likely.

Q. Or assuming the accuracy of the observations, in dealing with observations such as those we are dealing with in this case for the Niagara River, would it possibly be 5 or 10 per cent.?

A. I hardly think you would be as far off as 10.

Q. Do you think you would be as far off as 5?

A. Just what is that question?

Q. (Question read as follows: "Or assuming the accuracy of the observations, in dealing with observations such as those we are dealing with in this case for the Niagara River, would it possibly be 5 or 10 per cent.?")

A. The question is as to the Niagara observations as they are, as I understand it. I think in that case it should have been right within 2 per cent.

Q. Taking into consideration the 219 observations utilized at the International Bridge Section, what accuracy do you give to the center of gravity or mean of all of these observations?

A. Well, the center of gravity is the mathematical point at which the resultant or counter resultant of that system of observations considered as forces would be applied to balance the observations.

Q. In your judgment as an engineer, what accuracy do you give to the mean volume of flow at the mean lake stage of these 219 observations?

A. Somewhere inside of 20 per cent.

Q. I show you a chart, which for the purpose of this cross-examination I ask to be marked Williams' Exhibit Cross-examination No. 3; the same being marked: "Discharge measurements of the Niagara River plotted from the records of the United States Lake Survey, International Bridge Section, Buffalo, New York. Measurements of 1898, 1899 and

1900 shown thus: By a circle. Measurements of 1907 and 1908 shown thus: By a plus mark. 101 measurements in 1898, 1899 and 1900; 118 measurements in 1907, 1908, making a total of 219 measurements."

I wish you would take this chart and assume that the observations have been accurately plotted; draw a thread which in your judgment correctly represents the law expressing the relation between the level of the lake and the volume of discharge.

(Chart shown to witness was marked Williams' Exhibit Cross-examination No. 3.)

A. That is between the level of the lake as indicated on this chart, and the volume of discharge as indicated on this chart?

Q. Exactly.

A. It is my opinion no line that can be drawn through those observations will represent that true law.

Q. Assuming they have been accurately plotted, draw a line which would represent the relation which is indicated by them.

Mr. Adcock: Don't you think that is too long to use a thread? Is the witness going to do this?

Mr. Wilkerson: He can have as many co-laborers or assistants as he thinks necessary.

(Witness draws line as requested.)

Mr. Wilkerson: Q. Will you please state what you have done, in response to my last question?

A. Will you take out the word "correctly" in your question? The point is this: I have drawn this as nearly as I can by the eye to what is a correct representation, but I do not want to say that it is a correct representation, because it is not. I object to the word "correctly."

Mr. Wilkerson: Well, take that out. We merely want your judgment in the drawing of the line.

A. If you will put it in this way: Will you draw a line which represents to the best of your ability the relation between the gauge height as indicated, or the lake elevation as indicated and the discharge as indicated?

Mr. Wilkerson: I will substitute that for my question.

The Witness: I have drawn such a line.

Q. Now, what does the line which you have drawn indicate?

A. This line passes through the alleged center of gravity of all the observations on this plate which I find to be indi-

cated by a star, and concerning which I am informed by the complainant's principal witness is the plotting of the center of gravity of these observations.

Q. You spoke of drawing that through a star which indicates the center of gravity. Would the line as you have drawn it have been substantially different, if that star had not been there?

A. Not substantially. I had as a matter of fact located the line within a very short distance of the star before I knew that it was the center of gravity.

Q. In accordance with the line which you have drawn, what volume of discharge is indicated by lake elevation 574?

A. 240,450 cubic feet per second.

Q. What is the volume of discharge indicated by lake elevation 570?

A. 154,000 cubic feet per second.

Mr. Austrian: Q. You are testifying from the plat in question?

A. I am testifying from what is indicated on that plat.

Mr. Wilkerson: Q. What is the increment which is indicated by the line, as you have drawn it?

A. 21,600 approximately.

Q. I am submitting to you, Mr. Williams, a computation of that increment by your three point method, and I will ask you to check the computation which is submitted to you and which for the purpose of the examination may be marked William's Memorandum Cross-Examination A, and after you have checked it to give us a statement of the increment for the Niagara as derived by the application of your Three Point Method. You find on the paper which has been submitted to you for examination a certain increment indicated. That would be 21,860?

A. 21,860.

Mr. Adcock: As I understand it, you have not checked those yet.

Mr. Wilkerson: Q. The memorandum submitted to you indicates an increment of 21,860 cubic feet.

A. I find on computation this increment to be 21,870.

Q. Assuming that the memorandum which has been submitted to you is accuraetly computed, I will ask you to state whether or not the increment derived by the Three Point Method is not substantially the increment which is indicated on Government's Exhibit plate number 3, showing the loss of

level in Lake Erie corresponding to loss of outflow in the Niagara River?

A. It is.

Q. And you understand that this is derived from the same 219 observations as was plotted on the chart which you have examined?

A. That is my understanding.

Q. Now that being true, isn't it a fact that this discussion of the method of stretching a string, and of the method of least squares, as compared with the three point method, is something which has no real substantial bearing upon the accuracy of the results which have been testified to by the Government Engineers in this case?

A. So far as the three point method and the method of least squares is concerned, my answer would be yes. I would say in a case of the importance of this, it does not seem to me that an engineer should rely upon the thread method for more than an approximate value.

Q. Would you regard it as an improper procedure for an engineer to take the thread method and see what it indicated; and use the result provided he found it tallied substantially with the result given by the application of the more intricate mathematical computation?

A. Oh, not at all.

Q. And for the purpose of simplifying evidence of this kind, wouldn't that be, in your opinion, the proper way of dealing with observations of this kind, to find the simplest method, one a layman could understand, and use that method and if he found on checking with the other computations that it was accurate, to make use of that method as explaining the way in which the law was derived?

A. I think as an illustrative method, its use was entirely correct.

Mr. Adcock: Q. But if it did not check what would you do about the line you had drawn, by drawing a string?

A. I would shift it until it did.

Mr. Wilkerson: Q. Assuming a possible inaccuracy of 2 per cent. in the computation of the increment due to the use of the string method or the thread method, what effect would that have upon the result as to the loss of lake level corresponding to the difference in the increment?

A. The error of increment—the proportionate error of increment would be the same as the proportional error in the lowering derived from it.

Q. And for a loss of level of four inches, say, the difference

would be 2 per cent. of four inches or .02 of 4 inches, .08 of an inch?

A. I think your mathematics is correct.

Q. Now, Mr. Williams, I wish you would draw on there with a dotted line or something, a line that would represent an increment of 34,000 cubic feet, the line passing through the center of gravity.

A. I have drawn such a line and marked it "Increment 34,000 c. f. s."

Q. In your opinion, does that line express the law of those observations, assuming the observations to have been made correctly and correctly plotted?

A. Not at all.

Q. With reference to the accuracy of the center of gravity, you stated in reply to a question that it was within 20 per cent. in your opinion. I wish you would state what in your judgment are the reasons for such inaccuracy, if there are any.

A. The difficulties of properly connecting the discharge at any given time with the elevation of the lake stage which produces that discharge, or the elevation of the lake surface which produces that discharge, and the difficulties of accurate measurement at the sections involved. Those are the primary elements; and the inadequacy of the number of points observed in the cross sections to determine the discharge accurately.

Q. Then there are two elements involved: One is the gage, and the other is the measurement of the volume.

A. One is the relation of the gauge to the discharge, and the other is the measurement of the discharge.

Q. Is the mean lake elevation indicated by these 219 observations practically the mean lake elevation at Cleveland?

A. For the same time?

Q. Yes.

A. I would expect it to be, approximately.

Q. Well, it would be so nearly it would not make any substantial difference in result.

A. I find on examination of the report of the International Waterways Commission on the Regulation of Lake Erie, tables X and XI, that the average elevation, the mean elevation of the Buffalo breakwater gage from 1860 to 1907, a very considerable portion of which has been derived by reference to the Cleveland gage, shows an elevation of the lake surface .07 of a foot higher than the elevation of the Cleveland gage as shown in table X.

I find that for the eight years from 1900 to 1907, inclusive, the average difference of elevation is .17 of a foot, and this in every case indicating the Buffalo water surface to be higher than the surface at Cleveland.

I find that this difference ranges from .05 of a foot in 1905 to .26 of a foot in 1906, those being the maximum limits of the range during these eight years. In view of that, I question somewhat whether one is warranted in saying that the indication of the Buffalo gage is to be taken as coincident with or corresponding to that of the Cleveland gage for the observations in question.

Q. What bearing do the years 1901 to 1906 have upon this inquiry which we now have under consideration?

A. The inquiry as I understand was whether or not the elevation as indicated at Buffalo for these 219 observations corresponded practically with the elevation at Cleveland at the same time; and I have examined the records of annual elevations of the two places for eight years, and I find this difference and as the result I draw the conclusion that they probably do not. I take these years as being the ones when there was a self-registering gage at Buffalo; and being the only ones when the self registering gage was there, during the entire year.

Q. Would it not be more pertinent to the inquiry to take the monthly mean of the gage for the months during which the observations in question were taken?

A. Yes, and more pertinent to take the daily observations at the two points during which they were taken.

Q. Is it not your judgment as an engineer, based upon an examination of these figures, that there is not a discrepancy of more than 1-10 of a foot between the Buffalo gage and the Cleveland gage, during the periods covered by these observations?

A. I have not examined the elevations of the Cleveland gage and the Buffalo gage critically for the periods covered by these observations. I would think that the probability was that the difference was greater than 1/10 of a foot.

Mr. Adcock: That is the mean?

A. The mean.

Mr. Wilkerson: Q. Do you think it would be substantially greater than 1/10 of a foot.

A. I am unable to say. I find differences here as the average of a year of .26 of a foot.

Q. Isn't it a fact if you take the Cleveland gage readings

during the period covered by these observations that they check very closely with the Buffalo gage observations?

A. I don't know.

Q. Isn't it your opinion that they do?

A. If you take the Cleveland gage readings during the times when the observations were actually taken, I think they do not.

Mr. Adcock: You are referring to the mean?

A. I am referring to the mean.

Mr. Wilkerson: Q. If those two gages were in substantial agreement during the time when the observations were taken, wouldn't that eliminate the element of fluctuation as governing the flow at the mean stage of the 219 observations?

A. It would not in my judgment.

Q. Why?

A. Because, as I have said before, we have no knowledge of what the stage of the lake is that corresponds to the discharge, except as it is secured by discharges carried over long periods of time, when this element of constantly changing lake can be eliminated by the balance of ups and downs.

If you will compare the continuous discharge of the Niagara River, measured for say a month, with the average elevation of the lake for that month, you should get an increment that would be somewhere near the approximately correct one, assuming the discharge observations to be correct.

Mr. Adcock: You mean at high and low.

A. Yes, if you compare the observations taken on the Niagara River for one or two or three months when the lake was at an average high stage, taking the mean of those discharges and the mean elevation of the lake for that period covered, and compare that with the mean discharges and mean elevations of the lake for a period of one, two or three months when the lake was at a low stage, and thereby derive an increment, you will be approximating to a correct increment, assuming that your discharge has been correctly measured. But so long as you are dealing with daily observations applied to daily gage readings, or to hourly observations applied to hourly gage readings, it is my opinion that you never can get a correct increment for Lake Erie, or any other of the Great Lakes.

Q. Throwing out of consideration the variation of discharge for the different lake stages, is it not your opinion that the Cleveland gage shows substantially the same elevation

during the times of the 219 observations under consideration as the Buffalo gage?

A. As I have made no specific comparison, I am not prepared to answer that question, and its answer would also depend upon the limitations that are put upon the word "substantially." If you mean within a foot my answer is yes. If you mean within 1/10 of a foot, my answer is no.

Q. Will you check up and make a computation as to the mean of the Cleveland gage, compared with the mean of the Buffalo gage during the times covered by the observations?

A. The following table represents the computation of the mean of the Cleveland gage compared with the mean of the Buffalo gage during the times covered by the observations.

Year.	Month.	Cleveland Elevation.	Buffalo Elevation.
1898	July	572.59	572.50
	September	572.01	572.08
	October	571.81	571.91
	November	571.69	572.01
	December	571.52	572.07
1899	February	571.46	571.59
	March	571.83	571.85
	May	572.44	572.32
	August	572.09	572.09
	September	571.85	571.90
	October	571.61	571.48
	November	571.62	571.55
	December	571.34	571.96
1900	June	572.47	572.41
	July	572.34	572.43
1907	October	572.69	572.79
	November	572.41	572.71
1908	June	.....	.....
	July	.....	.....
	August	.....	.....

Q. Now did you not state on yesterday that the relation between the volume of discharge and the level of Lake Erie at Buffalo was very definitely established by the computation of lake level from 107 observations of discharge, as stated by you in your evidence yesterday?

A. I think not. What I stated was that the relation between certain discharge observations and certain gage observations appeared to be very accurately established. I did not say that that was an establishment of the relation between

the level at Buffalo and the discharge at Niagara, as I do not believe that it was.

Mr. Adcock: These were the 107 selected observations you had?

Mr. Wilkerson: Yes.

Q. Now assuming that the relation between the volume of discharge and the level of Lake Erie at Buffalo was shown to be definitely established as was worked out on yesterday, and assuming that the stage at Cleveland is substantially the same as the stage at Buffalo during the times of the observations, wouldn't that indicate that you had a relation between the volume of discharge and the stage of the lake at Cleveland established?

A. I think not, for the reason that the simultaneous elevation of a lake with the discharge measurement is not the elevation that entirely controls the discharge.

Q. What do you mean by the term "entirely" as you have used it?

A. I mean when you consider simply the elevation of the lake at the moment the discharge measurement is taking place, you are ignoring the question of what the lake was doing during the antecedent minutes or hours, and thereby eliminating entirely the question of inertia, which is a very considerable one, as well as the question of the influence of elevations below the discharge station.

Q. When you said "not entirely," did you have anything in mind, any per cent.?

A. No.

Q. Is it about as substantial as the barometric column?

A. I think fully.

Q. And greater?

A. Very much. I think it is enough to change that increment from about 21,000 to about 34,000. And in bearing that out, I will show what just a little change will do.

During 1898, there were discharge measurements at Buffalo, from June 26th to August 6th. These were made, sometimes four a day, and ordinarily not more than one or two days was skipped.

Observations of discharge were made as follows: June 26th, one; June 27th, three; June 29th, two; June 30th, four; July 2d, four; July 6th, four; July 7th, two; July 8th, four; July 10th, four; July 16th, two; July 18th, two; July 20th, three; July 21st, three; July 22d, four; July 23d, four; July 24th, four; July 25th, three; July 27th, two; July 29th, two; July

30th, three; July 31st, four; August 1st, two; August 4th, four; August 5th, four; August 6th, four.

The mean discharge or the average——

Q. What year is this?

A. That is 1908. The average of all these discharge measurements is 223,774 cubic feet per second.

The average elevation of Lake Erie at the Buffalo gage for the same period, computed from the mean daily elevations is 573.26.

In 1898, between September 10th and October 21st, inclusive, there were observations made as follows:

September 10th, one; September 13th, two; September 15th, two; September 17th, two; September 20th, two; September 22d, two; September 24th, two; September 27th, two; September 29th, two; October 1st, two; October 4th, two; October 6th, two; October 8th, two; October 11th, two; October 13th, two; October 15th, two; October 17th, four; October 19th, two; October 21st, one.

The average discharge of all these observations is 190,097 cubic feet per second.

The average elevation computed from the average daily elevation of the Buffalo gage for the days included is 571.96.

The difference between the elevations in the first period, 573.26 and 571.96 is 1.30.

The difference between the discharge for the first period 223,774 and that for the second period 190,097 is 33,677.

33,677 the difference in discharge divided by 1.3, the difference in elevation, gives an increment of 25,900 cubic feet per second.

I submit, in my judgment, that is a more accurate increment than any that has been derived by the complainant in this case, and that it should be further corrected for the lack of more continuous observations, and a more extended period, to fully eliminate the effect of fluctuations on the Buffalo gage.

And it should be still further corrected by the necessary errors involved in the complainant's measurements of the Niagara Section.

Q. Do you think that 25,000 is more nearly accurate than 34,000?

A. I do not. I think that other is in the effects of these vibrations still that are not accounted for in this collection of data, and in the errors of discharge measurement.

Mr. Adcock: Do I understand if you had a great number of observations where the lake was at an even stage, low

stage, and a number of observations where it was at a higher stage, that you believe the increment would approach the 34,000 that you speak of?

A. It would, if the observations of discharge were accurate, but they are probably in error anywhere from 10 to 20 per cent., and therefore the increment is bound to be low.

Mr. Wilkerson: An error of 10 per cent. in the observations would make a difference, dealing with increments from 23,000 to 25,000, would make a difference of about 2,000 cubic feet a second, or a little more.

A. Depends altogether on how those errors were distributed.

Q. According to the law of probability, it would be so distributed it would tend somewhat to balance, wouldn't it?

A. That would depend upon whether the errors introduced greater effects at high discharges than they did at low, or *vice versa.*

Q. You have spoken of two kinds of fluctuations at the Buffalo gage, one of which you think affects the discharge and one of which does not. I wish you would explain just what you mean by that.

A. Well, the term fluctuation, as I have been using it recently, I have had mainly in mind what might be called vibrations or rapid changes of level. We also, unfortunately, used the term fluctuation to apply to the change of level in the mean from one year to another. That would be more properly——

Q. That is a variation of stage?

A. That is a variation of stage, and would more properly have been designated as the change of average annual elevation. I think in my testimony it was so designated; I endeavored to so designate it every time, in order that there might be no misunderstanding.

Q. So you have in your mind the distinction between the level of the lake at Buffalo at a particular time, and what might be called the stage of the lake?

A. I would understand by stage that average elevation which continues over an appreciable period of time, as say a month or a year.

We speak of monthly stages, and we mean the average elevation during that period.

Q. Now let us take this case: Take a difference of two feet in the gage readings at Amherstburg and Buffalo, the Buffalo gage reading 573. Now suppose at one time the Am-

herstburg gage read 571, and at another time the lake was level and the reading was 573, what in your opinion would be the effect of those two different conditions upon the volume of discharge of the Niagara, assuming that the 573 was continuous for several consecutive days?

A. You mean you are comparing two periods, one in which the lake is permanently tilted up to the extent of two feet in its length, so that the highest point, that at Buffalo, is at 573, with the case where the lake is level for several days, at the same elevation.

Q. Yes?

A. I would expect the larger discharge in the second case.

Q. You would expect to find a larger discharge during the period when the lake was level?

A. That is my opinion.

Q. To what extent? A. I am not able to say.

Q. Have you any definite opinion on that subject?

A. I have not except that it is one of the elements that accounts for the discrepancy between what the relations with the other lakes show to be the true increment of Lake Erie, and the apparent increment as derived from the observations that have been presented in this case.

Q. This example which I have given illustrates what you have meant by the two different kinds of elevations at Buffalo, the one where the lake is level and the other where it is tilted?

A. No, I don't think so; and I don't know as I used the term, two kinds of elevation. I think there is only one kind of elevation; that is when the water is up or down, or somewhere all the same level.

Q. This is so far as effect on the discharge is concerned?

A. That is only a part of the story, because in the actual procedure the lake did not generally remain tilted in this position for several days, but in fact was changed from hour to hour and day to day.

Q. Let us take over a period of one day then.

A. What is the question?

Q. The same question as I put to you before, taking it over the period of a single day?

A. I question, taking it over the period of a single day, whether in either case you would get the discharge that corresponded to the elevation of the lake, in either case.

Q. Why do you reach that conclusion?

A. Because it seems to me that it may take more than a

day for the full influence of change of lake elevation to make itself manifest in the discharge measurement.

Q. How would you establish that fact, by an investigation of the river slope, and other elements to be taken into consideration?

A. I don't think it can be established, because of the fact that the lake will not stand still long enough to let you establish it.

Q. Is it your opinion that the outflow of the Niagara River may be indicated by a gage at Chippewa?

A. I think so, subject to such variations in gage indication as would be due to changes in the flow of the Welland River.

Q. Do you know how large that flow is?

A. It is not large, but of course at times I would think it would cause an appreciable variation in the elevation of the gage. That is simply a judgment I have from looking at the map. An inspection of the locality might change my mind in regard to that entirely.

Q. Do you know whether there is an outflow of 100 cubic feet a second in the river, under ordinary conditions? It is a fact, isn't it, that the Welland Canal intercepts the river and takes off most of the flow?

A. I am not prepared to testify from personal knowledge in answer to either of those questions. My impression is that the flow of the Welland River on the average would not be more than 200 cubic feet per second; but the possibility occurs to me that in the event of a heavy local rain, or something of that sort, that the flow might be increased enough to affect the indication of the gage, and as I conceive, at Chippewa change of gage elevations will be comparatively small for changes of discharge. A small change in the elevation of the gage might have a significant influence upon the computed discharge of the river.

Q. That ratio is indicated by the relation of the gage at Chippewa to the one at Buffalo, to which reference was made on yesterday?

A. No, I don't think it is.

Q. Eliminating the Buffalo gage for the time being, may not the volume of flow be indicated by the gage at Chippewa?

A. I think so, if we had correct measurements to connect it with the discharge.

Q. By making the measurements at Chippewa and by measuring the volume of discharge at the International

Bridge, you can work out a relation between the stage of the lake at Chippewa and the volume of discharge, can you not?

A. Approximately.

Q. Within what limitations?

A. That would depend upon the influence of the volume between Chippewa and the gaging station that had to be filled with the flowing water before the full indication, the full effect of the increase or change of discharge would appear on the Chippewa gage.

Q. What is the source of inaccuracy?

A. The source of inaccuracy in connecting the discharge at Buffalo with the gage at Chippewa is involved in the volume of water that must be used in filling or emptying the prism of the river, to bring about the change in the Chippewa gage which corresponds to the condition at Buffalo.

In other words, if the discharge at Buffalo is that corresponding to an elevation one foot higher than corresponded to the elevation of the Chippewa gage at the time the discharge measurement began, then before the Chippewa gage would indicate the elevation corresponding to that discharge the water in the river must be raised by the addition to it of a volume whose base would be one foot at Buffalo, and whose area would be the area of the water surface between Buffalo and Chippewa, and whose lower edge would be the change of elevation of the Chippewa gage corresponding to the change of the foot at Buffalo.

This would take a certain amount of time and prevents the transmission of the measurement directly to Chippewa without an investigation and correction for this influence, the added or subtracted water depending on whether the water be rising or falling.

Q. For the river rising one foot in an hour, what would be the volume, the cubic feet per second, in the prism of water to which you have referred? I will ask you to compute that, and give the answer to the Commissioner, making an approximate computation?

A. It must be borne in mind that all the time that this water is rising, or being added, at Buffalo, it is also flowing away over the falls; that with each rise of the Chippewa gage, the flow over the falls is increased, so that it is not simply a measurement of the volume of that prism, but it is a computation of the volume of water that must be put into the river to fill this prism, which is more than the volume of the prism

actually is by the amount which flows out at Niagara over that which flowed out under the conditions with which you started.

Q. You will make the computation I have asked you?

A. I will endeavor to make it.

Q. How often do changes of a foot in the river come about, in your judgment?

A. Well, as I remember the testimony of yesterday, we found some thing like 18 of them in a matter of three months.

Q. The remaining days would be sufficient, wouldn't they?

A. Sufficient for what?

Q. To derive a relation between the Chippewa gage and the volume of discharge?

A. I think a relation could be derived.

Q. And if you did that the uncertainties as to Lake Erie's level would be eliminated, would they not, in the result?

A. They would be eliminated so far as the discharge of the Niagara River is concerned, assuming the discharge measurement itself to be accurate. But they would not be eliminated so far as connecting that discharge with the elevation of Lake Erie at the particular time of observation.

Q. In your judgment, Mr. Williams, may a relation be worked out connecting the varying stages of the lake at Cleveland with the elevation of the water, as indicated by the Chippewa gage?

A. I think so. You said "varying stages?"

Q. Yes.

A. Understanding stage to mean the elevation of the lake over a considerable period of time, as a month, I think that is correct.

Q. And if that were done, the effect would be to eliminate these inaccuracies which were due to the level of the lake at Buffalo, which you have specified in your discussion of this subject?

A. As a general proposition.

Q. That is to say, that a way of eliminating those inaccuracies would be to establish a relation between the gage at Cleveland and the gage at Chippewa, and having that relation in mind, to take that in connection with the volume of discharge as it was measured, and that would eliminate these inaccuracies due to the condition at the head of the Niagara River and Lake Erie?

A. To a very large extent, insofar as they affect the discharge measurements themselves.

Q. I will ask you to compute the elevation of the Niagara

River at Chippewa from the elevation of Lake Erie at Cleveland for the months of July and November inclusive, 1906. You may use for that purpose the elevations of Lake Erie appearing on page 93 of the report of the International Waterways Commission and you may make use of the law of gage relations established by the Lake Survey and described in the document entitled "Preservation of Niagara Falls," to which your attention has already been directed?

A. I will do so.

Q. Have you made the computation?

A. No, sir.

Q. Do you know whether it has been made or checked by Mr. Ayers, your assistant?

A. I know that Mr. Ayers has made some computation here with Mr. Shenehon. As to what that computation is, or what it represents, I am not informed at the present moment.

Q. This computation is a computation that as you understand has been made under an arrangement by which Mr. Shenehon and Mr. Ayers made some computation?

A. I assume so, but up to the present moment this computation has not been explained to me, nor did I know at the time it was made what it was, nor do I know what it is now, nor the result of it. And until I have an opportunity to examine it I am not prepared to testify about it. I presume in five minutes I will be ready to testify.

Mr. Wilkerson: We will adjourn for five minutes.

(After recess.)

The Witness: I now have made such computation.

Q. You are now ready to answer my previous question, are you, Mr. Williams?

A. The question I understood you to ask was if I would. I said I would. I now say I have made a computation.

Q. You have made the computation?

A. I have.

Q. What are the results of your computation?

A. The results of the computation indicate that for the period from July to November, 1906, and June to November, 1907, the monthly mean elevation of the Chippewa gage has been computed from the monthly mean elevation of the Cleveland gage by the application of the equation connecting the Buffalo gage with the Chippewa gage; and that the maximum variation of the computed elevation at Chippewa from the observed elevation was .18 of a foot, the computed elevation

being low; that the minimum was a check of zero in the second decimal place; and that the maximum excess of computed elevation at Chippewa over the observed was .07 of a foot.

Q. That is to say, Mr. Williams, you have been able in the manner indicated to take the water level at Cleveland, and from that to predict the water level at Chippewa, that is 180 miles across Lake Erie and 20 miles down the Niagara River, with a difference of 10 feet in slope, to within an inch?

A. In some cases the elevation being the monthly mean elevation, and not a daily elevation.

Q. The monthly mean elevation?

A. The monthly mean elevation. In one case, the error is something over two inches, but that is only for November, 1907. The others all falling within the inch.

Mr. Adcock: These were not daily or hourly elevations, but the monthly mean?

A. Monthly mean elevations.

Mr. Wilkerson: So that taking the elevation of Lake Erie as indicated by the monthly mean stage at Cleveland, and applying to that the relation between the discharge through the Niagara River, and lake elevation deduced by the Lake Survey officers, you find that you get a result as to the elevation at Chippewa which is precise, within the limits as stated by you?

A. Yes, sir.

Q. And the average of that is about a half an inch?

A. No, if you take them all in, it would be I think over one-half an inch; or, to state it another way perhaps would make it more clear: There are three months in which the computed elevation is within half an inch of the level of the actual. The others all exceed the half inch.

Mr. Adcock: How many months are involved?

A. Eleven months.

Mr. Wilkerson: What does that indicate to you, as an engineer, as to the correctness of the relation established between the stage of Lake Erie, as indicated by the gage at Cleveland, and the elevation of the Niagara River at Chippewa?

A. That, considering the monthly mean elevations at the two points, the relation is established with a reasonable degree of precision for gage comparisons.

Q. Well, is not the elevation of Lake Erie at Cleveland, as indicated by these monthly means, substantially the stage of Lake Erie?

A. That is what has been taken as representing the stage of Lake Erie.

Q. Have you computed the elevation at Chippewa from the mean elevation at Buffalo for similar months?

A. That computation has been made.

Q. And with what result?

A. It shows that for the period in 1906, July to November, inclusive, and the period in 1907, June to November, inclusive, the mean elevation of the Chippewa gage as being predicted from the mean elevation of the Buffalo gage, with a maximum variation of the computed from the observed of .03 of a foot, the observed elevation being greater than the computed; that both the computed and observed have agreed through the second decimal place on one occasion, and that on three occasions, the computed has exceeded the observed by .02 of a foot.

Q. That is to say from the mean elevations at Buffalo you have been able to predict the Chippewa gage within substantially a quarter of an inch?

A. That is correct.

Mr. Adcock: What is that monthly or mean?

A. That is the mean monthly.

Mr. Wilkerson: What does the accuracy of this prediction indicate to you, as an engineer, as to the reliability of the gage readings which are concerned here?

A. Why it indicates the probable accuracy of the monthly means of all the gages involved.

Q. Indicates a very high degree of accuracy, does it not?

A. Why it does not seem to me that is a high degree of accuracy for observations with a recording gage. You ought to get as close as that.

Q. What does it indicate as to the estimate of a relation between the monthly mean variations at Buffalo, and the monthly mean variations at Chippewa?

A. It indicates the establishment of a relation with a satisfactory degree of precision, so far as gage elevations are concerned.

Q. And I understand that the period covered is 11 months?

A. Yes.

Q. I show you two sheets, which for the purpose of your cross-examination I ask to have marked Williams Exhibit Cross-Examination Number 4, the same being the hourly water levels as recorded by self-registering gage at Chippewa, Ontario, during the month of November, 1906. And I am

using here photographic copies of those. These original documents have all been introduced in evidence in this case. One is for the Buffalo gage, November, 1906, and the other is the Chippewa gage November, 1906.

Mr. Adcock: Do I understand that the original of that has been in the record, or referred to in some way? I understand that is the first time that any gage readings of the Chippewa have ever come into the case, except so far as they have been referred to in the last day or two?

Mr. Wilkerson: However that may be, they are photographic copies of the hourly water levels, as recorded by the Government gages and are a part of the official records and reports of the Lake Survey office; all of which have been utilized in this case on both sides.

Mr. Adcock: Yes, there is no question about that.

(Document shown witness was here marked Williams Exhibit Cross-Examination Number 4; same consisting of three sheets.)

Mr. Wilkerson: Will you compute from the daily mean elevations at Buffalo the corresponding daily mean elevations at Chippewa and the Niagara River?

A. These computations have been made.

Q. And have been checked as correct, as you understand it?

A. As I understand it.

Q. In the same way as the other computations were made and checked?

A. I assume so.

Q. What range of elevation at Buffalo is covered by that sheet?

Mr. Austrian: As appears from that table.

Mr. Wilkerson: Yes.

A. I see that elevations 571.48 for a mean daily and 574.60 for a mean daily appear as the record of the Buffalo gage.

Q. That is a range of more than three feet?

A. Yes, about 3.12 feet.

Q. What do you find as to the agreement between the computed elevation at Chippewa and the actual elevations?

A. They agree within about two inches.

Q. Do you mean that is the agreement of the——

A. That is the agreement of the means of individual days.

Q. That is the mean agreement?

A. No, not the mean. I say that they all agree within two inches.

Q. That is the outside figure?

A. That is the outside figure.

Q. What is the average of the agreement?

A. There is one case in which the agreement is exact; I find two cases in which the agreement is exact; another case in which it is within .01. From a casual inspection, I would say that the majority of these computations agree within less than one inch. I find that 14 of the observations, including three which agree exactly, agree within half an inch.

Q. Well, you have been able then to predict from the Buffalo gage, the gage at Chippewa within this limit that you have just stated?

A. Based on mean daily observations.

Q. Now I call your attention particularly to the observations for November 4th. The mean is 571.48, the predicted elevation at Chippewa was 562.05, was it not?

A. Yes.

Q. The actual elevation, mean elevation, 562.09?

A. Correct.

Q. The difference being .04 of a foot, or less than half an inch?

A. Slightly less than half an inch.

Q. Well, take the observations for the 27th of November. You find the mean elevation at Buffalo 573.31?

A. Yes.

Q. You find the predicted elevation at Chippewa 573.07?

A. 563.07.

Q. 563.07, which corresponds exactly?

A. Exactly.

Q. With the observed elevation at Chippewa, is that right?

A. That is correct.

Q. Now we have a range there of more than 2½ feet in the two days to which I have directed your attention, have we not?

A. I think so.

Q. 2.53, is it not?

A. You started out with the fourth, did you?

Q. 571.48, 573.31, difference 2.53?

A. I thought you were referring to this same pair that we had before.

Q. My question is how much of a range do we have?

A. You are referring to those two observations you just cited, or the entire range of the series.

Q. The two just cited.

A. I make that 1.83 feet.

Q. There is a range of 1.83?
A. That is it.
Q. Well, now, I direct your attention to the 22d.
A. Twenty-second of November?
Q. You find the mean elevation at Buffalo 574.60.
A. Correct.
Q. The predicted elevation at Chippewa 563.79; the observed elevation at Chippewa 563.92?
A. About an inch and three-quarters.
Q. What was the range between the 4th and the 22d?
A. 3.12 feet.
Q. 3.12?
A. Yes.
Q. Are these daily mean elevations what you could call a stage of Lake Erie?
A. Not according to the definition that we have been applying the word stage to. I would call them elevations. Of course you could call them daily stages if you want to.
Q. They would be daily stages?
A. Daily stages.
Q. The average daily stage of the lake?
A. The average daily stage of the lake.
Q. At Buffalo?
A. At Buffalo.
Q. Having in mind the data to which your attention has been directed in connection with this cross-examination, what is your opinion as an engineer as to the correctness of the formula or law by which the mean elevations at Buffalo have been connected with the elevations at Chippewa?
A. I think it is about as close as could be derived.
Q. And would indicate, from an engineering standpoint, a high degree of precision, would it not?
A. The characteristic precision of the United States Lake Survey.
Q. Now, the monthly mean elevation of the lake at Buffalo was 572.319?
A. That appears to be stated on the second sheet of this exhibit.
Q. How much above the mean was the mean level on the 22d and the 27th, above the monthly mean?
A. On the 27th, it was roughly a foot; and on the 22d roughly 2.3 feet.
Q. Now is it your opinion that under those conditions Lake Erie was tilted up, as you have been using that term?

A. Well, I could not tell without reference to the Amherstburg gage. I suspect that it probably was during the higher period.

Q. How else could the elevation at Buffalo be accounted for, except that the lake was tilted up?

A. Being November, I think it would be rather difficult to account for it in any other way.

Q. Then it is your opinion that those mean observations for those two days indicate that at those times the lake was tilted up?

A. I think so.

Q. And this indicates that even with the lake in that condition, the slope relations are maintained between the Buffalo gage and the Chippewa gage?

A. Within the limits shown in this comparison.

Q. Which are very close?

A. Well, that depends again on your definition of "close."

Q. As closely as you have pointed out? On the 27th it corresponds exactly, doesn't it?

A. I haven't the exhibit here at this moment.

Q. The 27th is the day on which we found the computed elevation at Chippewa corresponded exactly with the observed elevation?

A. On the 27th they corresponded exactly, that is certainly a very close coincidence.

Q. Well, now, you could go from the Chippewa gage to the Buffalo gage in the same way, could you not, Mr. Williams?

A. In the inverse way.

Q. Yes. The Chippewa gage is in a secluded position, and what would be your opinion of the results which you would reach if you worked back from the Chippewa gage to the Buffalo gage?

A. You mean results as to what?

Q. As to getting an accurate expression of the elevation of the lake at the Buffalo gage, the stage of the lake at the Buffalo gage?

A. For these particular observations, I should expect, if you worked them backwards, you would get the same result as working them forward. I do not see anything in the process which would lead you to anything when you add a certain quantity and then subtract the same quantity from the result, I do not see why you would not arrive at your original quantity.

Q. And in the absence of the Buffalo gage, you would be

able to predict substantially what the level was at Buffalo, would you not?

A. Within three or four inches.

Q. And at the outside, and with the same degree of precision as indicated with respect to predicting the Chippewa gage from the Buffalo gage?

A. Well, I consider that a comparison of 30 days is hardly sufficient to warrant one in saying what you could do generally. In these particular cases, you would have done so and so.

Q. Have you made any examination of this subject for the purpose of determining whether or not the results which are reached with the observations of 1906 as a basis, would be substantially the result reached at other times?

A. I have not, but I have no reason to expect that there would be very marked deviations.

Q. Now, Mr. Williams, you have computed the elevation of Niagara at Chippewa from the monthly mean stages at Cleveland with a certain degree of accuracy, to which you have testified; and with a still higher degree of accuracy, you have computed the elevation at Chippewa from the monthly means at Buffalo; and you have also computed with a degree of precision, which you have stated, the daily elevation at Chippewa from the daily mean at Buffalo, even at times when Lake Erie was tilted up to the extent of a foot or more. What is your conclusion as an engineer, having that in mind as to the identity of effect in outflow conditions in the lake elevations at Buffalo, whether the lake is tilted up or not?

A. Having in mind the fact that the computed differences on the daily observations are something more than 100 per cent. greater than those on the average monthly, it appears to me that it does indicate an influence due to tilting of the lake.

Q. How large an influence, now that this additional data has been called to your attention, do you think there is?

A. That is very difficult to say, because there is an effect of tilting in both, and you haven't got it eliminated in either case, so that it is not possible to make a direct comparison. The one in which the effect of tilting seems to be the larger seems to increase the error of the computation, as I said, about 100 per cent.

Q. Does it apparently increase or diminish the discharge?

A. In the one particular case of the high elevation, it appears that the discharge is increased, due to the tilted position

of the lake; and in the case where the lake is 1.1 foot lower, the computed agrees with the observed.

Adjourned to Thursday, July 24, 10 o'clock a. m.

(In chronological order, here follows the testimony of Mr. Joseph Ripley on Thursday, July 24, and the morning session of Friday, July 25th.)

After Recess Friday, July 25, 3 p. m.

GARDNER S. WILLIAMS resumed the stand and testified further as follows:

Mr. Wilkerson: Q. I wish to call your attention to a paragraph from Appendix Number 7 to the Report of the Board of Engineers on Deep Waterways Part 1. Appendix Number 7 is signed by C. B. Stewart, Assistant Engineer; page 299, referring to the discharge measurements made in the Niagara River at Buffalo between the dates September, 1897, and September, 1898, at the discharge section on the line of the guard rail, on the north side of the International Bridge. The paragraph is as follows:

"Eddies are produced by the piers, to some extent, but they do not extend more than about 5 feet from the pier, and in most cases the current remains practically linear, with about the same amount of fluctuations as near the middle of the span. It is thought that little error has been introduced from this source."

I will ask you whether or not in reaching your conclusion as to the measurements in the Niagara River you had in mind that statement?

A. I did not have that particular statement in mind when I made that answer, but I had in mind statements made or appearing in a paper read by Mr. Clinton B. Stewart, before the Western Society of Civil Engineers on December 20, 1899, or some three months after the date of this Appendix, in which it is stated, first:

"For the location of the stations on the discharge section, the shorter spans 1, 2, 3, 7, 8 and 9 were divided into eight equal parts, and the longer spans, 4, 5 and 6, in 12 equal parts; thus making the distance between stations about 20 feet. These stations were marked on the guard rail, etc."

Then later he says, speaking of observations with the direction current meter:

"The direction was practically constant between the 2-8 and 6-8 stations of the short spans; and between the 2-12 and 10-12 stations of the long spans. Next to the piers, the direction was somewhat variable, and the meter would swing through an angle of 10 or 15 degrees. In such cases, the mean of several determinations was taken as the direction."

Now, the stations being 20 feet wide, I would interpret that as meaning that between the 2-8 station it was constant, but it was not constant between the 0-2, or for a distance of about 40 feet.

Mr. Wilkerson: May I see the pamphlet from which you have just quoted?

The Witness: (Handing document to counsel.)

Mr. Wilkerson: Q. I direct your attention to page 488 of the document from which you have just quoted, which is a written discussion by Mr. E. E. Haskell of the paper of Mr. Stewart, from which you have quoted, and ask you to read the paragraph which I have marked there into the record; and I will ask you whether you had that statement of Mr. Haskell's in mind when you criticised these Niagara measurements?

A. (Reading.) "In regard to the bridge section, it is a much better one for discharge work than many would suppose. As Mr. Stewart has shown in his paper, the current sets very squarely through the bridge in all spans. Aside from the small eddies along the sides of the piers, and those caused by the sunken caisson, there were few of any magnitude to be seen. The ease and rapidity and the small expense with which observations can be made from such a bridge are a large consideration. The meter can always be set at the same point for a station, and in general the time required for measuring a full discharge is very much less than in work from boats."

That is quoted from a discussion by Mr. E. E. Haskell.

Q. Did you have that in mind?

A. I did.

Q. Now I call your attention to the report of the Chief of Engineers United States Army for the year 1900, page 5332. I direct your attention to the following statement commencing on page 5332:

"The analysis of meter positions was first made by Mr. C. B. Stewart in discussing the Deep Waterway observations

on this river, and out of this germ has been developed our own tables for meter location and a static method of sounding."

A. I had and also the next paragraph of the reference.

Q. If you will go ahead and read, or I will read it:

(Reading.) "The wetted perimeter of the Bridge Section, as developed by the soundings, is so broken and irregular, and the water is so perturbed and deflected by the bridge piers, and by a caisson that escaped during construction, and lies across a portion of span 6, that the validity of results derived from such a section may be questioned.

A discussion of this point, however, points to an error to be expected from this source but little in excess of that of an open-river section.

Let it be assumed that the eddies and boilings close to the piers make correct estimates of the flow impossible in areas extending for certain distances from them, and that the caisson lying across a portion of span 6 adds another uncertain area. The resulting indetermination as affecting the total volume of flow may be closely estimated as follows:

Taking the doubtful regions as those portions of the cross sectional area extending 10 feet in spans 1, 2; 8, 9, and 20 feet from the piers in the remaining spans; adding 300 square feet for the caisson, they are as follows:

	Square feet
Span 1	90
" 2	110
" 3	500
" 4	680
" 5	960
" 6	940
" 7	440
" 8	340
" 9	200
Total	4260

This is about 10 per cent. of the total cross section. With a velocity taken as half that of the mean velocity of the river, the discharge in question is 5 per cent. of the total volume.

It is not probable that the errors in estimating the flow in these 19 doubtful places will have the same sign. In some the quantity will be taken too great, and in some too small, so that the summation will balance error against error and eliminate a part of them. It will therefore be entirely safe

to assign 10 per cent. as a maximum error in the sum of the partial discharges.

With this liberal allowance, the indetermination in the volume of flow in the full river from this cause is seen to be 10 per cent. of 5 per cent., which is but ½ of 1 per cent."

Did you have that in mind?

A. By whom is that report signed?

Q. By Francis C. Shenehon, assistant engineer, and Mr. E. E. Haskell, assistant engineer, signed on page 5361?

A. I had that in mind, and also what to me seems a much more correct description of the conditions, which is to be found at the top of page 5342 which has already been read by me into the record. And I want to say that at the time I read that in, there seemed to be an idea that I was attempting to criticise the language. I read it because to my mind it was a most exact description of the conditions which existed between the bridge piers of the Niagara River; not with the idea of criticising the rhetoric or description but, as I say, now, as a most exact description of the conditions that existed in the Niagara gaging station, and as they were believed to exist by Mr. Shenehon, at the time he wrote this report.

Mr. Adcock: What is the quotation you refer to? Just read it.

Mr. Wilkerson: Q. What you read as justification for your comment on the measurements in the Niagara River was the general statement, whereas in both the writings of Mr. Shenehon and Mr. Haskell, and in those of Mr. Stewart, we do have a specific statement of the precise conditions, and of the error which it was deemed might possibly result from the difficulties.

Now, isn't it your view, if you were going to get a correct expression of an effect, you would go to that portion of the report which gives the data.

Mr. Adcock: What is the quotation referred to, Mr. Williams?

A. (Reading.) "In such a section as that of the International Bridge, the proper derivation of the velocity coefficient is the most difficult part of the river gaging. To obtain it, the writhing mass of water streaming through the bridge openings and eddying about the piers, spurting and lagging in minor pulsations, speeding faster as the lake rises, and flowing leisurely in its low stages must be congealed to a solid by some instantaneous method of survey, and its dimensions taken."

Now that is also signed by Francis C. Shenehon, assistant engineer, and Mr. E. E. Haskell, assistant engineer, and occurs somewhat later than this exact computation of the effect of these disturbances; and I would assume that the man, as he went on with his work, became more qualified to pass judgment on what he has done; and these concluding statements, these later statements were entitled to as great weight as his earlier ones.

Furthermore, from my personal investigation of the Niagara section, of the conditions of the river as I have passed over the bridge in the cars in the day time, and have seen the eddies come up to the surface, not only at the bridge piers, but elsewhere, I am convinced that the description on page 5342 is a correct description and that the estimates made on page 5332 are not sufficient to account for the errors introduced into the gagings by these oblique and turbulent currents.

Q. I direct your attention now to page 5361 of the report, which appears to be later than page 5342 of the report, and call your attention there to the paragraph where it says:

"It is exceedingly satisfactory to be able to report so close a check in the results of the measurements of the two sections."

A. Just where is that?

Q. Page 5361.

A. Yes, I see it now; I have got it.

Q. (Reading.) "The sections are very different, and received different methods of treatment. The Bridge Section index velocities depend on the B meter under the Detroit rating of this instrument by an excellent observer.

The open section velocities depend on the A meter, on the Buffalo base, by different methods and by different observers. The Bridge measurements were in 1898. Those of the Open Section, in 1899 and 1900. The former was from a fixed structure, the latter from a survey boat, whose influence on the current lines might be a factor in the result. The coefficient work has some elements common to both, especially the rating of the traveling meter. Yet it will be seen by a reference to the tables 4 that the co-efficients would not be appreciably changed by using any other established rating for the traveling meter. The co-efficients in both sections have been established by overwhelming numbers of observations, by accurate methods, and were derived by different methods of reduction.

Having a splendid equipment, the entire work has been carried out with greatest attention to fundamental principles and to details, and with the infinite patience demanded in gaging the many moods of this great river."

Did you have that in mind?

Mr. Adcock: What is the report signed by?

Mr. Wilkerson: By Mr. Shenehon and Mr. Haskell.

A. I had that in mind, and also this at the top of page 5334:

"The B meter is credited with a somewhat greater range in its diurnal fluctuations"—I don't know what the diurnal fluctuations are, but evidently are something or other—"And has a remarkable record for the pertinacity with which it clings to a mean rating. The original calibration of this instrument was in September, 1898. In February, 1900, an elaborate rating gave a value to the mean wheel revolutions but one per cent. different from its original rating. In the interim, the meter had suffered the vicissitudes of gaging a wicked section; it had been fouled on a ragged bottom and caught in the sheet iron sheathing of a bridge pier; had bent the blades of its wheel, and had then retrued; it had lost its tail and had it replaced by a somewhat different one; its standard lead had been changed for one three times as heavy; its pivot had been dulled by passing upwards of 5,000 miles of current thread through the wheel."

In view of that, it does not seem to me that was a particularly delicate instrument, nor one which would respond readily to these changes of velocity to which it was subjected. That it was, in fact I would almost call it a crude instrument, and it does not seem to me that this extreme exactness that is claimed can be predicated upon the work of an instrument which would stand any such handling as that; nor do I think that shows particularly good handling.

Mr. Adcock: How about the use of an instrument that had been through all that trouble?

A. (No response.)

Mr. Wilkerson: Q. Let me read some more:

"The strength of the instrument may be judged by this test; its sensitiveness may be gathered from its rating observations. These are necessary in order to interpret the registered revolutions as the meter spins in the stream into length of water thread, and thus obtain the speed of the current in feet per second."

The point is that in these reports with reference to these

measurements, it has been stated with exactness the data as to the error which might result from the section being located where it was; and also it has been stated that that checked with another section, and is that not the thing that is to be taken into consideration rather than any general statements about the appearance of the river?

A. I think not. One does not—

Q. The appearance of the river next to the piers?

A. One does not need to be told that there are oblique currents, or are not, when we can see the visible evidence of them on the surface of the river. When an eddy reaches the surface, it is an indication of a disturbance further down, and those disturbances in the water decrease as they pass away from the point where they originate, so that if an eddy appears on the surface, you can be sure that there was a much larger one where it started from, near the bottom. As to this analysis as to the effects and so on, that is the opinion of the observer.

So far as the comparison of the two sections is concerned, the Open Section was not far enough away to be entirely free of the same influences that caused disturbance in the Bridge Section.

Further than that, it is checking the same tool against the same tool, which is no check at all. It is simply two measurements with the same thing.

You may take a yard stick that is an inch short and measure the width of this room, and go out in the hall and come back and measure it again and you will get the same width; but the width will not be right. That is the situation here. You take an instrument that you do not know whether it is right or wrong. You measure, and you get a certain result. You go somewhere else and measure with the same instrument and get a similar result, and call that a check.

Now, it is a check upon the performance, the manual performance of the operation and a check upon the mental operations used in its reduction; but it is not a check upon the instrument itself nor upon the accuracy of the result. On the direct line between the accuracy of the work and the accuracy of the result, this work was very accurate. The result I do not believe to be accurate.

And furthermore I will say that had these results been made with a Price meter, which we all recognize would not have agreed with this within probably 3 or 4 per cent., every check that has been applied in this case could have been

applied to those results, with equal facility and equal agreement. If it had been made with a meter which registered 20 per cent. over the Haskell, every check that has been applied in this case could have been applied then. As far as these checks are concerned, you are simply jumping over a fence and then crawling back under it, and that is all there is to it.

Q. Let us take the case of the St. Clair River where there are such differences in velocities as are found in the different cross sections which have been measured there. Does the fact that a comparison of those results shows accuracy of the measurement within comparitively small limits have any effect upon your mind in reaching a conclusion as to the credit which may be given to water measurements of this kind?

A. They have. But the same thing applies there; that it is the same instrument and the same operation checked against the same instrument and the same operation.

Q. But under widely different circumstances?

A. Not very widely different circumstances. Let us assume that you had a meter there that registered 20 per cent. more, which rotated sufficiently more easily to have registered 20 per cent. more in the same current; and that by some mistake or other the rating of an instrument like the one here had been applied to it, your discharge would have been 20 per cent. greater, and every comparison you make now could have been made then; every check applied that you made then you could make now, and similar results obtained, but it would not have been an indication that the measurement was correct there. But these checks you have applied indicate exceptional workmanship; that the work has been very carefully done, but there were conditions there beyond the control of the observer.

Q. How far out of the way do you think on the average, as a general rule, these current meter observations have been?

A. In the large rivers?

Q. In the large rivers?

A. I think about 10 per cent.

Q. You think there is a possibility of their being 10 per cent. out of the way or as a matter of fact they have been 10 per cent. out of the way?

A. I think as a matter of fact they have been. I think it is very doubtful if there has ever been one made that was within 5 per cent.

Q. Have you been influenced in reaching that conclusion by the tests which were made on the Detroit River, and which

have been put into the record in this case; that is rating the current meters in the current itself?

A. You mean by the coloring matter, by the use of coloring matter?

Q. Yes?

A. I have, but bearing in mind that in the measurement of the Niagara River, the cross section of which was, if I remember correctly, something over 40,000 square feet, that there were actually occupied positions in that river by the meter of—while I will not undertake to be definite, I will say less than a thousand square feet were actually covered by the position of the meter wheels, at any time during the observations.

The current meter is an inferential device. It is not an absolute device that measures the velocity at a certain point, and it may measure it more or less accurately, but if it does, if you have only occupied 1 foot out of every 40, you cannot say within 5 per cent., or even within 10 per cent., that the velocities of the other 39 feet are the same. There you have got the measurement of 1 foot, and 39 feet that you have not investigated.

Now I say, gentlemen, that the chances of your getting within 5 per cent., or even 10 per cent. under those circumstances is extreemly remote, and I base that opinion, not only upon all this information, but upon my experience in measuring the velocity of water by inferential measurements, where the area of the cross section was absolutely determined, and where the quantity of water measured was absolutely determined.

Q. Is it your opinion that the Haskell meter registers, as a general rule, too high or too low?

A. Well, as a general rule, taking it in smooth water and without disturbances, it depends on its rating. If it is properly rated, it registers very nearly what it is rated, but when you apply to still water ratings or those taken at the surface of a body of water the conditions that the meter meets submerged 40 feet below, in a turbulent current, I feel that there is no reasonable comparison, that there is no limit that we can set upon the variation which that meter may show from the rating which it showed at the surface.

Q. If comparison of these conditions of turbulence shows the meter sometimes registers too high, and sometimes registers too low, isn't it a fact that is well understood in combining observations of this kind that the error on the one side

at one time is compensated by an error on the other side at another time, and in the long run these errors cancel each other to a large extent?

A. I see no reason for believing those particular errors would cancel each other. All the information I have indicates to me the meter registers low in those disturbed currents.

Q. Let us assume that the meter registers low a certain uniform per cent. low, if you used that meter over a long period of time, when speaking of relative results, you would have the same element, that the meter registers too low through all of them, so that for purposes of comparison the error in your reading is not such a material matter?

A. For purposes of comparison of one section with another, that is of very little consequence, but that has nothing to do with the measurement.

Mr. Adcock: The measurement would be too low?

A. The measurement would be too low.

Mr. Wilkerson: Q. And the measurement at another time would be correspondingly too low?

A. Yes.

Q. So that the difference would be about the same as if the meter had registered right?

A. That depends altogether upon the percentage by which the meter registers low. The difference will be affected by the same error that there is in the original registration.

Q. That is to say if you were comparing observations where there was a difference of say 40,000 cubic feet a second, and your meter was 5 per cent. out of the way, it would affect that difference by 2,000 cubic feet?

A. Exactly.

Q. As to this other point which you make, that you have measured only a small part of your cross section, and that it is unfair to assume that from measurements on a small number of points in a cross section you can reach a conclusion as to the entire body of water that goes through, have you been influenced in reaching your opinion by the corroborative check of the different cross sections of the rivers which have been measured, as the St. Clair River? Wouldn't that indicate that it is a proper process of reasoning to assume that the average of the conditions at the points measured is substantially the average condition of the whole cross section. Wouldn't these corroborative checks tend to show that you might properly use that method of reasoning?

A. I think not, because you would find if you adopted some

one point in the cross section, and used a meter only at that point, that your gagings would coincide more closely than they do when you use several points. And if you were to use a thousand points in a gaging, and compare it with another gaging in which you used a thousand points, those two gagings would not correspond as closely on an average as they do, perhaps, when you use twenty or forty points.

Q. You do not attribute to any inaccuracy in the rating of the meter any such difference in results between the increments in the Niagara River which you reach, and that reached by the Lake Survey, do you?

A. I don't know where to place it. I feel very sure that it is there.

Q. Do you think there is any possibility that any appreciable part grows out of the inaccuracy in the meter measurement?

A. I think that an appreciable part of it has come out of inaccuracy due to applying a rating over a straight course to the indications of the meter in disturbed water.

Q. I direct your attention to page 74 of the "Preservation of Niagara Falls", the same being a Senate document heretofore referred to in the evidence in this case; chapter 15 the first paragraph of which is:

"The hydraulic work of the Lake Survey on the outflow of the Great Lakes depends fundamentally for its accuracy on the proposition that the Haskell Current Meter rated on a still water base gives the true velocity of flowing water. The work of the Lake Survey, up to the time of the experiments here briefly described, contains no demonstration of this vital point."

And then there are tables given of tests of the accuracy of the Haskell Current Meter in the Detroit River, table LXVI, and with this conclusion:

"On June 1, 44 observations showed a mean velocity of 2.818 feet per second by the fluid and 2.806 by the meters; the meters giving a lower velocity by merely $\frac{1}{4}$ of 1 per cent.

On June 2, 32 observations showed a mean velocity of 2.922 by fluid and by the meters 2.933; the meters giving a higher velocity by about $\frac{1}{3}$ of 1 per cent. These small divergencies are the accepted errors of observation characteristic of hydraulic work. Individual observations show larger divergencies coming from fluctuating velocities. The tests demonstrate conclusively the correctness of the indications of the Haskell meters."

Mr. Adcock: The year was 1906 that the tests were made?
Mr. Wilkerson: Yes.

A. That evidence is in this case, testified to by Mr. Shenehon, and was given consideration, and I believe that for the conditions which are represented here those tests were about all that is claimed, but they were not tests made under conditions which the meter encountered in gaging the Niagara River, and therefore they do not apply.

Q. Were they made under the conditions under which the St. Clair River was measured?

A. In which the surface measurements of the St. Clair were made, they were reasonably comparable.

Q. How about the Detroit River?

A. The Detroit River would be the same; they apply to measurements near the surface of the stream.

Q. Do you attribute any part of the difference between the result which you have reached as to the increment for the St. Clair River and the result of the Lake Survey, to any inaccuracy in meter measurements; if so, what part of it?

A. Yes, I attribute some of it to inaccuracy in meter measurement.

Q. In your opinion, in what way would any inaccuracy of meter observations be reflected to a greater extent in the conclusions reached by the method of the Lake Survey, and those reached by your method?

A. I don't see that there would be any difference.

Q. Then why would meter observations have anything to do with the difference in the result which you have reached? I understand you have taken these observations and simply combined them by a different method; and have you eliminated the inaccuracy of the meter in the St. Clair, so far as any difference between your results and the Government is concerned?

A. For the value which I finally gave to the increment, I had in mind the possibility or probability, in fact I may say the certainty, of errors in the meter measurements.

Q. That is to say you took—

A. I allowed myself a variation of 10 per cent. in my mean.

Q. You made an increase of 10 per cent.?

A. I allowed myself a variation of 10 per cent. and gave the minimum figure.

Q. Why did you increase rather than decrease it?

A. Because all the information I had leads me to believe that these measurements are low.

Q. And you have no information on the subject except what appears from these reports and tests?

A. And from the experience of some 20 years on hydraulic work, in which I have been engaged in measuring water by various devices, current meters and others, comparing one device with another, studying the peculiarities of water under conditions where it could be studied to greater advantage than it has been able to be studied in these gagings.

Q. You never spent any time making studies at the International Bridge Section?
